LONDON, FRIDAY, JULY 4, 1862.

A FLOATING SANITARIUM.

THE unhealthiness of Calcutta, as a place of residence for Europeans, has made itself painfully apparent during the last few years, and has cost this country many valuable lives. The site of that city is, indeed, one of the worst that can be conceived. It was originally a dismal swamp, and drainage now is next to an impossibility. Calcutta is, however, to all intents and purposes the metropolis of British India, and the original mistake of founding it in so pestiferous a locality, entails upon its inhabitants a perpetual penalty, in the form of fever, or other deadly diseases. We question whether a single European whose fortune, or rather, whose fate, causes him, for any space of time, to become a resident, escapes an attack more or less virulent of the complaints peculiar to the plague-ridden place. Under these circumstances it becomes the duty of the Home, and Local Governments to do all that science can suggest, or practical experience dictate, to mitigate the evils which surround its inhabitants. We have known many instances of young Englishmen, engineers and others, who have gone to Calcutta only to find there their graves, or to be so prostrated by illness as to be compelled to return immediately to their native land, while the mortality among troops stationed there has passed into a proverb.

One very sensible movement is, we are glad to find, being made at Calcutta, as a remedial effort, and it is that of establishing at some distance from the city a floating sanitarium. This will be placed at the mouth of the Hooghly, within a day's sail of the capital, and not out of reach of the post-office and the electric telegraph. The steamship Bentinck, once so well known in the service of the Peninsular and Oriental Company, but some time since purchased by the Government for the purpose of transporting troops, is rapidly undergoing conversion into a sanitarium for invalids. Ere many weeks elapse, therefore, in all probability the old slow-going steamer will have become a great floating sanitary hotel, and be moored at the entrance to the Hooghly. The precise spot selected for this ark of refuge is, we are told, a creek near Hidgellee, where she will be exposed to the health-giving breezes of the Bay of Bengal, though partially sheltered from its storms, and surrounded by a fine sandy beach. The lower deck of the quondam steamer is being fitted up for the reception of invalid private soldiers, and the upper deck for such officers as have heretofore been accommodated in the Calcutta hospital, and for whom change of air has been recommended by the medical attendants of that place. The space on the ship hitherto occupied by the enormous paddle-boxes, and wheels will be devoted to the formation of baths, wherein the convalescent may daily disport himself in salt water, without fear of sun-stroke or the attacks of sharks.

While the main object is to receive military invalids on board the sanitarium, it is understood that the advantages accruing from its establishment will be open, on payment, to the general public, and thus there will be a chance of making it at least partially self-supporting. It will supersede the common, but unsatisfactory expedient of a run out to sea in an uncomfortable "tug," or a residence for a week or two in a small pilot vessel. Invalids who dread the sandheads when a gale is on, will be attracted by the prospect of a week's or a month's location in a sheltered sandy bay, and the fear consequently is that it may become too popular. We are assured that, if properly managed, the floating sanitarium will become a blessing to the people of Calcutta; and should the demand for its accommodation be found too great, another hulk may easily be provided as a supplement to the Bentinck. The tariff of rates for admission and attendance should be properly fixed, and books and amusements furnished for the semi-invalids. Boating in the creek, and walking exercise on the shore, ought also to be encouraged; but, doubtless, aids and adjuncts of various kinds will soon suggest themselves and be adopted. A small steamer will have to be in constant communication with the city and the ship, and regular postal and telegraphic arrangements should be made. Thus the overworked and over-anxious merchant or official who, though not positively ill, is in a fair way of becoming so, may take a run down to sea-quarters, and find "health in the breeze, and "shelter in the storm."

Those who know anything of life in Calcutta are aware that a facility of the kind described will be invaluable. A stay of a few days on board the Bentinck may save lives worth "a "king's ransom," or render it unnecessary for men, whose services are indispensable to India, to rush home in order to re-establish broken health.

Under these circumstances, we shall watch with considerable interest the development of the floating sanitarium, though there can be no doubt of its speedy and permanent success.

OUR DOCKYARDS AND ARSENALS.

THE systematic perversion by Government of facts and arguments relating to this subject is remarkable. Is the motive ignorance, indifference, or design? We have a strong impression, but we will not express it. Whatever the motive, the course taken by Ministers, in Parliament and through the press, has become a scandal. We will state facts, and leave our readers to judge whether we prove our assertion or overrate its importance.

Great surprise has been excited by the contradictions of official authorities on the results of target trials at Shoeburyness. They are palpable and disgraceful enough, but are easily accounted for. To answer the purposes of Government, two results of a completely opposite character had to be proved from the same experiments. The power of resistance of the Warrior target and the penetrating effect of the Armstrong guns had both to be established. This was an unlucky dilemma, and betrayed the authorities into misrepresentations which have damaged their reputation and broken down their case. The natural indignation of the public, plainly expressed in the House of Commons, compelled the Government to abandon the Spithead Forts.

The House, having condemned fixed forts, has recorded its opinion that they are not the right kind of defence for the entrance of the channel leading to Portsmouth harbour; but, in coming to that conclusion, it does not deny the necessity of defences at that point. On the contrary, the House is of opinion that the effectual defence of the Channel is a matter of paramount importance. Government are of the same opinion, and, so far, nobody dissents from the Defence Commissioners, who are unanimous in recommending that the Spithead Channel should be strongly protected. The country, which begins to understand the question, is willing to grant any sum necessary to guarantee the safety of Portsmouth Arsenal and Dockyards, and the immense fleet in ordinary or in dock in that harbour. It is politic and patriotic to fix Government with that responsibility. This point being determined, the debate is narrowed into a small compass. The channel between the Horse Sand, No-Man's-Land, and the Sturbridge Shoals must be protected. If Ministers now deny that necessity they will stultify themselves, and leave the country to believe that the plan of erecting fixed forts on those frail foundations was a proposal for a monstrous job. We do not believe such an intention existed. We believe ministers were convinced by the Report of the Defence Commissioners, that the most urgent duty of the War Department and the Admiralty was to defend the important channel at Spithead from an attack by sea.

The House, by its vote, has decided that fixed forts are not the right sort of defences, and that floating batteries are. Parliament, to be consistent, should order that the sums saved from being wasted on the former should be usefully appropriated to the latter, for a purpose which all parties agree must be effected. By this course ministers will be fixed to the real question, and they will not succeed in entangling the House in a general discussion.

The distinction should also be drawn by members, who understand the subject, between ships and floating batteries, which it is an artifice of ministers to confound, as if they where the same thing, whereas they will differ as much in their form and construction as a fixed fort differs from a ship, with the sole exception that the fort is not afloat.

Another artifice of Government, which requires to be exposed, is their attempt to create confusion relative to harbour defences on the land side and on the sea side. It is obvious to reflection that these two modes of protection are wholly independent of each other, as regards operations near the *Shoals*, where the Spithead Forts were proposed to be erected; so that any idea of land defences in that direction is simply ridiculous.

What is the use of raising issues or arguing points on which there is no difference of opinion? Government, knowing their case is bad, are unwilling to meet their adversaries on fair ground. Unable to offer any good reasons in support of their object, they endeavour to mislead by turning attention aside from the real question, and directing it to other matters about which everybody is agreed. If you cannot carry your point with your opponent by a direct attack, make a feint, try to deceive his vigilance, and steal a march upon him. These are the tactics of ministers. Defence on the land side—the construction of monster guns which will pierce iron plates at 2,000 yards—the capability of land forts to mount guns which ships cannot carry—protection against invasion,—these and other collateral points are raised, confounded, and discussed with simulated earnestness, as if they were the main question, when in fact they are quite beside it.

It may, however, be worth while to answer some of the fallacious arguments on the ministerial side. One case supposed is war with a maritime power having a navy able to cope with our own, and the danger to be guarded against is represented to be a landing on our coasts. At the moment of the threatened invasion our chief dependence must be on our fleet, to repel the aggressors. In any state of things, however well prepared we might be, all our resources would be put in motion to increase our naval armaments. At such a time the protection of our dockyards and arsenals from an attack on the side of the sea would be a supreme necessity; and if the

approach to those centres of our naval power were accessible to an enemy, they would become the first object of attack as a preliminary to a landing on our coasts. If he could enter Portsmouth harbour, he would do so, and by destroying our ships fitting in that port, he would prevent us from using the force which might render invasion impossible. Under these circumstances we ask which would be the best defence to the channel—fixed or floating forts?

The propriety of inland defences to our dockyards is not denied by the opponents of the Government proposals. It is only on the nature and extent of the works that opinions differ. But, however that may be, the necessity of land defences does not render the defences on the side of the sea less urgent. Of what avail would land defences be, if the Spithead Channel could be forced by a squadron of armour-plated vessels which might speedily destroy every vessel in the harbour or the dockyards? And be it remembered that this work of destruction could be accomplished by a few invulnerable gun-boats, if they succeeded in passing by the defences of the sea channel, as the Federal gun-boats did in the Mississipi.

We have now to consider which is the best kind of floating defence to an estuary or channel more than 1,000 yards across, leading to the harbour or arsenal to be protected. Many writers and speakers on this subject fall into a confusion of ideas, by not making a proper distinction between sea-going ships and floating batteries, or between the defence of a broad channel and a narrow river. Hence has arisen much misunderstanding of several important points. The forts, whether fixed or floating, are "*points d'appui;*" they are not the main line of battle, but supports to fighting ships. Whichever description of support is adopted, there must be a fleet of line-of-battle ships and gun-boats in addition. This necessity is foreseen and provided for in the Defence Commissioners' Report. These vessels are to do the active fighting part of the business; and if we are to be protected from hostile invasion, the "financial absurdity" of constructing these vessels, so much deprecated by the *Daily Telegraph*, must be perpetrated. Forts or no forts, we must possess so large a fleet of sea-going iron sides, moveable from port to port, that "we can bring to every accessible point of the "coast as many of those vessels as an invader "can bring against us."

The object of the bill before the House, as its title and provisions show, is the "defences "of the royal dockyards and arsenals." Its object is not the general defence of the country, and, therefore, notwithstanding Sir C. Lewis's ingenious sophistry, to import into the debate questions of invasion and landing on exposed parts of the coast, has no other object than to divert attention from the consideration of the most efficient means of defending our dockyards, which is the real matter for debate. The premier himself settled this point decisively, by the concluding words of his speech. "These "fortifications," he said, "are necessary to "defend the dockyards, which are essential to "the maintenance of our navy, that navy being "necessary to the country as an independent "nation."

To determine the relative value of these defences on the land side or on the sea side is a fair subject for controversy; but at this moment their relative urgency rather than their ultimate utility has to be decided. On this point we will confine our remarks to Portsmouth. It is our most important arsenal, and the principles which prevail there will be applicable to the other places mentioned in the bill. In the estimates a given sum is set down for Portsmouth. We will not stop to consider whether it be too much or too little. The point to determine is, "shall the sum, or the greater part of "it, be appropriated to works on Portsdown-hill, "and other points inland, or to floating batte- "ries in lieu of the forts intended to have been "erected on the Shoals at Spithead?" Should this question be put to the vote, if the House is consistent with its decision, which compelled the Government to abandon advanced forts, there can be no doubt there will be a large majority in favour of the floating batteries.

That question being carried, it should be followed by a resolution, declaring that two or more floating batteries are indispensable for the defence of Portsmouth harbour, and appropriating a sum for their immediate construction. Ministers cannot venture to oppose this resolution, at least to the extent of the sum intended to be applied to the Spithead Forts, as that sum will be disposable out of the £1,200,000, and it will thus be applied most efficiently for the defence of Portsmouth at this vulnerable point, which it is the main object of the Defence Commission and of Government to accomplish.

If ministers are pinned down to the real question by this course of proceeding, they will be driven to a surrender of their opposition to floating batteries, as complete as the abandonment of their plan for the construction of the Spithead Forts.

PATENTEES IN PARLIAMENT.

WE beg to call attention to an Act of Parliament which has just been passed, intituled, "An Act for rendering valid certain letters "patent granted to Thomas Webb, of Tulbury, "in the county of Derby, cotton spinner, and "James Craig, of the same place, manager."

It appears that letters patent were granted to Messrs. Webb and Craig for "improve- "ments applicable to spinning, doubling, wind- "ing, and warping yarns or threads," the 30th day of July, 1858. One of the conditions of the grant of the letters patent was that a stamp duty of fifty pounds should be paid, and the letters patent, stamped with a proper stamp, should be produced at the office of the Commissioners of Patents before the expiration of three years (30 July, 1861) from the date of the letters patent. The stamp duty was not paid, and the letters patent were not produced within the prescribed period; consequently the letters patent became void.

In the preamble of the Act, it is stated that the "non-payment of the stamp and the non- "production of the letters patent duly stamped "within the time limited for that purpose, "arose from inadvertence on the part of the "person employed by the said Thomas Webb "and James Craig to take the necessary steps "for payment of the said duty and production "of the said letters patent."

We hold Messrs. Webb and Craig and their agent to be inseparable in such a case; and as there was so long a period allowed for the payment of the stamp duty, we think the grounds upon which this expired patent has been resuscitated by Act of Parliament wholly inadequate. It is a most dangerous precedent, and may tend to make patentees careless of their own interests; for should the parties whom they employ and entrust with the necessary fees to effect the extension of the term of their patents betray their trust, they will fancy they can do as Messrs. Webb and Craig have done, and get a special Act passed for them.

What machinery may have been set in motion to get the Act passed, we are at a loss to conjecture; but we certainly think that the time of the legislature might be better occupied than by passing Acts to remedy the injury occurring to private parties through their own laches.

INSULATION FOR DEEP SEA CABLES.

INDIA-RUBBER.

THE report of the Board of Trade Committee, and the evidence of several eminent personages who attended before that body, had given rise to a hope that at some distant period, when experience had waited upon theory, india-rubber, in some form or other, might have taken its place by the side of gutta-percha, as a valuable addition to our material for insulating cables. Not that we supposed, under the most favourable circumstances, india-rubber would supersede gutta-percha in practical value; our endeavour in treating of the subject having ever been to hold the balance fairly between the two substances, simply inculcating caution and tentative action as regards the newer insulator before launching into its use for works of any great magnitude.

That this mode of dealing with the matter was the right one, as regards the deep interest which the public have in the future of long sea cables, is abundantly shown in a paper recently read by Mr. C. W. Siemens before the Institution of Civil Engineers. From the contents of that paper, its author, whose evidence before the Board of Trade Committee was strong in favour of india-rubber as against gutta-percha, would seem to have much modified his views in regard to both substances. He now, from further experience, has been enabled to perceive the advantage of that quality in gutta-percha which enables it to "*be put upon the wire in a plastic "state by a die process, giving greater security "against faults than the lapped india-rubber "covering. It is also,*" he says, "*less liable to "become sticky or semi-fluid when exposed to the "atmosphere, and resists the action of water more "perfectly.*" This ought surely to be conclusive in favour of the material so acting, especially as the supposed inferiority of the gutta-percha, as regards its inductive and insulating properties, has been completely set at rest by Professor Wheatstone, who writes to the Board of Trade Committee that pure gutta-percha (as it is now manufactured) closely assimilates to india-rubber in both these respects. It seems, therefore, somewhat illogical in Mr. Siemens to recommend as he does the union of caoutchouc and gutta-percha. Having, however, given his own opinion as to electrical advantages of india-rubber, he proceeds to say, that notwitstanding these assumed advantages, "*its gradual disso- "lution in sea water was a circumstance which "alone rendered it inadmissible for submarine "wires, unless it was securely inclosed in "another waterproof medium, and gutta-percha "appeared in every respect well suited for such "outer covering.*" An advantage of some importance, as regards cables for warm climates, is certainly claimed for india-rubber, namely, the power it is said to have of resisting heat; but in the next paragraph Mr. Siemens gives a particular caution against the application of heat in the process of covering the wire with rubber, as he says, "*it often entailed a gradual decom- "position of that material.*" Now, in addition to climatic heat, the rubber in the cable proposed by Mr. Siemens would be exposed to direct heat in the very application through the die of the gutta-percha, which is admitted to be required for its preservation.

One is, therefore, tempted to say "*cui bono*" to all this. Where is the use of incurring the large extra expense involved in this compound process, when the result is so practically untried, and so very problematical, that we our-

selves have seen a piece of insulation, in the form under discussion, wherein the two substances appeared as if through some antagonism in their respective natures they were in course of mutual decomposition? We do, at all events, know many important facts about gutta-percha. It improves by submersion in the sea. It is admitted on all sides to be an excellent insulator. It can be applied with the greatest facility; and there are somewhere about 10,000 miles of gutta-percha covered submarine telegraph wire in cables, which have worked well during several years, and show every possibility of continuing to do so.

LONDON MECHANICS' INSTITUTION.

WE are sorry to find that the above institution, which is by no means creditable to the mechanics of London to say, has contended against pecuniary difficulties for some years past, is now threatened with proceedings in chancery and proximate dissolution. This has arisen from a claim made for the payment of a mortgage debt of £1,500, recently incurred by the purchase of the premises. We cannot but feel greatly concerned that an institution which has effected so much good, should be thus placed in jeopardy, and we trust that some means may be devised for extricating it. No doubt the formation of relative institutions has had much to do with the difficulties past and present of this, the parent of them all, but we do not think that the advantages it offers, to *young* men especially, have been commensurately availed of.

We can, however, point to many instances where the evening classes and lectures, at the London Mechanics' Institution, have produced excellent fruit, and we know many men in high positions who owe their success largely to the early influences of the institution. On these grounds and others, then, we commend the Mechanics' Institution to the mechanical classes of the metropolis, and trust that a large accession of members may be the result of our appeal.

A committee has been formed with a view to raising the sum necessary for relieving the establishment—the people's college, as it may be termed—from the legal pressure which now weighs it down. Donations to this aid are received by various bankers, including Messrs. Smith, Payne and Smith; Messrs. Hanbury and Lloyd; Messrs. Ransom & Co.; at the Birkbeck Bank for deposits, and at the London Mechanics' Institution, Southampton Buildings, Chancery Lane.

LIFE-PRESERVING APPARATUS, &c., IN THE INTERNATIONAL EXHIBITION.

THE ladders and uncovered baskets whereby men formerly passed into collieries are now being gradually replaced by safety cages. Before describing those shown at the International Exhibition, it may be remarked that the object of these apparatus is to protect life if the rope or chain raising or lowering the miners should fail, or any debris or gearing should fall into the shaft. There is no law to compel proprietors of collieries to use safety cages. The Act on manslaughter would probably reach the owners of any mines where lives should happen now to be lost by the breaking or overwinding of a chain. A very distressing accident of this kind occurred in 1860, at Earl Granville's colliery, by which a number of men were killed through the overwinding of the rope of the ascending cage. In the previous year between one and two hundred people lost their lives, according to the colliery inspectors' reports, from causes which would have been obviated by the general use of safety cages. The principle of nearly all safety cages is the freeing of one or more levers which press against the guide rods fixed to the side of shafts, when the hauling tackle is not stretched by the chain. Mr. J. T. Calow exhibits in Class 1, No. 52. The improvement claimed in this invention is that the levers or grips are not disengaged whenever the cage is supported, as by resting on the ground. This apparatus has been beneficially in use for some time at the West Staveley Colliery, the viewer of which, Mr. Moody, states in writing that it has preserved life on three occasions. In the open court, Class 1 (which contains many objects of interest), there is erected in full size working order Aytoun's patent safety cage, described in a previous number. Mr. W. Heath Jordan likewise exhibits a model of a pit frame and safety cages.

For the raising and lowering of goods through the different floors of warehouses, and at railway stations to and from the platform, as at Bristol, the miners' cage is used. The patent Hoist Company, in Class 10, exhibit a safety cage which is designed to obtain the same result by an arrangement brought into action by centrifugal force. Watts's governor regulates the velocity of the cage in transit. The advantage obtained by this mode is that when a chain breaks the cage gradually descends. Patent cages on No. 52 principle could easily be constructed to enable the inmates to lower themselves on a chain breaking. Mr. George Dodman shows also, in Class 10, a patent safety hoist. The cage in this instance becomes stationary whether the chain breaks or is overwound. Messrs. Marcus Brown & Co. also show a safety cage.

The many contrivances invented for affording relief to the inmates of houses on fire have been well represented for some years past at the annual Exhibition of the Society of Arts. They principally consisted of chain ladders for attaching to upper window sills cages with incombustible curtains, lowered by cranes inserted into eye-bolts fixed in the wall. Some houses have still facilities permitting egress over the roof to the adjoining residence in cases of fire. These are all being superseded by the ladder fire-escapes; none like the two to be seen at the present Exhibition was shown in 1851. Mr. Clarke's improved fire-escape, Class 10, reaches 80 feet high. The underneath part of the centre ladder of this fire-escape is encircled by canvass rendered incombustible by being saturated in alum and chloride. A wire gauze further protects the canvass from the effects of flames. Into the wooden steps of the ladder are inlaid wire rope, sufficiently strong to bear the weight of several men. The improvement in Clarke's fire-escape is in the lever bars for raising the second ladder, which work on quadrants. This arrangement prevents a reoccurrence of the Bishopsgate-street accident, when the levers broke; falling on the people. All the lives in jeopardy were saved on this occasion. This fire-escape is so light that one man can wheel it easily. The Royal Society for the Protection of Life have purchased this fire escape for their station in front of the Royal Exchange. Messrs. Merryweather and Son exhibit in Class 7, No. 1928, a fire-escape constructed similar to those to be seen in many of the principal thoroughfares at night.

The mariner's daily risks appear to equal those of the miner. The sympathy for the former is displayed by the Royal National Life-boat Association, who possess a prominent stand in Class 12, containing models of rowing and sailing life-boats. Mr. Richardson shows a highly finished model of a patent tubular life-boat. Another inventor, Mr. Coryton, his vertical wave line system and atmospheric guide propeller life-boat. The noted life-boat named the Mary Anne, belonging to the ports of Hartlepool and Sunderland, is represented by a beautiful model. This boat was subjected some years since to many tests in Ramsgate harbour, and fully showed its capability of being able to right itself immediately when purposely capsized, particularly in the instance when the boat was under sail. The crew of the Mary Anne have received, since 1857, the sum of £250 from the Board of Trade, for saving life, besides salvage money for assisting vessels in distress.

The noble family of the Phipps date their rise from a man in a very humble calling, who formed the singular project of recovering the treasure sunk in a wrecked vessel, though the ship had been lost some sixty years before, on an uninhabited part of the American coast, rumour only pointing to its precise locality; yet this remarkable man, after years of labour, accompanied with great disappointments, finally succeeded in recovering a large amount of the long lost treasure. The diving apparatus so efficiently used to recover the gold in the Royal Charter, suggests whether it might not be beneficially used to obtain from the sea valuable property hidden many ages on different parts of the coasts. Heinkes's patent diving apparatus, No. 2296, Class 10, was employed for removing the old foundations at Westminster bridge, and is stated to have been in constant use for five years without any accident having occurred. Adjoining is "A. Siebe's" diving apparatus, used in the summer months from 1839 to 1844 inclusive, in clearing the anchorage at Spithead of the wrecks of the Royal George, of 104 guns, lost whilst engaged in partially careering the vessel in 1782, and the Edgar, of 70 guns, blown up and sunk in 1711. There is a very interesting copper pulley wheel shown, recovered from the wreck of the Mary Rose, sunk in the reign of Henry VIII. The workmanship and skill used in order to combine strength and lightness in this pulley wheel is remarkable; no improvement thereon could be effected at the present day.

GEORGE WALCOTT, C.E.

THE INTERNATIONAL EXHIBITION, 1862.

AMONGST the exhibitors in pipes, Mr. J. Chatterton, of Wharf-road, City-road, stands prominent in the scale of excellence (Class XXXI., No. 6376). He shows lead, composition, and pure block tin pipes of every variety of size and shape, and of the most perfect manufacture. Ordinary lead pipes of all sizes, from 1-32nd of an inch to 6 in. diameter, lead mouldings, polygonal, and multiple pipes, the latter being used for the purpose of conveying various liquids into spirit vaults, and are enclosed in the large pipe for neatness of appearance and facility of fixing on walls and down angles, &c. The three pipes combined are especially designed for domestic purposes, the object being to convey to the different parts of the house hard and soft water and gas. Lead pipes, coated internally with pure tin, for use in those localities where the water forms poisonous salts with the ordinary lead pipe. Lead pipes are shown, lined with gutta-percha, for similar purposes as last named. These are also, by their lightness and remarkable strength, particularly suitable for conveying water in mountainous countries, where they would have to sustain a great pressure; and, from the frost-resisting properties of the gutta-percha, they are invaluable in cold latitudes. Brass union joints are exhibited, showing that the lengths may be connected as easily and as perfectly as ordinary lead pipes. Composition tubes for gas, which show a great superiority in material and manufacture, and placed by the side of tin tubes, not only rival them in brilliancy, but are found also to equal them in hardness and toughness. The pure block tin tube is deserving of especial notice. The specimens here exhibited are quite unequalled. The upright, 10ft. length, 3in. internal diameter, is the largest size ever made in long lengths; it is as smooth and bright inside as outside. Mr. Chatterton also exhibits specimens of cylindrical projectiles for smooth-bore guns, which are intended to obviate the necessity of using a rifle-barrel, with its tendency to fouling, and at the same time to secure that force and accuracy which under ordinary circumstances are only attainable by the use of the rifle. Instead of receiving a rotary motion, as heretofore, from a grooved barrel, it derives it from the resistance of the atmosphere acting upon a suitable helical apparatus in the bullet itself. The projectile is in shape a hollow cylinder, open at both ends, and the internal screw is made of different patterns, which can only be understood by a personal inspection. Altogether, the collection of samples exhibited by Mr. Chatterton is very com-

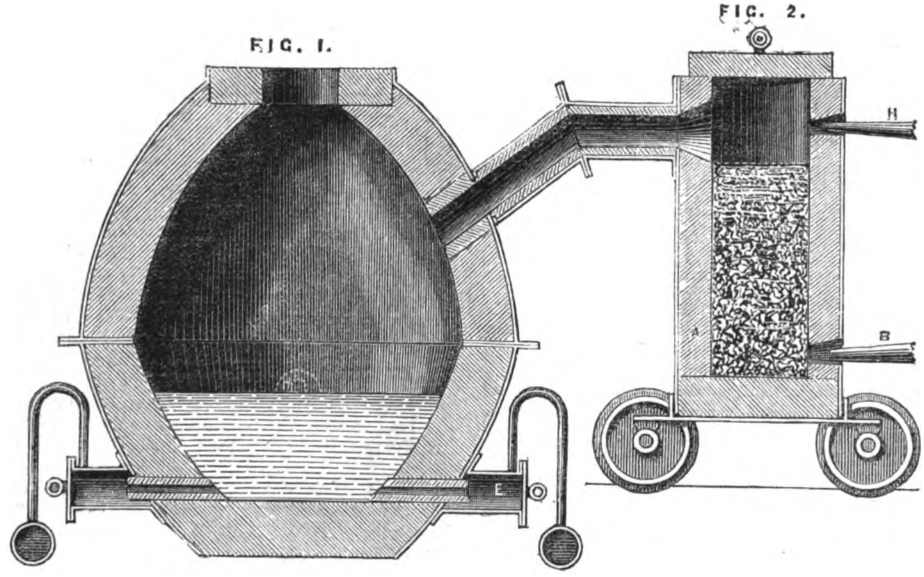
ple'e and interesting, and shows especially the perfection to which the art of pipe-making has arrived in this country.

SHIPS' RUDDERS.

An interesting trial recently took place at Portsmouth of a plan, patented by Captain Warren, R.N., for steering ships under steam by a rudder placed in the vessel's bow. The chief merits claimed by Captain Warren for his patented rudder are that it is an auxiliary steering power to the ordinary rudder, assisting the ship to turn quicker when necessary, as might be the case under the fire of an enemy's battery, and also that it should replace the ordinary rudder in the event of any accident happening to the latter, either from the weather or the shot of the enemy. The vessel with which the principle was tested was the Princess Royal, a small paddle steamer belonging to the Portsmouth and Isle of Wight Steam Packet Company, and to the bows of which a rudder had been temporarily fitted. The rudder had, however, an area of only nine feet, or one-third that of the vessel's ordinary rudder aft. It was also evidently placed too far forward, and was not sufficiently immersed, the upper part of the rudder being some nine inches above the water line. In fitting a bow rudder to a man-of-war, Captain Warren proposes to have the upper part of the rudder 15 feet below the water line in a vessel drawing, like Her Majesty's ship Defence, 26 feet of water, and other ships in proportion. It is evident, therefore, that the principle, although certain favourable results were obtained, could not be fairly tested; that is—that with an increased area and submersion of the rudder, and an alteration of position, its power would have been more fully developed. Captain Broadhead, R.N., conducted the trials. Among the gentlemen on board to witness the trial were —Admiral Sir H. D. Chads, Captain Fullerton, R. N., Mr. A. Heather, manager of the United Steampacket Company; Mr. Reed, manager of Messrs. White's shipbuilding-yard and slipway, &c. The first trial was made by placing the after or ordinary rudder of the ship hard over, when the ship made a complete circle in 3 min. 22 sec., the engines making 27 revolutions. In the second trial the forward rudder was put hard over; but the vessel was so long in making the half-circle that this trial was abandoned. In the third trial the forward rudder was put hard over, and the after rudder fixed amidships with chocks, when a circle was completed to port in 6 min. 19 sec., the engines making 26½ revolutions. In the fourth, the forward rudder was again put hard over, but this time with the after rudder loose, when the time occupied in completing the circle, the steamer coming round in this instance also to port, was 8 min. 24 sec., the revolutions of the engines being 26½. In the next trial the after rudder was put hard over, with the forward rudder loose, and the ship made the circle to port in 3 minutes, the revolutions of the engines being 26. Both rudders were next put hard over together, when a circle was completed to port in 2 min, and 47 sec., a gain of 13 sec. on the preceding trial, the engines making 24 revolutions. When the ship stopped dead, the after rudder was put hard over and forward rudder fixed, when the engines were turned ahead, the time being taken from their moving fairly ahead. Circle computed in 3 min. 37 sec. The same experiment was next carried out with the forward rudder, when the circle to port was completed in 6 min. 40 sec., the revolutions of the engines being 25½. Forward rudders, like screws, require lengthened and expensive experiments to develope their powers, and are almost beyond the means of private individuals. There is, however, no doubt considerable merit attached to the plan proposed by Captain Warren, but the experiments require to be carried out on a larger and more perfect scale.

PARRY'S STEEL FURNACES.

FIG. 1. FIG. 2.



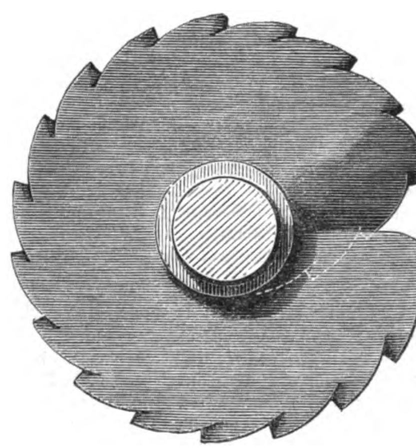
MR. G. PARRY, of the Ebbw Vale Iron Works, Monmouth, has patented an improvement in the manufacture of iron and steel. The above engravings show in sectional elevation a furnace or receiver for making hard or soft steel in large masses for casting purposes. The invention consists in blowing air through the fluid metal for the purpose of reducing it to any degree of softness.

E E are two blast boxes, of which there are several placed round the furnace. They are made either cylindrical to hold but one tuyere each, or are widened out around the furnace so as to hold a greater number. The main blast pipe is connected to the blast boxes by suitable pipes; there are two tuyeres for blowing air through the molten metal, and *H* the tap hole for discharging it when reduced to the required degree of softness. This furnace or receiver is made of a curved or parabolic form, as shown, and lined with fire-resisting material. The charge of hard steel or carburetted wrought iron is run in a molten state into the furnace through the opening at the top after the blast has been turned on.

The furnace may conveniently be heated by means of a gas blow pipe, as shown. *A* is the fuel chamber of this blow pipe, charged with breeze, or refuse from the fires, together with a portion of lime to flux the clinker and ash, and which runs out at the cinder hole; *B* is a blast pipe for generating the gas, and *H* another for effecting the combustion of the gases while passing through the pipe to the furnace; or the blast of air for consuming the gases may be introduced directly into the pipe. This gas furnace is lined with fire-brick and closed with a cover, or it may be surmounted by a charging hopper. The pipe is also lined with loam or other bad conductor of heat. This gas blow pipe is mounted on wheels for the convenience of removing it to and from the furnace when desired. After a few minutes blowing into the receiver (the exact time requisite being very accurately ascertained by the workman after a little experience) the steel will have become sufficiently softened, and may be tapped and run out into a funnel and dealt with as necessary. Previously to tapping, the furnace alloys may be run in at the top, or, what is better, the alloying material may be poured into the funnel as the steel is running. It may also be hardened when made too soft by the addition of hard steel or of any pure pig or carburetted iron (which may also contain the alloy) in the same manner.

In the manufacture of cast steel direct from crude pig iron, as lately introduced by removing a portion of the carbon, sulphur and phosphorus remain behind, and it is difficult to get crude pig iron free from these injurious elements. In this process for manufacturing cast steel by adding carbon to wrought iron (which had previously been puddled) nearly all the pig iron produced in this country becomes available for the manufacture of cast steel in this converting furnace, the greater proportion of the sulphur and phosphorus originally contained in the iron having previously been eliminated in the puddling process.

JOHNSON'S EARTH SCREWS.

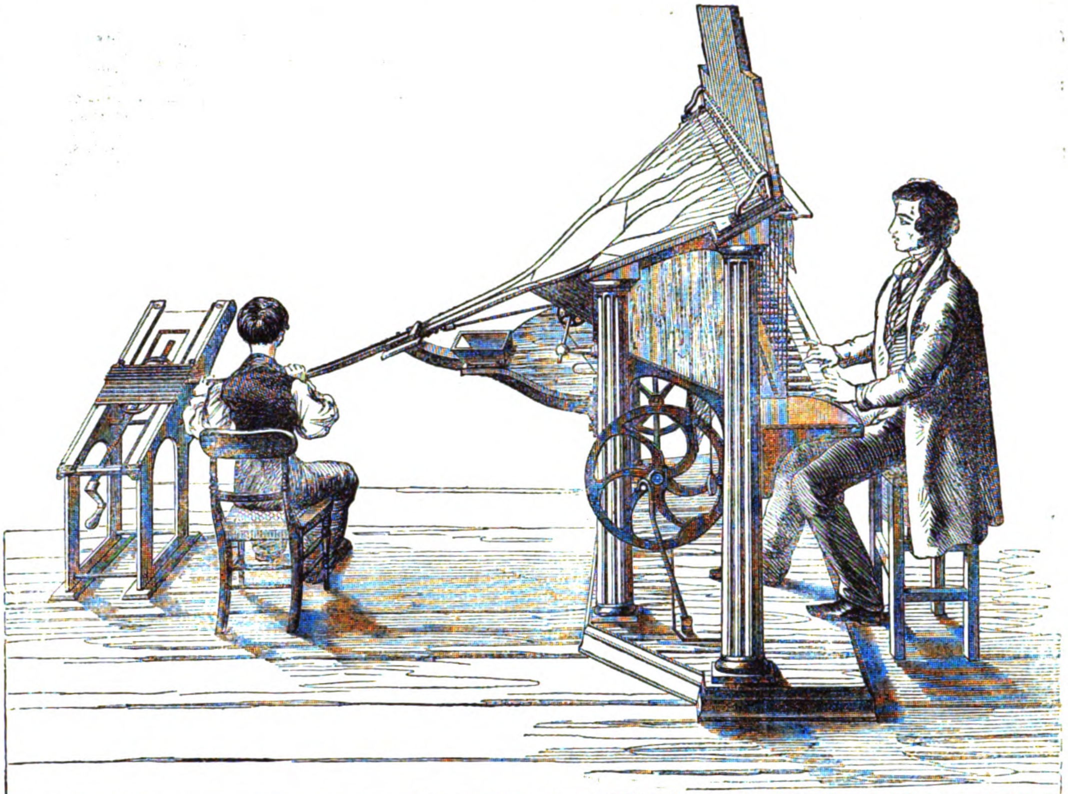


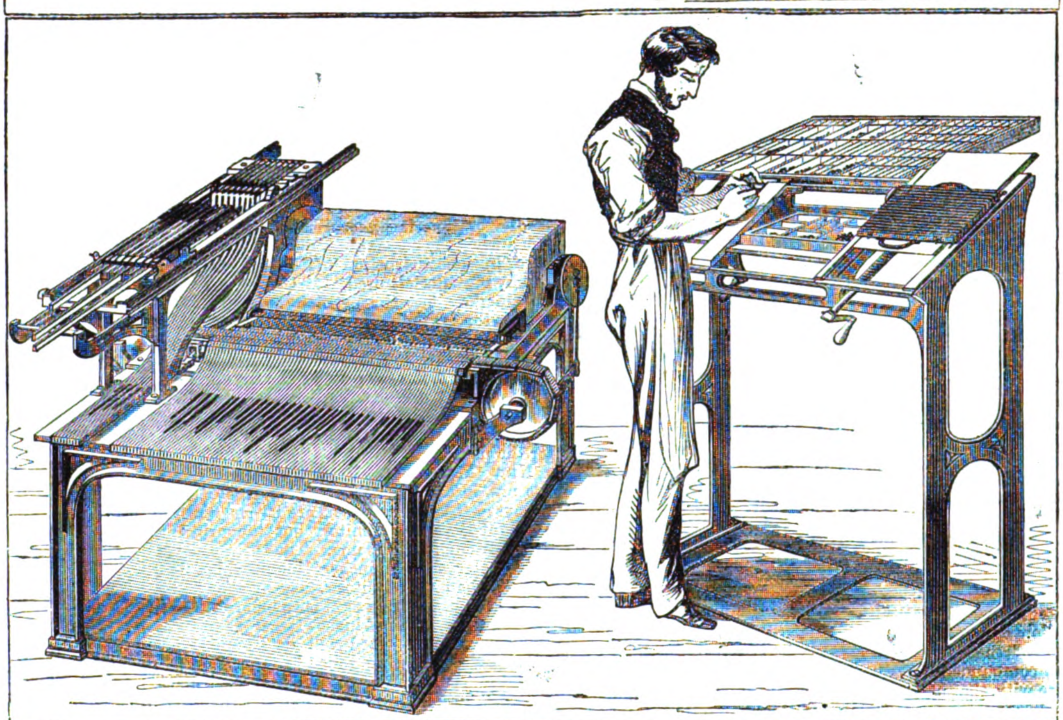
THE annexed engraving illustrates a screw suitable for pile and other foundations. The invention consists in making the periphery of the flange of the screw with a number of teeth similar to a circular saw, as shown, and arranged so as to assist the pitch of the screw, thereby enabling it to cut its way into the ground with greater facility than those at present used with a plain and unbroken flange, or the screws may be made by having only a portion of its periphery with teeth, and in this case a projection would be made at its cutting edge, so that the remainder of the screw, which is of a lesser diameter, would follow in the opening made by the said projection.

This invention is patented by Mr. F. Johnson, of North-street, Westminster.

The petition for the prolongation of Stirling's patent for the manufacture of iron for railway lines, was heard by the Judicial Committee of the Privy Council on Wednesday last, and dismissed.

YOUNG'S PATENT TYPE COMPOSING MACHINE.





THE inventor says that this type composing machine is provided with separate compartments called "reservoirs," for all the letters of a fount, and each reservoir is provided with a small lever, which, by means of a rod, is connected to a key like those used in a pianoforte. When a key is struck by the player it pushes a type out of the reservoir by means of the lever mentioned above, and the type is thus caused to slide down an inclined plane, and thence into a receiver, where it is set up side by side with other types, by means of a beater. Thus each type or letter can be set up by a player in the order required by a compositor's copy. This is now done with a speed of from 12,000 to 15,000 types set up in an hour's time.

The justifying apparatus is intended to replace the compositor's stick. The compositor places the galley filled with the long lines of type set up by the composing machine, slides one of them into the apparatus, divides it into the proper width of the page, and having justified it, moves a handle which depresses the completed line, and thus makes room for a succeeding one. It is found that a compositor can, by this means, justify at the rate of 4,000 to 6,000 types per hour.

The distributing machine separates all the different letters of a fount that may have been used for printing into different channels ready for use in the composing machine. This is effected by one or more pairs of nippers, which takes every type singly from the reservoir in which all the types have been placed, and allows it to slide down an inclined plane, the upper part of which moves on a hinge. The thin or lower-case types slide down to the bottom of the fixed inclined plane, but the thicker or upper-case letters are retained on the moveable incline, which, on being raised, drops them into an appropriate receptacle, whence they are then taken and re-distributed by passing down a separate channel of the inclined plane. The thin or lower-case letters that have arrived at the bottom of the inclined plane are pushed into the grooves of a revolving chain. This chain in moving passes underneath plates which are made of different widths in order to cover only certain nicks cut or cast on the edge of the types, and situated in different parts of their length, from 1-16th to 12-16ths of an inch from the tail of each type. When, therefore, a type passes underneath a plate which allows its nick to be exposed, it is pushed from off the chain by means of a scraper which passes over the plate on to a tilting inclined plane. This plane in its descent allows the type to slide down, by means of an inclined channel, into a receiver, where it is set up by means of a beater, as in the composing machine. The distinguishing nicks are somewhat like those used by type-founders; 71 per cent. of the types require only one nick, 20 per cent. only two nicks, and the remainder have three nicks. One distributing machine, attended by two boys, will distribute and prepare for the composing machine from 14,000 to 18,000 types per hour. A saving of 50 per cent. in the cost of composition is said to be effected by the use of these machines.

The machine may be seen at work daily in the International Exhibition, Class 7, and further information may be obtained at 77 Fleet-street.

A second edition of "The Fleet of the Future in 1862, or England without a Fleet," by J. Scott Russell, Esq., F. R. S., has just been published.

A novel trawling experiment will take place in a few days, by means of a steam fishing vessel, lately fitted up at Leith. Her trawling gear, which is very heavy, is intended to be wound up by a capstan driven by steam power, and all living fish thus taken will be put into a well, or salt-water aquarium, having a constant circulation of water through it; and thus the fish will be kept in existence until brought to market. We believe this to be the first direct application of the steam-engine to the purpose of catching fish, and the latter will soon have to contend against machine as well as hand labour. Whether they will "hold meetings and protest" against its introduction, remains to be found out.

TO CORRESPONDENTS.

Received.—T. W. B., T.F., W. E., M. and Son, J. and G., W. H. T. (two letters), D. M., R. E., J. H. H., J. N., J. W., W. A., W. F., R. A., J. B. B., W. W., D. M., W. E. M., G. S., R. K. P., J. H. E., J. H. J.

The letter of "Civilian" will appear next week, when the communications from several correspondents will be noticed.

PERCUSSIVE FORCE COMPARED WITH PRESSURE.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—Some years since an experiment was tried in Portsmouth dockyard, with a view to compare percussive force with pressure.

Through a block of sound oak was bored a hole one inch diameter; into the hole was inserted an iron bolt, which fitted very tightly. An able-bodied shipwright drove the bolt into the block by striking on the head of the bolt with a maul weighing 18 lbs., its length of handle being 45 inches. Every blow of the maul sent the bolt into the block about a quarter of an inch. When the bolt had been driven in some inches it was submitted to pressure, and it bore one hundred and five tons before it yielded; a few hundred weights beyond the one hundred and five tons set the bolt in motion and forced it close home.

Momentum, or percussive force, is not simply as the weight of the body multiplied by its velocity, but it is as the weight of the body multiplied by the *square* of its velocity. A cannon ball moving with a velocity of 2,000 feet per second, has four times the momentum of a cannon-ball of like form, and equal weight, moving with a velocity of 1,000 feet per second.

Falling bodies acquire accelerated motion by the force of gravity. At the end of the first second, a body so descending will have acquired a velocity of 32 feet per second (disregarding a small fraction); and as the velocities acquired are as the times of descent, and as the spaces passed through are as the squares of the times of descent, the space passed through being at the end of the first second 16 feet, we have $\frac{2000}{32} = 62{\cdot}5$ seconds time of descent to acquire a velocity of 2,000 feet; and $62{\cdot}5^2 . 16 = 62{,}500$ feet the space passed through in 62·5 seconds; a velocity of 1,000 feet would require the body to be dropped from a height of 15,625 feet. In each case the body is supposed to descend in vacuum; but in a body descending through the atmosphere, by force of gravity, such a velocity is not attainable.

John Harvey, Capt. R.N.

Cheltenham, June 18th, 1862.

THE STRAIGHT LINE *VERSUS* THE WAVE LINE FOR VESSELS.

Sir,—Permit me a few words only in reply to Mr. Moy. I have great respect for this gentleman, for the excellent good sense which his communications generally display; but I must be excused from complimenting him on his scientific acumen, at least, until he disproves and not simply denies my reputation, as I deem it to be, of the wave line theory for vessels. He says that "the curves used are *not* parabolic curves." I implied the same in part when I said that they gradually merge into straight lines as they approach the surface of the water (this is a concession to practice), but elsewhere in the hollow moulding of the bow they are employed, and I suppose with rigorous exactness, for the theory demands it, the theory of equal increments of velocity in equal times, but with decrements thereof as the hollow curves merge, by being softened off, into the lines of the side of the vessel. I suspect Mr. Moy has confounded the merging of the lines in the one case with that of the other. The real point of the matter is this: Is acceleration of any kind, uniform or otherwise, the object aimed at, or at any rate the effect produced by hollow lines, whatever may be their character? This leads me to remark that "the novelty of the idea" I am charged with claiming, is not in proposing straight lines for bows of vessels, but in proving that such lines present the minimum of resistance, and that hollow lines increase it. Mr. Moy must have overlooked what I said in regard to the tensile strain on my proposed vessel being met, "by having longitudinal strakes of iron on the interior surface," or he never would have made the remark that my "mode of ship-building could not possibly hold together." These strakes could, of course, be multiplied and increased in thickness to any amount of strength which the structure might require. But I pray him to have patience for awhile until the whole of my scheme, so far at least as it would be advisable to detail it, is before him, when he will find that the upper deck will supply, and at the right place too, the strength that he thinks is wanting. His defence, however, of the wave line theory will at any time be welcome, but I would remind him that in the comparative estimate made by me of the work done under each line, their common datum for calculation, (distance and angle being of course alike) was the point where the lines respectively begin to merge into the line of the ship's side, beyond which point, towards the midship section, the work done is nearly the same for each, and would be quite, only that there is a contrary flexure with the hollow line, which necessitates a greater convexity in the softening off than with the straight line.

Benjamin Cheverton.

Gossip.

William Templeton, Esq., the author of the "The Operative Mechanic's Workshop Companion," has just published a work entitled "The Engineer's, Millwright's, and Machinist's, Practical Assistant," being a collection of valuable tables, data, &c. Messrs. Lockwood, of Stationers' Hall Court, are the publishers.

An account of a new steam propeller, both curious and important, comes from Antwerp, describing the performance on the Scheldt on Tuesday of a newly invented steam craft propelled with perfect ease, and amenable to the most accurate guidance, while dispensing altogether with the comparatively cumbrous mechanism of either paddle wheel or screw. The motive power is simply a central pump forcing a continuous stream into two lateral tubes, the rapid backward gush from which propinges the barque, and is not liable to the entangling or disarrangement incidental to both the other systems of propulsion. The dockyard of MM. Cockerill has launched this specimen from a working model of Herr Seidel, and it is to ply forthwith on the Meuse, and between Liege and Seraign.

The terra-cotta pavements of the New Westminster Bridge, edged with Peterhead granite, and kerbed by cast-iron, are quite experimental, and we must plead guilty to some doubts as to their successful resistance of wear and tear. Time only will resolve them. The parapets of the structure are too low by a foot, and are unpleasantly suggestive of suicide, murder, and accident. This matter will have to be attended to beyond question, for although the view of the Houses of Parliament and the river is made more extensive and agreeable by the lowness of the parapet, yet the lives of Her Majesty's lieges must not be jeopardized to obtain it. A considerable amount of vibration is discernible at the crown of each arch during the passage of vehicles, and if there be an error in the construction of the bridge, it is in the economy of materials used.

On Wednesday last the petition of Mr. Alfred Vincent Newton for the prolongation of letters patent for certain improvements in dressing or cleaning grain, and in separating extraneous matters therefrom, was heard before the Judicial Committee of the Privy Council, and dismissed, with costs. Mr. Welsby appeared, on behalf of the Attorney-General, for the Crown; Mr. Grove, Q.C., and Mr. Macrory were for the petitioner.

The New Monitors.—Regarding the six new Monitors now in course of construction, the *Albany Courier* says:—"The new vessels are larger and far more powerful than the Monitor, but the principle of their construction is the same. The turrets are 21 feet in diameter and 11 inches thick—which is 3 inches thicker than the Monitor's. The armour plates are 6 inches thick. Each vessel is to be armed with two 15-inch guns, which is 4 inches larger than those of the Monitor. Their speed will be 10 miles per hour. The plates are being rolled in Maryland and Pennsylvania. All the rest of the iron for frames, fastenings, &c., amounting to several thousand tons, is being made by Corning, Winslow and Co., and the Rensselaer Iron Company, at their works in Troy. Four of the vessels are to be completed by the 1st of August, and two by the 1st of September. Some 2,800 men are at work upon these six vessels, and it is confidently believed by the contractors that they will have them completed within the stipulated time. If so, it will probably challenge the world for a parallel in mechanical achievement. An error exists in the popular mind as to the sea-going properties of these vessels—it being generally supposed that they are unsuited to outside service. It was demonstrated by the run of the Monitor from New York to Hampton Roads that she is as stanch and safe as the best modelled ship. The new vessels will be equally safe, and well adapted to service at sea."

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgment:—

Steam Engines, &c., 3120, 3123, 3126, 3173.

Boilers and their Furnaces, &c., *None.*

Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 3133, 3149, 3157.

Ships and Boats, including their fittings, 3129, 3130, 3132, 3182, 3187, 3194.

Cultivation of the Soil, including agricultural and horticultural implements and machines, *None.*

Food and Beverages, including apparatus for preparing food for men and animals, 3118, 3127, 3139.

Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 3122, 3131, 3136, 3151, 3153, 3155, 3162, 3165, 3174, 3181, 3183, 3192, 3193.

Buildings and Building Materials, including sewers, drain-pipes, brick and tile machines, &c. *None.*

Lighting, Heating, and Ventilating, 3124.

Furniture and Apparel, including household utensils time-keepers, jewellery, musical instruments, &c., 3121, 3134, 3145, 3158, 3159, 3160, 3161, 3172, 3176, 3189.

Metals, including apparatus for their manufacture, 3142, 3150, 3186.

Chemistry and Photography, 3147.

Electrical Apparatus, 3170.

Warfare, 3119, 3154, 3166.

Letter-Press Printing, &c., *None.*

Miscellaneous, 3125, 3128, 3135, 3137, 3138, 3140, 3141, 3143, 3144, 3146, 3148, 3152, 3163, 3164, 3167, 3168, 3169, 3171, 3175, 3177, 3180, 3184, 3185, 3191.

3118. A. Tonnar. *An apparatus for the drying and cleansing of malt, as well as any other species of grain and seed intended for brewing, distilling, and agricultural purposes.* Dated Dec. 12, 1861.

This invention consists in a peculiar method of employing centrifugal force for the combined purposes of putting the grain in motion, and for dividing and separatig from it the waste, for the distribution of the heat, for clearing away the damp air, and for the ventilation and sifting of the malt. *Patent completed.*

3119. J. W. Scott. *Improvements in wads for fire-arms.* Dated Dec. 12, 1861.

This invention consists in the manufacture of a compound wad, or wad and valve of leather or other suitable material, the valve part of which will yield and allow of easy insertion and ramming home of the charge, but which upon the discharge of the arm will be expanded and forced into contact with the whole circumference of the bore, and not only offer the necessary resistance to the explosive gases, but at the same time cleanse the barrel. The most simple form of compound wad and valve, and that which the patentee prefers, consists of a cup of compressed butt leather of or about the same circumference as that of the bore of the arm in which it is to be used; the edges of this wad may be toothed or plain, and instead of its being in the form of a cup, it may be a plain disc, and of any suitable material. To this wad, and preferably at the centre only, he attaches by a rivet, pin, or stud, or by glue or cement, a leather valve, rather larger in circumference than the bore. This valve, when the compound wad is inserted in the barrel, is placed uppermost. He sometimes forms this compound wad by inserting in or fixing to the edge of the wad, whether cupped or not, a ring or annular valve of leather, cloth, or other suitable material. The invention also consists in forming wads of simple discs of leather or other suitable material with toothed edges. *Patent completed.*

3120. J. D. John. *Improvements in locomotive engines, parts of which improvements are also applicable to marine and stationary engines.* Dated Dec. 12, 1861.

This consists, 1, in a mode of transmitting motion from the pistons or piston rods of the steam cylinders to the driving wheels. For this purpose a self-acting lever clutch is adapted to the nave of the wheel, and when it is desired to transmit motion from the piston of the working cylinder to the driving wheel, this lever-clutch is made to bind on the axle and nave, and thereby attach them for the time being firmly together; but upon cutting off the steam from the working cylinders and thereby stopping the action of the pistons, the lever-clutch will be drawn back, and the driving wheel left free to move on the axle without the latter rotating, and keeping in motion the whole of the driving gear of the engine, as is now the case. The invention relates also to a mode of constructing the pistons of the working cylinders. The piston consists of a top and bottom disc or plate, the form of which may be permanently attached to the piston rod, and the other secured in its place by screw bolts or otherwise. Recesses are made in the inner surfaces of these plates or discs to receive coiled or convolute springs, like clock or watch-springs, which are made to act on the back of wedge-shaped pieces or blocks. Segmental packing pieces form the packing of the piston, and are kept thrust outwards by the wedge-shaped pieces, which, by bearing against the clock-springs behind, will give a considerable amount of elasticity to the packing. The top and bottom plates or discs of the pistons are secured together with the springs and segmental packing pieces between them by means of screw-bolts,

which may pass through the springs. The invention also consists in adapting to the backs of the slide-valves of steam-engines segmental or other suitably-formed packing pieces, which are kept up to the working face of the top plate of the valve by coiled or other springs. A convolute spring is also adapted to the lever of the safety-valve. *Patent completed.*

3121. H. BAILEY. ***An improved button or stud.*** Dated Dec. 12, 1861.

This consists in forming the button or stud in two parts similar to the two discs or the faces of ordinary studs, and in furnishing the interior surfaces of these discs with a male and female screw formed of metal, and fixed in the button or stud, so that by applying the two portions thereof, one each side of the garment, or other object to be secured, and by screwing them together through a small eyelet hole made therein, a perfect fastening will be obtained. *Patent abandoned.*

3122. R. ASHWORTH, G. SHEPHERD, J. CORMACK, and J. DEARDON. *Improvements in looms for weaving.* Dated Dec. 13, 1861.

This consists in dispensing with the roller known as the emery roller in front of the loom, and in bringing the cloth from the loom at any constant velocity agreeing with the number of picks, thereby making the cloth even and uniform in texture. *Patent abandoned.*

3123. S. B. HEWETT. *Improvements in the construction of boilers or generators for steam engines and other uses, applicable also to evaporators, and in pumps used therewith or otherwise used, some of which improvements in pumps are applicable to pistons and piston rods generally.* Dated Dec. 13, 1861.

This consists in the construction of boilers or steam generators with a number of cells, tubes, or boxes, so as mutually to afford strength to stay each other, and to give strength to the whole structure of the boiler, &c. The improvements in pumps comprise, among other features, the constructing of a piston in two parts, to the upper of which is connected a tube enclosing the ordinary piston rod, the piston rod being connected to the lower, both tube and rod being connected to a cross head at the top, so as to admit of the tube or rod being turned, and the parts of the piston respectively connected thereto being also turned, thereby moving the intermediate packing onwards, and tightening the packing of the piston; the under side of the upper plate of the piston is formed with bevilled teeth or edges, gearing into bevilled pinions or pauls, and ratchet wheels connected to screws and nuts, which act so as to expand the metallic or other packing. The invention also consists in a mode of tightening the packing; also in using a suction pipe, with a worm rose inserted in it to prevent choking; also in the adaptation and application of a two throw crank, with its connections, as described. *Patent completed.*

3124 W. BELL. *Improvements in kitcheners or cooking ranges.* Dated Dec. 13, 1861.

The patentee claims, 1, making the bottom grate in two parts, namely, of a frame to be built into the brick work, and a perforated plate or set of grate bars to be dropped or placed in the said fixed frame. 2. Making the false or contracting grate bottom with a projection at its back, so as to make it fit against the back of the fireplace, and prevent the fire falling at the back of the said false or contracting grate bottom into the ashpit or pan of the grate. 3. A ventilator consisting of an iron box situated at the back and on the top of the oven, and extending the whole or nearly the whole width of the oven, and communicating therewith by a series of openings, or one large opening. Lastly, the new latch for the oven doors of kitcheners constructed, as described. *Patent completed.*

3125. F. BRAMPTON.—*An improvement or improvements in the manufacture of the middle joints of measuring rules.* Dated Dec. 13, 1861.

In the middle joints of measuring rules, as ordinarily constructed, one side of the joint consists of a circular disc of brass, and a flap or plate of about one-half the thickness of the said disc. The whole of the said side is made from one piece of sheet metal of the thickness of the disc, the thickness of the side being reduced by turning or cutting away the metal at that part. This invention consists in making the said side of sheet metal of the thickness of the flap or plate, and making the disc in the following manner:—The blank is cut in the usual way, excepting that the disc part is a little larger than the finished disc is required to be. By means of raising tools the edge of the disc is raised into a plain at right angles to the other part, and there is thus formed a rim of a depth somewhat greater than the thickness required in the finished disc. A disc of zinc or iron is placed within the said rim, and fixed therein by closing tools. The side is finished in the ordinary way, and the joint made therewith has the appearance in the finished rule of a joint made wholly of brass. *Patent abandoned.*

3126. H. J. OLDING. *Improvements in the mode of, and apparatus for feeding steam boilers, also in apparatus for supplying fluids for other purposes, and in apparatus for raising fluids.* Dated Dec. 13, 1861.

The patentee claims, 1, the mode of arranging, combining, and applying apparatus for feeding steam boilers, according to which a chamber and pipes or passage are so arranged and combined with each other and the boiler, that the feed or supply of fluid to the boiler is self-acting, or self-regulating, as described. 2. The improved flat valve described, in so far as regards the arranging and combining of an annular float with stem and valve plate, as described. 3. The impinging plate-valve described, in so far as regards the combining of a valve plate with a plate of broader surface, as described. 4. The arranging and combining of the impinging plate-valve described with the spring, with angular bend or projection, as described. 5. The arrangement and combination of apparatus substantially in manner described, for feeding or supplying fluids to vessels other than steam boilers. 6. Arranging and combining apparatus for raising fluids substantially, as described. *Patent completed.*

3127. C. E. B. de BEAULIEU. *Improvements in the manufacture of spirituous liquors, and in apparatus employed therein.* Dated Dec. 13, 1861.

Here the object is the distribution of spirituous liquors, so as to prevent their receiving that empyreumatic flavour which always accompanies them when distilled in the usual way. The invention consists in distilling such spirituous liqours in a more or less perfect vacuum, by certain apparatus whereby the heat required for the volatilization of the alcohol from the fermented substance is reduced to so low a degree as to prevent the simultaneous volatilization of the empyreumatic oils, which are generally degenerated by the action of a greater heat upon the fermented matter. *Patent completed.*

3128. G. BIRD. ***An improved lubricating grease.*** Dated Dec. 13, 1861.

This consists in taking tar oil, or oil such as is obtained in the process of distilling tar, and first removing from it the more volatile parts by distillation. The heavy oil thus obtained may be used for lubricating, or there may be mixed with it a quantity of gelatinous matter, such as size, for the purpose of giving a body, and for a similar purpose cream of lime may also be used. *Patent abandoned.*

3129. J. W. FRIEND. *Improvements in apparatus for registering the depth and flow of liquids, and the distances run by ships at sea.* Dated Dec. 13, 1861.

This consists of a fan or paddle-wheel, mounted upon spindle bearings (within a suitable case), furnished with water-ways for conducting the fluid to the floats or paddles; in connection with revolving graduated wheel or dial-plates, through the intervention of tangent tooth and pinion gear, so arranged that, upon the fan or paddle-wheel being actuated by the passage of the water through the instrument, the graduated wheel or dial-plates will be caused to register results corresponding thereto for the purpose of indicating the depth of water at sea, the speed or distance run by ships or other vessels, or the amount of fluid otherwise passed through the apparatus, the apparatus when used as a log being curved and weighted, so as to maintain its proper position in the water, and is also provided with side wings for keeping the same constantly submerged. *Patent completed.*

3130. T. WALKER. *Improvements in means or apparatus for indicating the speed of vessels, and for taking soundings.* Dated Dec. 13, 1861.

For indicating the speed of vessels the patentee applies inclined or oblique vanes upon a tube which is capable of freely rotating upon a central spindle or axis, when acted upon by passing through the water. The fore end of the axis is provided with a protector, which he prefers to be of a conical form adapted to prevent the water pressing upon the end of the tube carrying the vanes, and thereby causing friction, which would impede the proper working of that tube by the action of the water on its oblique or inclined vanes. The wheel work for registering the rotation of the vanes is carried by a frame, which, like the protector, does not revolve, and is enclosed within the tube, or within the protector, or it is carried by some other part of the apparatus, which does not revolve. Motion is given to the registering wheelwork by a wheel attached to the tube of the rotators acting on a pinion, or by a stud on the tube of the rotators acting on the arms of a wheel affixed to a worm or pinion, giving motion to the first of the series of wheels, or by other means. A slide or other cover encloses the dials, which slide is capable of easy removal to see the distance run without removing the wheelwork. For taking soundings, the apparatus is similarly arranged, but with a weight to assist its descent, and the dials are formed to indicate fathoms and parts of fathoms, in place of miles and part of miles. *Patent completed.*

3131. T. B. GIBSON. *A new or improved ornamental fabric.* Dated Dec. 13, 1861.

This relates to the production of a new ornamental fabric, and consists in applying coloured designs, either by the aid of block or cylinder printing, to harness curtains, and other figured fabrics of that class. *Patent completed.*

3132. S. PADLEY. *Improvements in paddle-wheels.* Dated Dec. 13, 1861.

Here the floats are disposed in any suitable way independently around and between the concentric rims of the paddle-wheels, which are keyed fast on the paddle shaft in the usual way. Each float has an axis or shaft which passes through, and is free to vibrate in, the rims of the wheels; the axis of each of the floats is, on the exterior face of the inner rim of the wheels, formed as a crank, or has a half crank fixed thereon, the pin of which is received by and rotates in a corresponding hole or bush formed in the rim or periphery of a disc placed parallel with the wheels, but eccentric to the axis thereof, and capable of adjustment thereon, which eccentric movement is used in causing the floats to enter and leave the water, without the complication of mechanism involved in the various contrivances at present in use for producing the reefing or feathering motion in floats which have not a vibratory action, such as is due to their being mounted upon a horizontal shaft or axis according to the present invention. *Patent abandoned.*

3133. P. QUANTIN. *Manufacturing moulded earthen or stoneware cross sleepers for superseding wooden ones in the construction of railways.* Dated Dec. 13, 1861.

Here the patentee manufactures moulded earthen or stoneware cross sleepers, of any required shape or size, and moulded either hollow or solid, and to suit the various descriptions of rails which may be used. He supports the rails upon such cross sleepers either by the interposition of wooden or other bed pieces, or without their intervention, and they be keyed or fastened in any of the ordinary ways. Instead of using clay alone he mixes it and tempers it with any other suitable material, the better to adapt it to the purpose for which it is intended to be used. The cross sleepers of this invention can be made of various sizes and shapes to suit the rails of different descriptions; they are composed of two blocks of earthen or stoneware moulded to a uniform shape, which two blocks are united together by an iron rod of suitable strength. Thicknesses of felt, or any other compressible material, are inserted betwixt the blocks of earthenware and connecting iron rod or bar; the chairs are placed over the rod or bar, and the whole is bolted fast together to form cross sleepers ready to receive the rails. *Patent completed.*

3134. T. CABOURG. *Improvements in screwing leather for the manufacture of shoes, and for other purposes.* Dated Dec. 13, 1861.

The object here is the construction of a machine which will form a thread upon a continuous length of brass wire, and at the same time cause it to penetrate by screwing into any portion of leather, or such like material, so as to unite them in one. *Patent abandoned.*

3135. A. V. NEWTON. *An improved arrangement of fire-escape.* (A communication.) Dated Dec. 13, 1861.

This consists in the use of a flexible or chain ladder applied to a building so that it may be folded in a tilting box, and in case of fire be released in a moment either by an inmate of the dwelling or a person at the outside, and the ladder allowed to descend to the earth, and form a ready means of escape. Also in combining with the flexible or chain ladder an alarm, so arranged that it will be sounded simultaneously with the liberating of the ladder. *Patent completed.*

3136. J. HETHERINGTON, T. WEBB, and J. CRAIG. *Improvements in machinery or apparatus for spinning and doubling cotton and other fibrous materials.* Dated Dec. 13, 1861.

This relates, 1, to the spindles of spinning and doubling machines which have no top bearings, and consists in forming the top of the spindle as a screw, for the purpose of holding and conducting the thread to the flyer. As a matter of construction the patentees form the screw of a separate piece, and adapt it to the spindle. 2. The invention consists in the application of a flexible bush to the copping rail. 3. In the use of a tube fixed to the bolster rail for supporting the spindle, and which tube is traversed by the copping rail. 4. In a method of throwing the wheels of spinning and doubling spindles out of gear. *Patent completed.*

3137. H. APPLEBY and H. HARRISON. *Improvements in machinery for boring wood and other materials used for the manufacture of brooms and brushes.* Dated Dec. 13, 1861.

Here, in order that numerous holes may be simultaneously bored in a piece of wood, to receive tufts or bristles in the manufacture of brooms and brushes, a number of suitable drills or boring tools are employed, each mounted separately in a socket or holder on the end of a stem, which is so formed in parts connected by universal joints as to admit of a part of a stem being at an angle to the plane in which the drill or boring tool carried thereby works. At that end of the stem where the boring tool is applied a perforated plate is stationed, having in it a number of holes corresponding with the holes desired to be bored in the piece of wood, and in each of these holes there is a socket for a boring tool, and each socket has motion communicated to it by a stem constructed as above described. From this plate the stems diverge from one another and get further and further apart, and they pass through sockets which turn in holes in another plate. To the plate last mentioned a lever is applied, or other provision is made for moving it forward, together with the stems of the boring tools, so as to advance the boring tools into the wood held to the points of the boring tools. The back ends of the stems are supported in any suitable bearings, and each stem has on it a pulley or drum to receive a band or strap driven by a cylinder which is put in motion by a steam engine or other power. *Patent completed.*

3138. T. K. ADKINS, and J. BOUTHRON. *Improvements in the manufacture of starch, and in apparatus employed therein.* Dated Dec. 13, 1861.

Here the inventors take flour and make it into dough by kneading it with water; the dough is placed in a trough or vessel in which are surfaces having points or spikes upon them, and these surfaces, having a vibratory or other motion, continually perforate the dough. Streams of water run over the dough during this operation, and wash away the starch from it. The water with the starch escapes from the trough or vessel through holes covered with wire gauze or finely perforated metal; it runs into a vat where the starch is deposited. The supernatant water is run off, and the starch again mixed up with a small quantity of water, to which acetic acid is added; this mixture is allowed to ferment, a process which removes the impurities from the starch; a scum rises to the surface, and is skimmed off, when the purification is complete. The starch is made for sale in the usual way. *Patent abandoned.*

3139. J. KELLY. *Improvements in the treatment of milk for the manufacture of butter, and in apparatus for the same.* Dated Dec. 13, 1861.

This relates to making butter by a dairy range. The milk is preserved in milk vessels of glass from the time it is taken from the cows till the butter is made. The process of churning (in the lever churn, which is to be in connection with the dairy range) will occupy only a few minutes. *Patent abandoned.*

3140. R. A. BROOMAN. *Improvements in, and apparatus for, the production and application of motive power.* (A communication.) Dated Dec. 13, 1861.

This invention is based upon what the inventor terms the spontaneous transformation of a liquid into an elastic fluid, or, in other words, into dry steam at the moment of generation, which he terms spheroidal steam. The invention consists, 1, in the employment of a steam chamber floating in or on a metallic bath, serving in case of need for regulating the supply by the quantity of non-vapourized liquid it is capable of containing. 2. In the employment of a metallic bath of tin, lead, or other fusible metals, at the bottom of a generator for causing the spheroidal vapourization in the floating chamber; the bath renders the bottom of the generator inoxidizable, and prevents it becoming perforated or pierced, a result often produced by the sudden and incessant effects of expansion and contraction. 3. In the general arrangement of the feeding apparatus. 4. In the construction and arrangement of a pyrometric whistle. 5. In the construction of heat indicators for showing the temperature in the generators and condenser,

and for registering and indicating the draught in the chimney. 6. In the construction of a tubular supply generator. 7. In the construction of a tubular condenser. *Patent completed.*

3141. R. A. Brooman. *Improvements in blowers or apparatuses for superheating steam and other gases, and for projecting them combined with atmospheric air upon ignited combustible matter.* (A communication.) Dated Dec. 13, 1861.

This invention relates to the generation and employment of dry and superheated steam at a temperature of about 390° Fahr., or of a gas, fixed or not, the pressure of which shall be equal to what may be necessary for the particular application for which it is to be used. This steam or gas is caused to escape from an orifice, by virtue of its compression, into another orifice, calculated according to the quantity of air required in a given time. The mixture of steam, or gas, and air, is projected upon ignited combustible matter. There is then produced the phenomenon of double decomposition, the air yields its oxygen to the combustible matter to assist its combustion, and the steam already divided will become decomposed into oxygen and hydrogen, so as to produce the highest combustion. The apparatus invented for carrying the invention into effect is not described apart from the drawings. *Patent completed.*

3142. E. C. B. de Beaullieu. *Improvements in apparatus for extracting gold dust from auriferous sands.* Dated Dec. 14, 1861.

The patentee claims, 1, the arrangement by which the peculiar duplex vibrating motion is imparted to cylindrical sieves, as described with reference to the drawings. 2. The construction of apparatus for separating the gold dust from auriferous sands, in which the sand is caused to pass slowly along on the surface of a bed of mercury, to which a rapid vibrating or undulating motion is imparted, which motion being communicated to the sand causes the gold dust contained in the same to be separated from it by reason of it greater specific gravity, and to be precipitated into the bed of mercury, substantially as described. *Patent completed.*

3143. J. E. Duyck. *Improvements in the expression of oil from cake and seeds, and in apparatus employed therein.* Dated Dec. 14, 1861.

This invention consists in constructing plates or frames, which are to be fixed to leather or other suitable holders, of a series of transverse strips or bars bolted or rivetted on one side to the leather. These strips are united to two longitudinal tapering side plates, formed so as to admit the edges of the holder between the two thicknesses of the plates, and with channels open or closed beyond the distance to which the edges of the holder extend; there is also space between the leather and the side plates for the oil to run through and enter the channels. The patentee also employs between every pair of plates fixed to holders as aforesaid a naked plate, that is to say, a plate formed with transverse bars, and with conical channelled sides, as before described. The invention also consists in forming grooves or channels in the sides of the box or press, in which the material is placed to receive its pressure. He then places against the grooved sides a perforated plate, one on each side, the perforations in which communicate with or lead into the grooves, and thus escape is provided at the sides of the box or press for the outlet of such oil as may be expressed. *Patent completed.*

3144. F. Kohn. *An improved mode of copying writings, drawings, prints, and similar objects.* Dated Dec. 14, 1861.

This consists in passing an electric current through a great number of sheets of paper, or other suitable material, piled one upon another, and impregnated with substances capable of producing a coloured stain on the paper at any place where the electric current passes through the same. A substance of this kind is nitrate of silver dissolved in distilled water. *Patent abandoned.*

3145. C. McDougall and Joseph Crane. *Improvements in raising and supporting ladies' dresses.* Dated Dec. 14, 1861.

This consists in attaching to the ordinary clasps, hooks, or holders, a cord or band, and passing it through rings, eyes, swivels, or pulleys fixed and suspended to the belt which encircles the waist. The ends of the aforesaid cord or band are provided with knobs or tassels, which rest against the belt when the bottom of the dress is in its lowest position; but when the dress is required to be raised, the knobs or tassels are pulled so as to draw up or tighten the cord or band and raise the holders, and with them the bottom of the dress. *Patent abandoned.*

3146. W. R. Rogers. *An improved mode of constructing dovetail joints.* Dated Dec. 14, 1861.

The patentee claims inserting in the grooves of adjacent or contact surfaces metal or other keys for locking the parts together, as described. *Patent completed.*

3147. W. C. Debenham. *An improved plate holder for photographic purposes.* Dated Dec. 14, 1861.

This invention is not described apart from the drawings. *Patent abandoned.*

3148. W. Husband. *An improved water safety valve.* Dated Dec. 14, 1861.

This invention is not described apart from the drawings. *Patent completed.*

3149. J. H. Johnson. *Improvements in railway rolling stock.* (A communication.) Dated Dec. 14, 1861.

By this invention the passage of railway rolling stock round curves is facilitated, and the wear and tear of the rails and wheel tyres greatly reduced. It is proposed to fit one of the wheels upon the axle, so as to admit of its rotating freely thereon, the opposite wheel being fast in the axle. *Patent abandoned.*

3150. E. Cajoz. *Improvements in the treatment of pyrites for the manufacture of iron.* Dated Dec. 14, 1861.

Here the patentee mixes the residues of pyrites with other matters adapted to their proper fusion. The matters he uses are argillaceous earths, pulverized limestone or chalk, and he employs them conjointly or separately, according as their ascertained qualities are found favourable to the proper fusion of the pyritous residuum. *Patent completed.*

3151. J. Willis. *Improvements in the preparation of materials applicable to the manufacture of paper.* Dated Dec. 16, 1861.

This consists in the preparation of oatmeal seeds and sawdust, so as to adapt them for use as ingredients in the manufacture of paper, either separately or in combination. *Patent completed.*

3152. G. P. Vallas. *Improvements upon or additions to certain description of baths, with the object of rendering them available for use as trunks or boxes.* Dated Dec. 16, 1861.

This consists in adapting to hip and sitz baths; a removable lid or cover, and to such baths as have a rim or foot continued below the actual bottom of the bath, a fixed or removable bottom, whereby each description of bath may be used as a trunk or box. *Patent completed.*

3153. G. Davies. *Improvements in the manufacture of textile materials.* (A communication.) Dated Dec. 16, 1861.

This consists, 1, in the use for the manufacture of textile fibres of certain parts of the leaves and stalks of the plant known as Indian corn or maize. 2. In a process whereby the fibrous portions of such plant are reduced to a state in which they may be prepared, spun, and woven by the machines and processes ordinarily used for preparing, spinning, and weaving flax, hemp, &c. This process consists mainly in boiling the leaves and stalks in separate and suitable steam boilers or vessels. Sometimes it is necessary to add to the water a little lime or solution of soda. *Patent completed.*

3154. W. Bartram, and W. S. Harwood. *An improved apparatus for filling and ramming cartridges for breech-loading and other fire arms.* Dated Dec. 16, 1861.

This consists of a cylindrical tube of sufficient bore to receive the cartridge case, which is inserted at the lower end of the tube, the upper end of which is furnished with a cap screwed thereon, through which a cylindrical rammer is worked by hand or otherwise. The cylinder and rammer being in a vertical position, and the cartridge case having been inserted, the gunpowder is poured into the cylindrical rammer, which is funnel mouthed at the top, and forms both a rammer and feeder; the powder falls into the cartridge case, and a wad is then inserted through a slot in the cylinder above the cartridge case. The wad falls on to the powder in the case, and the rammer is then brought to bear upon the wad, so as to firmly fix it in its place on the top of the powder. The same process is then to be repeated with the shot. A spiral spring round the exterior of the rammer (to which one end of it is attached) serves to raise the rammer to its first position. The cylinder is furnished with a small slot or opening at its lowest part, so as to allow the wire in cartridges for breech-loading guns to pass through the cylinder, and still allow it to stand flat on the table or bench on which it is operated. *Patent completed.*

3155. D. Chalmers. *Improvements in looms for weaving, and in the manufacture of cloth therefrom.* Dated Dec. 14, 1861.

This invention is not described apart from the drawings. *Patent completed.*

3156. J. Aitken. *Improvements in supplying water to water-wheels.* Dated Dec. 16, 1861.

Here the patentee introduces a syphon between the wheel and the head or source of supply, so that the water from the head rises up the shorter leg of the syphon to the wheel. The water may be pumped or otherwise returned to the head or source of supply, where the shorter leg of the syphon is situated. *Patent completed.*

3157. W. G. Laws. *Improvements in railway point signals.* Dated Dec. 16, 1861.

This invention is not described apart from the drawings. *Patent completed.*

3158. C. Baumann. *Improvements in buttons.* Dated Dec. 16, 1861.

Here the button is so made that it may be attached to the fabric by a screw passing through the fabric from the back, and entering the stem of the button. The stem of the button is bored and tapped to receive the screw; there is a head formed on the screw, and a disc on the lower end of the stem of the button, and between these, when the button is fixed, the fabric is nipped. *Patent completed.*

3159. W. H. Tucker. *Improvements in locks.* Dated Dec. 17, 1861.

The specification of this invention is very voluminous, and cannot be quoted here at sufficient length for an intelligible abstract. *Patent completed.*

3160. J. W. Chalfont and D. Keys. *Improvements in winding up fusee watches and pocket chronometers, and setting their hands without keys.* Dated Dec. 17, 1861.

At the top or bottom of the axis of the fusee the inventors fix a wheel, into which acts another; attached to a ratchet runs a wheel in gear with a contrate wheel, the arbour of which goes through the pendant that may be turned by a small knob, which is also in action with a click spring; this spring is fastened in a box that is detained by another spring, so that when the wheel in action with the click is turned, it brings the click in action with the ratchet, and thereby the watch is wound up. When the detaining spring is pushed away by a piece projecting from the side of the case, it leaves the click free of the ratchet, at the same time taking an intermediate wheel into gear with the minute wheel, thereby enabling the hands to be set either way. *Patent abandoned.*

3161. J. B. Bunney and L. Wright. *Improvements in ornamenting metallic and non-metallic bedsteads and other articles made principally of metallic rods or tubes.* Dated Dec. 17, 1861.

This consists in casting on, or in casting and afterwards fixing on, the parts to be ornamented, ornaments of zinc, or other hard and cheap metal or metallic alloy, and afterwards coating the said ornaments with brass or silver, or painting, gilding, or japanning the said ornaments. The inventors effect the metallic coating by electro deposition. *Patent abandoned.*

3162. R. Shaw. *Certain improvements in carding engines.* Dated Dec. 17, 1861.

This consists in the use of an endless band or web of open wire work, lattice or woven fabric continuously traversing beneath the carding cylinders, and used as a creeper for conveying any loose cotton or other fibrous material falling from the cylinders whilst being carded back again to the "licker in." *Patent completed.*

3163. J. Dale. *Improvements in the manufacture of glue or size.* Dated Dec. 17, 1861.

Here the patentee takes tanners' refuse called "fleshings," and adds thereto muriatic acid; he then washes them, afterwards neutralizes any remaining acid, boils to separate the fatty matters, and obtains glue or size in the ordinary way. *Patent completed.*

3164. A. V. Newton. *Improved hoisting apparatus.* (A communication.) Dated Dec. 17, 1861.

This consists in the use of two pulleys of different diameters, and an endless chain, band, or rope applied to the pulleys, and arranged substantially as described, whereby the desired end is attained. The invention is not described apart from the drawings. *Patent completed.*

3165. J. Platt and W. Richardson. *Improvements in machinery or apparatus commonly called "gins" for cleaning cotton from seeds.* Dated Dec. 17, 1861.

This relates, 1, to apparatus which acts as a transferring comb for conveying the materials to the rollers in a prepared condition after the manner described in the specification of a patent granted to the present patentee on the 5th June, 1861 (No. 1439), and also to other apparatus used for agitating the material, or pushing it forward towards the rollers, and consists in so forming such apparatus that it shall yield to any undue resistance. Thus, if a connecting rod be employed, they cause it to act through the agency of springs, which may be caused to collapse by such resistance as aforesaid. 2. The invention consists in the adaptation of weights to the rollers of roller gins, for causing the one to bear against the other. *Patent completed.*

3166. R. Scott. *An improved method of rifling or grooving the barrels of fire-arms and ordnance.* Dated Dec. 18, 1861.

This consists in cutting the longitudinal spiral grooves along the interior surface of the barrels of rifles and ordnance, so as to present the smoothest possible surface to the projectile, in order to approximate as closely as practical to the cylindrical smooth bore; but at the same time giving sufficient from the cylindrical form to insure the projectile following the curved rim of the grooves without stripping. The patentee effects this object by giving to the grooves the cross sectional form of an arc of a circle, the radius of the arc being rather less than that of the interior surface of the barrel previous to grooving; the grooves when cut occupy the whole of the interior surface of the barrel, and the sides of the grooves intersect each other as they meet the interior cylindrical surface of the barrel. These points of intersection thus form raised angular bands running spirally down the barrel, and are the only lines of the interior surface of the barrel not cut away in the process of rifling. *Patent completed.*

3167. S. Sheppard. *A new or improved tap or stop-cock.* Dated Dec. 18, 1861.

This invention is not described apart from the drawings. *Patent completed.*

3168. J. Perrin. *An improved equilibrium valve.* Dated Dec. 18, 1861.

This relates to that description of valve used for diminishing the pressure of steam from high to low, or when used as a throttle-valve for regulating the supply to the cylinder. The inventor fixes two valves of the same diameter upon one spindle, and also a piston equal to one square inch of area, and causes the top of the spindle to be weighted with weights, each weight indicating 1lb. pressure of steam. The piston works in a cylinder, and is acted upon by the steam, so as to balance the weights according to the pressure, and as the valves are of equal diameters this arrangement is perfectly equilibrium. The valves are webbed and work through holes, and are bevilled to allow the steam to pass freely, and thereby prevent the shocks from sudden changes of pressure which generally occur with the ordinary flat valve. *Patent abandoned.*

3169. M. Cartwright. *Improvements in the manufacture of bels or palates for the reception of artificial teeth.* Dated Dec. 18, 1861.

This consists in a method of manufacturing models used in preparing plates or pieces for artificial teeth of vulcanite, ebonite, or hardened rubber, alone, or combined with soft vulcanized rubber. Also, in combining or amalgamating india rubber and gutta percha with metals, for the manufacture of artificial teeth or pieces, and for other purposes. *Patent abandoned.*

3170. W. Dicey. *Improvements in submarine electric telegraph cables.* Dated Dec. 18, 1861.

This refers to the covering or protecting of the core, and consists in effecting, or constructing the covering by ribbons or strips of metal applied or laid upon the core in a longitudinal direction, not perfectly in line therewith, but with a small amount of uniformly spiral twist around the core, and with an edge of each ribbon or strip overlapping one edge of the next or adjoining ribbon or strip. *Patent abandoned.*

3171. A. Petersen. *An improved system of drainage and irrigation for meadow and other land.* Dated Dec. 18, 1861.

Here from the head or top of the meadow the main drain is laid in the direction towards the lowest part of the meadow, at a distance of four to five feet from the surface. From this main drain side drains branch off at right angles with the main drain; and where required, these side drains have again their branches. These side drains are laid with a slight fall towards the main drain. At each place where a side drain enters into the main drain a shaft or pit is formed, reaching from about eighteen inches above the surface of the ground to the bottom of the main drain, and into the sides of which shaft the mouths of both the main drain and the side drains open. On the side towards the

off-flow, the main drain is fitted with a valve or sluice, which can be shut or operated as the case may require. By means of these sluices the water can be discharged or admitted and retained in any of the side drains, and the water raised to and kept at any desirable level between the bed of the closed sluice or main drain and the surface of the ground. Shallow regulating ditches are formed on the surface of the ground immediately over the side drains, which can be filled and made to run over the surface of the meadow, or in which the surplus surface water may collect and discharge itself into the shafts, which are for this purpose provided with openings or grates at the sides above the surface of the ground. *Patent abandoned.*

3172. M. HAUFF. *Improvements in the manufacture of boxes and cases.* Dated Dec. 18, 1861.

This relates to the manufacture of boxes and cases of what is termed leather cloth, and of that kind used in the manufacture of cap peaks in combination with mountings or framings of metal, gutta-percha, &c. The inventor forms the body, bottom, and top of the cloth material, and connects the bottom to the body by a metal or other ring or mounting. The bottom drops into the mounting, and rests on an internal flange, while the body of the box is tightly inserted above it, and held and fixed by the vertical part of the mounting. The upper end of the body may be stiffened by a binding or lip of metal or other material. The top or cover is furnished with a mounting similar to the bottom one in which the cloth material is held, the mounting being fitted to the lip or upper part of the body to slip on and off with the hold and facility required. *Patent abandoned.*

3173. J. RIDDINGTON. *Improved condensing apparatus or steam-engines.* (A communication.) Dated Dec. 18, 1861.

This is designed to dispense with the cold-water pump commonly used in condensing engines, and to produce purer water for feeding the boiler by condensing apparatus of the following construction :—The patentee uses a hollow cylinder, to the lower end of which a tube is fixed, and its other end connected to an air-pump. Beneath the piston thereof, within the aforesaid hollow vessel, are fixed two other vessels of smaller diameter ; the lower end of one vessel communicates by an outlet pipe fitted with a cock, with a well or other water supply, and the upper end of this vessel communicates with a perforated hollow chamber formed around the upper part of the second vessel, the lower end whereof extends to the feed-pump of the boiler beneath the piston thereof. The upper end of the hollow cylinder aforesaid is fitted with a dome-shape cover, to the top of which a bent pipe is fixed, the said pipe being used to conduct the steam from the cylinder of the engine into the condenser, the condensed water passing into a reservoir by a cock fitted in a branch of the said bent pipe. The effect is as follows :—The air-pump being put in motion forms a vacuum in the condenser, and causes water to enter therein, and pass through the perforations in the vessel therein, and coming into contact with the steam from the cylinder of the engine will condense the same. *Patent completed.*

3174. J. THIEBAUT. *Improvements in the ornamentation of textile fabrics.* Dated Dec. 18, 1861.

This refers to the ornamentation of textile fabrics such as muslin, net, silk, velvet, cloth, &c., and consists in printing or producing thereon ornamental designs, or devices by the granulated mineral or sparkling metallic substance known as steel dust. *Patent abandoned.*

3175. C. E. SYMONDS. *Improvements in the treatment and application to various useful purposes of certain organic compounds.* Dated Dec. 18, 1861.

This consists in the treatment and application to any useful purposes of any light spirituous liquid that distils over at a temperature of under the boiling point of water, having a specific gravity not exceeding 0·850, obtained from coal, peat, bitumen, bituminous schists, and other bituminous substances, petroleum, rangoon, tar, crude paraffine oils, rock or earth oils, &c. The patentee prefers to purify this light spirit having the aforesaid properties. *Patent abandoned.*

3176. E. PACE. *An improved lath for Venetian blinds.* Dated Dec. 18, 1861.

This consists in forming each separate lath of two leaves of wood (produced by a wood-slicing machine) glued or cemented together. By these means warping is prevented, after planing is avoided, and saving in wood is effected. *Patent abandoned.*

3177. J. M. H. A. TAURINES. *Improved mode of constructing balances, weighbridges, and other weighing machines.* Dated Dec. 18, 1861.

This invention is not described apart from the drawings. *Patent completed.*

3178. J. BANNEHR. *Improvements in apparatus for desiccating seeds, grain, and other articles.* Dated Dec. 18, 1861.

Here the patentee provides a cylinder, which he places horizontally, and which is furnished with longitudinal ledges or shelves in the interior, and such cylinder he causes to rotate round a hollow shaft passing through the entire length of the cylinder, this shaft is perforated, but stopped or plugged in the interior towards its outlet end. In connection with the hollow shaft he applies a fan or fans, or other apparatus to cause a current of air (either at its natural temperature or heated) to pass into and through such hollow shaft, and to be discharged through the perforations in numerous streams, to impinge on and take up the moisture from such matter as may be placed within the cylinder. The moistened air passes out either into and through a condenser, or into a chimney shaft. He provides the cylinder with suitable openings for loading and unloading, and he either closes up one or both ends of such cylinder, or not, providing, however, for the escape of moistened air. *Patent completed.*

3179. C. PONTIFEX. *Improvements in refrigerators for cooling worts and other liquors.* Dated Dec. 18, 1861.

This consists in an arrangement of refrigerators, having a number of pipes laid side by side, and over each other, in each of the troughs or channels, through which the wort or other liquor travels. The ends of each set of pipes in each trough are fixed into a metal box, so arranged that, by removing a cover on the box, the inside of the box may be easily got at to be cleaned or repaired, and any one or more of the pipes can thus be readily removed or exchanged if desired. The cooling liquid, or the liquor to be cooled, as the case may be, gets thoroughly mixed in these boxes after passing out of one set of pipes, and before entering another. This arrangement may, however, be modified. Another part of the invention consists in bringing the cold liquor into more active contact with the pipes containing the wort or other liquor to be cooled, when the apparatus is thus arranged to act. For this purpose the patentee prefers to construct the hinge used for lifting the frame with slots in the plates forming one portion of the hinge, and in the side of the refrigerator back he places rollers so arranged that the frame carrying the pipes is free to move sideways on these rollers to any extent desired. He actuates this frame by connecting rods working from eccentrics or cranks, which he prefers to place on the shaft that carries the drum employed to lift the frame when out of use. *Patent completed.*

3180. W BETTS. *Improvements in the manufacture of coverings for the ends of cigars.* Dated Dec. 19, 1861.

Here it is proposed to manufacture these coverings in a stamping machine, constructed on the principle of the bottle capsule machines, but with such modifications that great rapidity of manufacture may be combined with little or no waste of material, so that the cost of manufacture may be reduced to a minimum. The coverings are stamped out of discs of soft metal, which may be perforated in the centre before being introduced to the punches and dies, or perforated during the process of stamping. *Patent completed.*

3181. T. BOURNE. *Improvements in cotton gins.* (A communication.) Dated Dec. 19, 1861.

This is designed to clean all varieties of cotton by separating the seed from the fibre without breaking the seed or injury to the staple. The patentee uses a roller in combination with an adjustable stripping plate, an adjustable breast-plate, a screen or grating formed of rods, a chute, a feed-board, a stationary brush, and cams and springs. *Patent completed.*

3182. W. TATE. *Improvements in armour, and in making and applying the same, for protecting wood and iron ships of war and batteries.* Dated Dec. 19, 1861.

This consists in the use of, and improvements in the manufacture and mode of applying iron and steel wire (galvanized or ungalvanized) rope, stranded belts (of small and of large sized wires), round or flat, applied singly in belts of iron or steel, or intermixed as one belt, being by preference one-third steel and two-thirds iron wire, as armour for wood and iron ships of war and batteries, in place of iron plates, or in conjunction with iron plates. The iron and steel flat belts should be manufactured to suit the full length of the ship or batteries, from, for instance, 50 feet up to 600 feet, if required, and from 4 inches to 30 inches broad, and from half an inch to two inches in thickness (more or less). These belts should be laid on in tiers, as may be required, and when the proper strength has been obtained, then planked over with 3-inch teak planking, and if required, bolted through all, and then covered neatly (over all) with half-inch steel plates, 24 inches broad. *Patent completed.*

3183. E. STOTT. *Improvements used in apparatus for collecting and removing the waste and dirt which occurs in the process of spinning cotton and other fibrous materials.* Dated Dec. 19, 1861.

The first of these improvements consists in constructing and arranging the brackets so that the scavenger roller can yield and give way when any extraordinary pressure is opposed to it, and so prevent damage and breakage of the machinery. 2. In the application of mechanism by which the brackets (and consequently the scavenger roller) are raised so as to be entirely clear of the carriage boards during the running in of the carriages ; but on the carriage drawing out, the scavenger roller falls on to the carriage boards, and collects and removes the waste and the dirt as the carriage recedes from the roller beam. The third improvement relates to the application of certain mechanism, by which the scavenger roller not only cleanses the carriage boards from waste and dirt, but also cleanses the waste and dirt from the stands and front of the roller beam. *Patent completed.*

3184. J. H. G. WELLS. *Improvements in pumping elastic fluids.* Dated Dec. 19, 1861.

This invention is not described apart from the drawings. *Patent completed.*

3185. A. TRENILLE and F. X. TRAXLER. *A safety paper intended to prevent any forgery and fabrication of shares, bank notes, cheques, bills of exchange, stamped paper, postage stamps, &c., and preventing, likewise, all alterations and falsifications of public and private writs ; the same process being also applicable to the manufacturing of playing cards and other cards, or tickets made use of by railway companies and other administrations, public or private.* (A communication.) Dated Dec. 19, 1861.

This paper consists of a single sheet formed of several layers of pulp superposed of different nature and lines, according to requirements, and it may be made as resisting and strong as required for the various purposes. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated April 17, 1862.

1131. H. Gallagher, Bermondsey, manufacturer. Improvements in overalls, leggings, or in overboots.

Dated May 5, 1862.

1329. T. Wilson, Birmingham, engineer and gun manufacturer. Improvements in the manufacture of armour plates for ships of war and batteries, and in fastening or securing armour plates to ships of war and batteries.

Dated May 26, 1862.

1572. W. Clark, 53 Chancery-lane, engineer. Improvements in the manufacture of buttons, and in the mode of fastening the same. (A communication.)

Dated May 27, 1862.

1595. C. H. Hudson, merchant, Roxbury, U.S. Improvements in defensive armour.

Dated May 29, 1862.

1611. J. Hirst, jun., Dobcross, Saddleworth, and J. Wood, Birkby, Huddersfield. Improvements in stereoscopic apparatus.

1615. J. D. Lee and J. Crabtree, Shipley, near Bradford, machine makers. Improvements in looms for weaving.

1617. C. D. Abel, 20 Southampton-buildings, Chancery-lane. Improvements in apparatus for raising, propelling, or exhausting air, water, or other fluids, or gases. (A communication.)

1619. J. Paterson, Wood-street, warehouseman. An improved hemmer or instrument for turning over the edges of a binding or strip of linen or other material and preparing it for stitching in sewing machines.

1620. W. Clark, 53 Chancery-lane, engineer. An improved method of throwing the shuttles of looms. (A communication.)

1621. N. Lawton, machine maker, and R. P. Whitworth, foreman, Stalybridge, Chester. Improvements in engines for carding cotton and other fibrous materials.

Dated May 30, 1862.

1623. W. Footman, 5 Great Queen-street, Westminster. Improvements in the treatment and use of sewage and liquid manures, and in reservoirs and pipes to be used therein.

1627. R. Nicholson, Copt Hewick, Ripon, machine maker. Improvements in the construction of lawn mowing machines.

1629. J. Morrison, Birmingham, engineer and machinist. Improvements in the construction of springs, suitable for ladies' dresses or crinolines, and for chair, so a, and other seatings, as well as for bedstead and couch sackings.

1631. H. P. Burt, Charlotte-row, Mansion-house. Improvements in protecting wooden posts from decay, more particularly applicable to posts for supporting electric telegraph wires.

1633. T. N. Pengelly and W. Byron, Charlotte-street, Whitechapel, engineers. Improvements in apparatus for hoisting goods.

1635. R. E. Lofft, Troston, Bury St. Edmunds, gentleman. Improvements in small fire-arms and cartridges.

Dated May 31, 1862.

1637. A. Gilbey, Oxford-street, London, wine merchant. Improvements in the construction of packing cases or boxes for holding bottles either full or empty.

1639. G. Ermen, thread manufacturer, and R. Smith, machinist, Manchester. Certain improvements in machinery for spooling and balling sewing threads, silk, yarn, and other like fibrous materials.

1643. R. Shortrede, Brighton, major general in Her Majesty's Indian army. Improvements in presses for pressing cotton and other articles.

1645. H. Watson, Newcastle-upon-Tyne, engineer, and J. Millbourn, Dartford, paper manufacturer. Improvements in pulp strainers or knotter bottoms.

1649. G. C. Lingham and J. Nicklin, button manufacturers, stampers, and piercers, Birmingham. An improved crinoline connector and suspender.

Dated June 2, 1862.

1655. J. King, Moss Mill, Rochdale, cotton spinner, and J. Partington, overlooker. Certain improvements in looms for weaving.

1657. A. J. Sax, Paris, musical instrument maker. Improvements in kettle, big, or other drums.

1658. T. Cambell, Leeds, machinist. Improvements in apparatus for "witneying" piled fabrics.

1659. C. H. Roeckner, Marsh-street, Bristol. An improved method of constructing coffer dams and other similar structures for excluding or keeping back the flow of water and preventing inundations.

1661. J. Key and F. Potts, Birmingham. Certain means of producing designs in iron, and in the application of the same or designs formed in like manner of other metals to the manufacturing and ornamenting of bedsteads and other metal articles of furniture.

1663. J. Whitworth, Manchester. Improvements in shells.

1665. E. Lloyd, Bow Paper Mills, paper maker. Improvements in machinery for the manufacture of paper.

1667. J. Marson, Birmingham, gun manufacturer. A new or improved projectile for small arms and ordnance of every description.

Dated June 3, 1862.

1671. W. H. Hall, Birmingham, miners' lamp manufacturer. Improvements in miners' safety lamps.

1673. J. Biers, 5A Tottenham-court-road. Improvements in shoes for horses and other animals.

1675. J. L. Norton, Belle Sauvage-yard. Improvements in machinery for raising and forcing water.

Dated June 4, 1862.

1677. A. H. Perry, Brighton, railway inspector. Improvements in fastenings for and in the method of fastening together or securing railway chairs and sleepers and for other similar purposes.

1681. T. Allcock, Ratcliffe-on-Trent, Nottingham, agricultural implement manufacturer and mechanist. Improvements in the construction of horse-rakes.

1683. G. Allibon and E. Snell, Lewisham, engineers. Improvements in surface condensers and superheaters.

1685. I. and G. Battinson, Halifax, York, machine woolcombers. Improvements in machinery for combing wool and other fibres.

1687. F. P. Preston, Counter-hill, New-cross, engineer, and C. Goodman, George-street, Deptford, engineer. Improvements in the permanent way of railways.

1689. S. Huston, Deeping St. James, Lincoln. Improvements in safety valves.

Dated June 5, 1862.

1697. J. Keatley, Warwick, commercial clerk, and J. Tangye, Birmingham, manufacturer. An improvement or improvements in lifting jacks.

1698. R. Sill, Birmingham, grocer and tea dealer. An improved method of attaching direction cards, name plates, or other cards or plates, to trunks, packing cases, and other articles.

1699. P. M. Parsons, Blackheath, C.E., Improvements in ordnance, and in tools for rifling the same, parts of which improvements are applicable to small arms.

1701. E. Conroy, Boston, U.S., machinist. Improved machinery for cutting corks, bungs, and such like articles.

1703. W. E. Newton, 66 Chancery-lane, C.E. Improvements in the construction of organs and other wind instruments, parts of which improvements are also applicable for regulating the pressure and flow of gas and air. (A communication.)

Dated June 6, 1862.

1705. E. Death, Liecester, engineer. Improvements in road locomotives or traction engines.

1707. W. R. Jeune, Flower-terrace, Campbell-road, Bow. Improvements in the manufacture of fabrics suitable to be used as substitutes for solid leather.

Dated June 7, 1862.

1710. A. J. Adams, Devonport, naval outfitter. An improved method of rifling fire-arms.

1711. G. D. Hatton, Manchester, wholesale stationer and bookbinder. Improvements in presses.

1713. C. Hook, Bridgwater, Somerset, cutler. Improvements in the construction of steam engines.

Dated June 9, 1862.

1715. W. H. Turner, Blackburn, Lancaster, cotton spinner. Improvements in engines for carding cotton and other fibrous materials.

1719. J. M. R. Catteau, 333 Rue Saint Martin, Paris. Improvements in machinery for twisting wool, cotton, flax, silk, and other fibrous threads.

1721. F. Giachosa, Guy's Cliff Villa, Warwick. Improvements in ventilating mines, ships' holds, and other places.

1723. A. Knowles, Birstal Dye Works, Birstal, near Leeds, dyer and wool extractor. Improvements in apparatus for washing extracted wool and other fibre.

Dated June 10, 1862.

1727. J. A. Pols, Nye's-wharf, Grand Surrey Canal, Old Kent-road. An improved method of refining oils.

1728. N. Davis, 25 The Cedars, Putney. An improved propeller for ships or vessels.

1729. G. T. Jourdain, St. Paul's-terrace, Canonbury. Improvements in treating cocoa-nut oil.

1731. J. Alison, Brightland's, Reigate. Improvements in harrows, and in the apparatus for steering or guiding of such and other agricultural implements.

1732. J. B. Ingle, 37 King William-street, City, gentleman. Improvements in reaping and mowing machines. (A communication.)

1733. J. G. Appold, Wilson-street, Finsbury-square, gentleman. Improved apparatus for regulating the discharge of water and other liquids and air and other gases.

Dated June 11, 1862.

1735. W. Lennan, Dawson-street, Dublin, saddle and harness maker. An improved safety stirrup.

1737. H. Bland, Stuart-street, Luton, Bedford. Improvements in sewing machines.

1739. W. Crook, Blackburn, Lancaster. Improvements in looms for weaving.

1741. J. Marsh, New Sneinton, near Nottingham, machinist. Improvements in the manufacture of lace, and in the machinery employed therein.

1743. B. W. Gerland, Newton-le-Willows, Lancaster, chemist. Improvements in the manufacture of sulphate of copper, and in obtaining metals from the material used in such manufacture.

1745. J. Hetherington, Manchester, machine maker. Improvements in lubricating revolving surfaces.

Dated June 13, 1862.

1756. G. Haseltine, 100 Fleet-street, American barrister-at-law. Improvements in the construction and application of rails for railways. (A communication.)

1758. J. Wilson, 7 Albert-square, Clapham-road. Improvements in the construction of ships for war purposes, applicable also to the mercantile marine.

1760. C. A. Tyler, Birmingham, corn dealer. A new or improved holder for holding dinner and other plates and dishes, and for other like purposes.

1764. W. E. Newton, 66 Chancery-lane, C.E. An improvement in elongated bullets. (A communication.)

Dated June 14, 1862.

1768. T. Williams, 14 Red Lion-street, Clerkenwell, smith and engineer, and H. Cox, 22 Lower-street, Islington, gas engineer. Improvements in churns, partly applicable to washing machines.

1770. J. G. A. Dallot, L'Isle, Adam, France, joiner. A new portable circular saw.

1772. J. H. Johnson, 47 Lincoln's-inn-fields, gentleman. Improvements in Jacquard machines. (A communication.)

1774. R. A. Brooman, 166 Fleet-street, patent agent. Improvements in coking ovens, in collecting and utilizing the products resulting from the distillation or carbonization of coal and other matters producing coke, and in apparatus employed therein. (A communication.)

1776. R. Hicks, Kensington-park-terrace, gentleman. Improvements in the manufacture or preparation of paints, pigments, and colours.

Dated June 16, 1862.

1780. G. H. Birkbeck, 34 Southampton-buildings, Chancery-lane, engineer. Improvements in the construction of presses for extracting liquids from various substances. (A communication.)

1782. W. J. Curtis, Tufnell-park-road, Holloway, C.E. An improvement in the construction of screw propellers.

Dated June 17, 1862.

1784. J. E. Holmes, South-parade, Trafalgar-square, Chelsea, mechanical and civil engineer. Improved machinery for digging or cultivating land. (A communication.)

1790. J. Nield, iron founder, and T. A. Nield, engineer, Dukinfield, Chester. Improvements in moulding or manufacturing pipes, columns, or other similar articles of cast iron or other metals.

1794. W. Clark, 53 Chancery-lane, engineer. Improvements in the manufacture of buttons, and in apparatus for the same. (A communication.)

Dated June 18, 1862.

1798. J. H. Johnson, 47 Lincoln's-inn-fields, gentleman, Improvements in projectiles. (A communication.)

1800. F. Coltman, Normanton, York, carpenter. Improvements in apparatus for discharging coals, minerals, or other substances.

Dated June 19, 1862.

1804. G. Speight, 5 Saint John-street-road, manufacturer. An improvement in the manufacture of head ornaments.

1808. R. Stansfield, iron founder and machinist, and J. Dodgeon, mechanic, Todmorden, Lancaster. Improvements in looms for weaving.

1810. M. Wigzell, Strand, Topsham. Improvements in the form of bolts and other fastenings for shipbuilding and other purposes.

1812. J. B. Wood, Vernon-house, Camp-street, Broughton, near Manchester. Improvements in the manufacture of driving straps or bands, the backs of wire cards and cop tubes.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

1839. G. T. Bousfield, Loughborough-park, Brixton. Certain new and useful improvements in steam engine valves. (A communication.) Dated June 21, 1862.

1845. G. Haseltine, 100 Fleet-street, American barrister-at-law. Improvements in machinery for mowing and reaping, the driving gear employed being applicable to machines for other purposes. (A communication.) Dated June 23, 1862.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

424. T. Birdsall and J. Birdsall. Preparing hides.
428. R. Watkins. Oil and spirit lamps.
430. J. Lees. Trap.
433. W. Bush. Omnibuses.
435. C. T. Marzetti and J. Watson. Apparatus for raising and lowering.
443. W. Hinton. Barometers.
444. W. Davis. Illuminating.
450. J. Friedlaender. Preparing flax.
451. E. M. Stoehr. Manufacture of manganese. (A communication.)
459. J. Spence. Weighing, screening, and fanning grain. (A communication.)
461. H. Ward. Ladies' saddles.
465. R. and W. E. Pickin. Manufacture of carriage bodies.
469. H. Chevasse, T. Morris, and G. B. Haines. Manufacture and ornamentation of metallic bedsteads.
473. A. Bornemann. Constructing fountains.
474. J. Millington. Hearse or bier.
476. C. H. J. W. M. Liebmann. Felted fabrics.
480. G. Blakey, S. Blakey, J. Blakey, and B. White. Leggings or gaiters.
482. B. Foster. Construction of horticultural buildings.
483. W. B. Johnson. Steam engines.
488. J. C. Haddan. Small arms.
489. R. Waller. Machinery and apparatus for joining leather.
497. F. St. G. Smith. Machinery for grinding or reducing quartz. (Partly a communication.)
504. E. Bliss and H. Lamplough. Viewing microscopic photographs and other minute objects.
516. A. Green. Bordering paper, envelopes, and cards.
529. W. P. Savage. Fire-arms.
533. T. Adams. Effecting an equilibrium of the steam pressure upon valves.
550. J. L. Charcouchet. Breaking stone.
554. T. Bradford. Washing machines.
570. J. W. Davis and F. Davis. Supplying feed water to steam boilers.
595. J. Sidebottom. Fire-arms and ordnance.
621. G. Edmonson. Washing machines.
745. M. A. F. Mennons. Arresting headstrong or runaway horses. (A communication.)
751. T. Dunn. Construction of bridges.
799. B. Gladstone. Tilting or tipping waggons.
843. J. Haworth. Conveying telegraphic messages.
863. W. A. Ashe. Driving the propelling shafts of ships or vessels. (A communication.)
1020. E. Funnell. Self-acting indicator signal for railways.
1097. J. Barbour. Hand hammers. (A communication.)
1208. G. Richards. Ordnance.
1473. C. Attwood. Manufacture of steel and iron.
1618. R. Griffiths. Marine propellers.
1650. L. Chaubart. Apparatus for raising the level of water in rivers, canals, and other water courses.
1712. G. Haseltine. Photographic camera. (A communication.)
1812. J. B. Wood. Driving straps.
1839. G. T. Bousfield. Steam engine valves. (A communication.)
1845. G. Haseltine. Mowing and reaping.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed June 27, 1862.

3264. N. McHaffie.
3275. R. A. Brooman.
3276. A. and J. Edward.
2. N. C. Szerelmey.
5. J. Walker.
6. T. C. Clarke.
8. R. A. Brooman.
11. B. Rhodes.
13. W. B. Patrick.
14. E. F. Davis.
20. W. A. Fell.
22. G. Jeffries.
27. W. E. Gedge.
71. J. Carter.
89. T. Gilbert.
131. T. Emmott.
141. L. Barbat.
239. W. E. Newton.
689. E. T. Hughes.

Sealed June 30, 1862.

25. G. Stracey.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

1520. G. Redrup.
1524. T. Howard.
1538. G. Dawes and C. J. Carr.
1540. A. V. Newton.
1541. J. M. J. Baillie.
1557. R. A. Brooman.
1533. G. Wrigley.
1535. B. Burton.
1546. T. Wight.
1552. G. Baker.
1559. T. Bell.
1562. J. A. Wilkinson.
1656. W. A. Munn.

PATENTS ON WHICH THE SEVENTH YEAR'S STAMP DUTY HAS BEEN PAID.

1274. G. Green.
1445. I. J. Silberman.
1456. F. Leiss and C. Schneider.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JULY 11, 1862.

GUNS FOR NAVAL WARFARE.

PROVERBS, it is said, are the concentrated wisdom of ages—axioms of universal acceptation have the value of proverbs. There is no axiom with a better foundation on truth, or better understood and acted upon in this country, than that which says, "if you wish to be "at peace, be prepared for war." It expresses briefly and tersely the foreign policy of the British Empire. For England, whose might and power are in her naval armaments, there is no preparation for war more intensely practical or imperative than the possession of the most effective gun in the world for naval warfare.

We are glad to show that in devoting so large a space in our columns as we have lately done to warlike questions, we are the advocates of peace, and it is in that point of view we propose to call attention to the interesting discussions which took place at the recent meetings of the Royal United Service Institution. We shall take occasion to pass in review the merits of the different kinds of guns used or proposed for the service, and endeavour to assist the public in forming correct notions out of the discordant and naturally interested or prejudiced statements of rival inventors and their partizans.

On the first day of the meetings referred to, the Duke of Somerset, First Lord of the Admiralty, in the chair, a paper was read by Captain E. Gardiner Fishbourne, R.N., C.B., on "the "character of gun best adapted for naval war- "fare, as gathered from the various plans of "guns proposed."

The subject excited so much interest that the meetings extended over three successive evenings, and were numerously attended by naval and military officers, as well as engineers, gun manufacturers, and men of science, amongst whom General Anstruther, Col. Wilford, R.A., Lieut-Colonel Clay, Col. Lefroy, R.A., Capt. Blakely, Sir W. Armstrong, Vice-Admiral Sir Fred Grey, Mr. Charles Lancaster, Mr. Haddan, Mr. Bashley Britten, Mr. Michael Scott, C.E., Commander Scott, Admiral Taylor, C.B., Admiral Halsted, and Mr. G. Rendel, took part in the discussion in the order in which they are named.

Nothing could be more calm, candid, explicit, or intelligible, than the able exposition of Captain Fishbourne's views, which he illustrated with diagrams, tables, and references to artillery experiments. It was at once instructive and suggestive, and it had the merit of bringing forward the inventors of different systems of guns, to take part in the discussion and explain the principles and modes of construction of their inventions, each in turn attacking his competitor,—an excellent way of getting at the truth.

We have observed with regret that scientific meetings have too often been made the occasion for inventors or manufacturers to advertise their plans or processes. We do not know whether the same idea floated in the mind of Captain Fishbourne, but we heard him with pleasure conclude his address by "calling on "those gentlemen who have displayed so much "talent in working out their respective plans "to look at the question less from a personal "and more from a national point of view."*

* He has a right to hold this language, because he is not a gun inventor, or an interested partizan. He is an impartial judge.

The Duke of Somerset cordially echoed that sentiment, and alluding probably to some hard blows aimed at a particular kind of gun which has received an unlimited amount of national support, His Grace expressed a hope "that the "discussion would be carried on by those "who had considered the subject, fairly and "calmly."

We will follow this rule, although we cannot say it exercised its full influence on all those who addressed the meeting. One remarkable effect of the freedom with which the different speakers delivered their sentiments is, that the kind of fascination, which the supposed super-excellence of the Armstrong gun held over the minds of professional men, is dissipated; and many of its ardent admirers have learnt that possibly there may exist other guns which not only equal but surpass it in efficiency. This change of opinion is the effect of the plain, manly, outspoken manner in which the gallant officer recanted the favourable opinion he had once been led to form of Sir W. Armstrong's system. "Having been captivated (he said) "by the beauty of the mechanism of the Arm- "strong gun, its great ranges, reported accuracy, "and the undoubted genius of its constructor, "I incidentally gave in this place a too un- "qualified assent to all that had been claimed "for it. Finding that, in some respects, I had "been misinformed on a point of such national "importance, it became my duty to give equal "publicity to my withdrawal of that assent."

This proves the honesty of his conviction, and leads one to the reflection that the extravagant praise lavished on this gun in official reports, and in the naval and military intelligence of a great contemporary, have produced the usual effect of exaggeration which, by creating a reaction, will help to remove a delusion that for the national interest has been too long kept up.

In our preliminary summary of the elaborate details contained in the paper which opened the proceedings, and in the discussions which followed, we can only touch upon the leading points necessary to give our readers a correct notion of the state of this important question. Captain Fishbourne, reviewing the great change in naval warfare, which must result from the conversion of men-of-war into iron-clad vessels, goes straight to the conclusion, that actions at sea will henceforth be fought at short ranges, or, which is the same thing, that long shots will be comparatively innocuous. He shows, by the most conclusive reasoning, founded on facts and acknowledged scientific data, that from disturbing and unavoidable causes in naval warfare the accuracy of rifled guns cannot be relied upon, and that, in fact, the very excellence of the rifled Armstrong ordnance—its nicety of adjustment and perfect aim, which are its chief merits—render it unfit for naval service. At short range the initial velocity and penetrating force of the rifled 110-pounder is less than the smooth-bore 68-pounder, to which he gives the preference; and having cited a pamphlet by Mr. Michael Scott, C.E., in which the value of smooth bore guns and improved shot are set forth, he enumerates the conclusions he has come to in the following terse passage: "To the extent that "we have adopted rifled guns, to the exclusion "of smooth-bores, for the navy, we have given "up the substantial advantages of low trajec- "tories, straight ricochet, smashing force, "simplicity, and economy, for the very occa- "sional advantages of long range. Therefore, "for efficiency, no less than for economy, we "must revert to the smooth-bore in principle, "and invest talent and money to develope its "merits."

More truths, each of great value, and stronger arguments in forcible language, which even the unprofessional can understand, could not be comprised in fewer words. In support of his conclusion he quotes a *dictum* of Sir H. Douglas, that "the main principle which "should govern our choice of naval guns, is to "prefer those which, with equal calibre, "possess the greatest point-blank range;" and adds, "this was the correct view to have taken "before the introduction of iron-coated ships; "since that we have no choice, as no other "guns will be completely effective against iron "plates, if against other ships either."

He then gives his opinion, "that breech- "loaders should be excluded, as they are "dangerous," and he condemns the coil system for the following reasons:—"The coils are "shrunk on hot; the metal, of course, con- "tracts in every direction, consequently the "joints open—it were impossible they should "be close—the overlapping pieces at the joints "indicate the knowledge of this defect. All "these points of weakness, and the whole of "the great vibration which takes place every "time the gun is fired, must be thrown in turn "on these separate parts, and not distributed, "owing to the continuity being broken, which "must lead early to the disintegration of the "gun." He concludes by insisting that "the "maximum initial velocity is the primary con- "sideration," and he shows by a train of undeniable argument, that this can only be attained by firing round shot with high charges from a smooth-bore gun. As to shells, although he admits the excellence of the Armstrong rifled gun for throwing them at long ranges, he considers "the uncertainty and danger of high "charges (with rifled guns) is such that it "becomes a question whether, even for special "though unfrequent service, they should be "used on shipboard."

Many other considerations relating to the construction of guns and artillery practice at sea are ably and fairly dealt with. All the points of the question, velocity, penetrating effects, trajectories at long and short ranges, windage, rifle grooving, recoil, are examined *seriatim* in this remarkable paper, which, together with the discussion to which it gave rise, supplies a mass of valuable information, from the analysis of which, from time to time, we hope to be able to extract the truth, and lay open to our readers the *arcana* of the science of gunnery. That this, perhaps, is not an easy task, that popular instruction is much wanted on this subject, will, we think, be admitted when the noble Duke who presided at the first day's meeting, found it necessary, in taking a neutral position, to say:—"I have read a great "deal, and heard a great deal, about guns of "all kinds; of what I have heard there is a "great deal I do not believe, and very little "that I do believe." When the first Lord of the Admiralty makes this admission, we can understand how helplessly the board, in the exercise of its executive duties, relies upon the Controller's Department; and it furnishes the strongest proof that that department, or some other properly constituted body, should possess the scientific and practical knowledge, on all technical matters, necessary to guide the administrative branch of the Admiralty.

Sir William Armstrong's system was rudely assailed by other speakers. He had to defend it from multitudinous attacks. We will not say he was not equal to the occasion, but he was not prepared on the first night to "answer "the large number of facts advanced, or on "the spur of the moment to go into a complete "refutation." On the following evening he came forward with his defence, which we will com-

ment upon on another occasion. In the meantime, we may say the *prestige* of the Armstrong gun is gone. Stripped of the rhodomontade of partizan writers, the whole question of gunnery, thanks to the lucid and courageous exposition of Captain Fishbourne, will be rationally and dispassionately reviewed.

THE ORDNANCE SURVEY.

HAVING recently had an opportunity of inspecting the vast establishment at Southampton, known as the Ordnance Survey Office, and being deeply impressed by the importance of the work in progress there, we have this week the pleasure of laying before our readers the results of our observations. It may be well to state primarily that the survey of the United Kingdom is based upon and connected with a triangulation which extends over the whole country. The distance between the trigonometrical stations are derived from measured base lines on Salisbury Plain, and on the shore of Lough Foyle, in the north of Ireland. This most important, and indeed vital branch of the work, has been executed with the greatest possible degree of accuracy, the difference between the measured lengths of the bases of verification and their computed lengths not exceeding two and a-half inches in seven miles. In effecting this extraordinary degree of exactitude, a standard bar of iron has been used for the purposes of measurement, and, of course, on all occasions of the employment of this instrument, the temperature was taken into account. A few degrees higher or lower on the thermometric scale, as our readers are aware, would tell in the shape of expansion or contraction on a bar of iron, and hence the necessity for extreme care in using it as a standard of measurement.

The average length of the sides of the triangles in the principal triangulation is about 60 miles; but many of the sides exceed 100 miles in length. The primary triangulation is next broken up into smaller triangles, the sides of which are from five to ten miles long, and this second system of triangulation is again broken up into triangles, the sides of which are about one mile long. These form the tertiary, or minor triangulation.

The persons employed to make the detailed survey next actually measure the length of each side of the minor triangles on the ground, noting down most carefully in their "field-books" every fence, stream, or other object they may happen to meet with in the operation. They then measure cross lines from one side of the triangle to the other, and by taking off-sets from the measured lines to every object on the face of the country, they obtain in their field-books the data for plotting accurate plans of the country to any scale that may be required. The length of every measured side of a triangle is, therefore, checked by the computed trigonometrical distance, while the accuracy of the lines within each triangle is checked by the plotting, and thus the risk of error on the part of the surveyors is completely obviated. It will be seen, indeed, that by this method not only is perfect accuracy of measurement obtained, but every object is placed in its exactly relative position to every other object, however distant. Thus, for example, any house shown on a plan of part of the centre of the kingdom is not only in its correct relative position to any other house in its own immediate neighbourhood, but it is also shown in its correct relative position to any and every house from Cornwall to Caithness. It is needless for us to point out the exceeding value of exactness in making these preliminary measurements, because it will be obvious to all. The corps of Royal Engineers, to whom the work is entrusted, are, however, so well trained in their duty, that they perform it unerringly, and the checks employed, in ninety-nine cases out of a hundred, only demonstrate the correctness of their labours.

As regards the levels which are engraved on the plans issued from the Ordnance Survey Office, they are all given in relation to one datum level. That for Great Britain is the level of mean tide at Liverpool, and in relation to this principal lines of levels have been carried all over the kingdom, from Cape Wrath to Land's End. Thus, again, the levels which are published on the plans are strictly correct, relatively to each other, no matter how widely separated the places may be.

The scales which have so far been adopted for the Ordnance Survey of Great Britain are as follows :—

TOWNS—$\frac{1}{500}$ of the actual linear measure.

PARISHES—$\frac{1}{2500}$, or 25,344 inches to a mile, in cultivated districts.

COUNTIES—6 inches to a mile.

THE KINGDOM—1 inch to a mile.

The parish plans on the 25-inch scale, or the scale of one inch to one acre, have been traced, and thirty copies taken by the process of zincography. The whole of the parish plans would have been treated in the same way; but a decision of the House of Commons some time since caused the making of such plans to be discontinued. Tables containing the area of each separate enclosure are published with the thirty plans in question. Each street is to be obtained separately. Collectively they are one and a half miles long, and one mile wide, and, therefore, contain an area of 960 acres.

The plans of parishes on the $\frac{1}{2500}$ scale have been published. These have been multiplied either by the lithographic, zincographic, or the anastatic process. The first mode has fallen somewhat into disuetude at Southampton, but it may not be improper to give some sort of description of the process here, as well as of those which have, to a certain extent, supplanted it. There are some points of difference in the lithographic operation as relating to mapping and ordinary lithography, and this will justify our explanations of the former. The plan is first traced with lithographic ink on tracing paper, which has first been thinly coated with starch or paste. For the sake of economy, the general outline is traced by boys, the forests, woods, and figures being stamped, or, in other words, imprinted by the same youthful artists. Thus the writing and other details which require delicate manipulation alone remain for the duty of the practised draftsman. The lines on the tracing require to be, and must be, boldly drawn. When completed, the tracing is laid between sheets of damp paper, and is thus made ready for transference to stone. This is previously polished by aid of pumice-stone until a good surface is obtained, the final polish being administered by the use of a piece of "water of "Ayr" stone, or other steatite. The lithographic stone thus prepared for its important duty, next receives the tracing. The whole is passed now about a dozen times through the lithographic printing press, care being taken to damp the tracing occasionally during the process. The paper is then removed, and it will be found that the ink from the tracing has adhered to the stone to which, therefore, the drawing has been transferred.

Great care is required during this operation, so as to preserve the surface of the stone from the contact with oil or grease, for both of which it has a great affinity. The next process is to etch the stone with diluted nitric acid, and afterwards to pour on it a solution of gum-arabic. The acid effects a chemical change on the surface of the stone, and thus diminishes its attraction for grease. It also removes any particles of grease which may have adhered to the stone, and, by opening its pores, enables it the better to imbibe moisture. The gum water fills up the pores, and prevents the blank parts of the stone from taking up the ink in printing. The stone is next washed over with turpentine, to remove all but the fatty portions of the transfer ink, after which the printing roller is passed over it, or it is rubbed with a piece of flannel charged with printing ink, which is, perhaps, better in its results than the roller.

When the lines have thus been sufficiently charged with ink, the printing is commenced, the paper on which the impressions are to be taken being previously damped. After each impression, the printing roller is passed over the stone, which is also kept damp by sponging. Usually, the sheets resulting from these operations are clear and truthful, the percentage of failures being small indeed. The disadvantage attending the work is, however, in the great weight of the stones, and their liability to fracture. Hence it is that at the Southampton Works zinc has been of late largely substituted.

The zinc plates intended for map-printing are usually about $\frac{1}{8}$th of an inch in thickness. They are prepared by careful rubbing, in the first place, with "water of Ayr," stone and finishing off with the finest sand, and water applied by aid of a zinc muller. The drawing is made, and transferred, as in the lithographic process; but instead of using nitric acid, the zinc plate is etched with a solution of nut-galls. Should any alteration be required in the drawing after transfer, the defective work may be removed by the application of "water of Ayr" stone, or the lines may be obliterated by the application of a solution of fused potash. It is astonishing, however, to what a slight depth the lines actually extend, and how soon, therefore, a zinc plate may be freed from them, and made ready to receive other impressions.

We come now to what is known as the Anastatic process, which is patented, and which promises, when fully developed, to be of immense value. Briefly it may be said that by its means a print, however old, and if originally made by a greasy ink, may be transferred to a zinc plate, and then that copies to any extent are obtainable by printing from the plate.

In successfully employing the Anastatic process, it must be first ascertained, by rubbing a piece of thin paper over some part of the drawing which it is intended to copy, whether the ink is so fixed as that no trace of it will come off by pressure. If this prove to be the case the drawing or print must be immersed for some minutes in a hot solution of strontia—in the proportion of about one ounce of strontia to a quart of water. This has the effect of loosening the ink. The drawing or print must next be partially dried, and afterwards immersed in a solution of nitric acid—in the proportions of one of acid to six of water. If the print be comparatively new, the strontia bath may be dispensed with, that of the acid being sufficient.

The drawing is then ready to be transferred to a zinc plate, previously polished with flour of emery. This done, a sheet of paper, damped with nitric acid, is placed over the drawing, and the press is put into requisition. The transfer is effected by passing the plate through an ordinary copper-plate printing press. After-

wards the drawing is removed, and the plate wiped over with gum-water. It is then charged with printing ink, and subsequently etched with phosphoric acid, of which a few drops are mixed with gum-water. The plate is thus made ready for printing, and may be used in a manner precisely similar to that spoken of in reference to zincography. We have said that the Anastatic process is likely to become one of great practical value; and, indeed, it is difficult to see where its usefulness will end. On the occasion of our recent visit to the Survey Office, we observed that a portion of the celebrated and original Domes-day Book was being copied by these means. The results, so far as the proof sheets shown to us went, were admirable. Fac similes of the ancient chronicles of England were being obtained without any apparent injury to the venerable and venerated documents themselves; and it was manifest that ancient prints, engravings, or drawings, might be faithfully copied in the same inexpensive and yet most effectual manner.

We will now speak of the reduction of plans by photographic agency. At the Southampton works this is accomplished with an amount of elegance, ease, and precision which is remarkable. The plans of towns on the $\frac{1}{500}$ scale, and those of cultivated districts on the $\frac{1}{2500}$ scale, are regularly reduced to the scale of six inches to the mile, preparatory to engraving, by photography. The collodion process is employed for the purpose of taking the negative copy. The lens of the camera is a single achromatic meniscus, 3½-inches in diameter, with a principal focal length of twenty-four inches. The mode of procedure is after the following fashion:—The plan to be reduced is attached to a board, which can be, by means of a screw or nut, adjusted to any height above the floor which may be required. The board is also moveable on a central pivot. The camera is placed opposite to it upon a table running upon wheels over a small tramway, laid down on the floor of the photographic room.

The required scale of the reduction is obtained by tracing on the ground glass of the camera a rectangle corresponding on the reduced scale with the rectangle of the plan to be produced. The curvature of the image, and indistinctness of outline from spherical aberration, are both remedied by reducing the diaphragm in front of the lens to a small aperture. The negative, having been obtained upon glass, is placed in the printing frame in contact with sensitive paper, and in this manner as many positive prints as may be required are taken in rapid succession. In thus reducing the plans of the Ordnance Survey, it has been found convenient, first, to colour the houses yellow, by which means they print sharp and black on the paper, the yellow rays having no effect upon the sensitive coating of the glass plate upon which the negatives are taken. The introduction of this process has very much lessened the cost of reducing plans, and saves an immense amount of time and labour.

(To be continued.)

A new discovery in locomotion has been made in France, and it is considered to be of so much importance that a Commission has been appointed by the Emperor to examine and report upon it. M. Girard has constructed the model of a railway adapted for runners like those of a sledge. The runners move in a sort of clog; between this and the rails water is introduced, and thus almost all friction is avoided. Should this plan prove successful on a large scale, much wear and tear, not only of the carriages, but of the passengers' nerves, will be saved. How delightful it will be to slide smoothly over a surface of water, instead of having one's bones dislocated by being rattled over uneven rails, and having one's head stupified by the perpetual clatter.

ANCIENT ROMAN COINERS AND SMASHERS.

It is a well authenticated fact that the Romans of old were adepts in the art of counterfeit coining, and to this day it is no uncommon thing for counterfeit coins, and the moulds by which they are fabricated, to be turned up by the plough of the husbandman, or the spade of the antiquarian, on the sites of Roman cities, and encampments in our own country. In France, too, spurious coins cast by the same ingenious but unscrupulous manipulators are often brought to light. At Lyons, not long since, a large number of moulds, which had evidently been used in the nefarious practice of illegitimate money making, was discovered. The substance of them is a baked white clay, much resembling the pipe-clay of modern times. Their shape is flat, and they are about an inch and a half in diameter. They are about two-tenths of an inch in thickness at the edges, and this is diminished in the centre by the depth of the coin, the type of which remains clearly impressed. Each mould has a notch or indentation on one part of its edge which reaches to the vacant space formed by the body of the impressed coin, and as the flat shape and equality of the circumference of the moulds adapts them for joining together in such an arrangement as to bring the types of heads opposite to those of reverses, it is at once apparent that the furrows made by the indentations served as jets or casting holes to the series.

An ingot of debased silver found at the same time and place as these moulds, the green oxide of which indicated the large amount of copper incorporated with it, leaves no room to doubt that the moulds had been used for obtaining imitations of silver rather than of gold money. It appears, therefore, that the mode of casting spurious coins by the ancient Romans very much resembled that practised by modern Londoners. The quality of the clay used by the old coiners is, however, worthy of remark. This was so excellent and so well prepared that, after the lapse of 1400 years, the moulds are perfect enough to receive several castings.

One of the enactments of the celebrated Theodosian code of laws recognised the class of offence referred to, and prescribed a punishment for it. Freely translated, this runs as follows:—"If any one shall fabricate coins by false casting, we command all his property to be given up to the Treasury, in order that the business of coining may be carried on only in our own Mints." We question whether a law of this nature would be of much value in England as a determent from the commission of the crime, for it is now usually perpetrated by those whose property, if confiscated, would add little to the "balance in hand" of the Chancellor of the Exchequer. The Roman rogues understood the art of false coining too by the plating process, but casting was the favourite method; and Pliny remarks that so dextrous were they at the work, that it was often difficult to distinguish a genuine from a base coin. Some of the latter, indeed, he asserts, were so well executed that the curious often gave many good coins in exchange for a false one. The decline of the art of engraving, which in the time of Septimus Serverus had become very noticeable, together with the alteration made in the standard of money by that monarch, were very favourable to forgers and false coiners, and made their deceptions more easy. The number of moulds discovered at various periods at Lyons, and in its neighbourhood, makes it more than probable that these false coiners existed then in great numbers during the Roman occupation. At Rome itself it is on record that so considerable were they in number, that in the time of the Emperor Aurelius they formed a little army; and as a proof of the good understanding existing among them, it may be mentioned that when they were threatened with punishment they revolted against his Imperial Majesty, and killed at the first onset 7,000 of the regular troops! This fact will probably be deemed sufficient to demonstrate the extent to which coining and smashing were carried on when Rome was mistress of the world. The practice of imitating coins of the realm began almost simultaneously with the invention of money, and there is something so tempting about it, that it is likely to continue in existence so long as coin is required and used for the purposes of traffic—that is till the millenium—the date of which perhaps Dr. Cumming will tell us. Meantime the principal safeguard for the public lies in the faultless ornamentation and manipulation of genuine coins, and to these points every state should scrupulously attend. It is highly improper to issue coins from any mint which, from imperfect workmanship or slovenly engraving, invite the skill of the counterfeiter to imitate them. Repressive laws have their influence no doubt, but to make the crime of false coining an impossibility by the means described seems to us the best way of suppressing it.

ON FORCE.*

The existence of the International Exhibition suggested to our Honorary Secretary the idea of devoting the Friday evenings after Easter of the present year to discourses on the various agencies on which the material strength of England is based. He wished to make iron, coal, cotton, and kindred matters, the subject of these discourses; opening the series by a discourse on the Great Exhibition itself; and he wished me to finish the series by a discourse on "Force" in general. For some months I thought over the subject at intervals, and had devised a plan of dealing with it; but three weeks ago I was induced to swerve from this plan, for reasons which shall be made known towards the conclusion of the discourse.

We all have ideas more or less distinct regarding force; we know in a general way what muscular force means, and each of us would less willingly accept a blow from a pugilist than have his ears boxed by a lady. But these general ideas are not now sufficient for us; we must learn how to express numerically the exact mechanical value of the two blows; this is the first point to be cleared up.

A sphere of lead weighing 1lb. was suspended at a height of 16 feet above the theatre floor. It was liberated, and fell by gravity. That weight required exactly a second to fall to the earth from that elevation; and the instant before it touched the earth, it had a velocity of 32 feet a second. That is to say, if at that instant the earth were annihilated, and its attraction annulled, the weight would proceed through space at the uniform velocity of 32 feet a second.

Suppose that instead of being pulled downward by gravity, the weight is cast upward in opposition to the force of gravity, with what velocity must it start from the earth's surface in order to reach a height of 16 feet? With a velocity of 32 feet a second. This velocity imparted to the weight by the human arm, or by any other mechanical means, would carry the weight up to the precise height from which it has fallen.

Now the lifting of the weight may be regarded as so much mechanical work. I might place a ladder against a wall, and carry the weight up a height of 16 feet; or I might draw it up to this height by means of a string and pulley, or I might suddenly jerk it up to a height of 16 feet. The amount of work done in all these cases, as far as the raising of the weight is concerned, would be absolutely the same. The absolute amount of work done depends solely upon two things: first of all, on the quantity of matter that is lifted; and secondly, on the height to which it is lifted. If you call the quantity or mass of matter m, and the height through which it is lifted h, then the product of m into h, or mh, expresses the amount of work done.

Supposing, now, that instead of imparting a velocity of 32 feet a second to the weight we impart twice this speed, or 64 feet a second. To what height will the weight rise? You might

* Lecture by Prof. Tyndall at the Royal Institution, June 6th, 1862.

be disposed to answer, "To twice the height;" but this would be quite incorrect. Both theory and experiment inform us that the weight would rise to four times the height: instead of twice 16, or 32 feet, it would reach four times 16, or 64 feet. So also, if we treble the starting velocity, the weight would reach nine times the height; if we quadruple the speed at starting, we attain sixteen times the height. Thus, with a velocity of 128 feet a second at starting, the weight would attain an elevation of 256 feet. Supposing we augment the velocity of starting seven times, we should raise the weight to 49 times the height, or to an elevation of 784 feet.

Now the work done—or, as it is sometimes called, the mechanical effect—as before explained, is proportional to the height, and as a double velocity gives four times the height, a treble velocity nine times the height, and so on, it is perfectly plain that the mechanical effect increases as the square of the velocity. If the mass of the body be represented by the letter m, and its velocity by v, then the mechanical effect would be represented by $m\ v^2$. In the case considered, I have supposed the weight to be cast upward, being opposed in its upward flight by the resistance of gravity; but the same holds true if I send the projectile into water, mud, earth, timber, or other resisting material. If, for example, you double the velocity of a cannon-ball, you quadruple its mechanical effect. Hence the importance of augmenting the velocity of a projectile, and hence the philosophy of Sir William Armstrong in using a 50lb. charge of powder in his recent striking experiments.

The measure then of mechanical effect is the mass of the body multiplied by the square of its velocity.

Now in firing a ball against a target the projectile, after collision, is often found hissing hot. Mr. Fairbairn informs me that in the experiments at Shoeburyness it is a common thing to see a flash of light, even in broad day, when the ball strikes the target. And if I examine my lead weight after it has fallen from a height I also find it heated. Now here experiment and reasoning lead us to the remarkable law that the amount of heat generated, like the mechanical effect, is proportional to the product of the mass into the square of the velocity. Double your mass, other things being equal, and you double your amount of heat; double your velocity, other things remaining equal, and you quadruple your amount of heat. Here then we have common mechanical motion destroyed and heat produced. I take this violin bow and draw it across this string. You hear the sound. That sound is due to motion imparted to the air, and to produce that motion a certain portion of the muscular force of my arm must be expended. We may here correctly say, that the mechanical force of my arm is converted into music. And in a similar way we say that the impeded motion of our descending weight, or the arrested cannon ball, is converted into heat. The mode of motion changes, but it still continues motion; the motion of the mass is converted into a motion of the atoms of the mass; and these small motions, communicated to the nerves, produce the sensation which we call heat. We, moreover, know the amount of heat which a given amount of mechanical force can develop. Our lead ball, for example, in falling to the earth generated a quantity of heat sufficient to raise the temperature of its own mass three-fifths of a Fahrenheit degree. It reached the earth with a velocity of 32 feet a second, and 40 times this velocity would be a small one for a rifle bullet; multiplying three-fifths by the square of 40, we find that the amount of heat developed by collision with the target would, if wholly concentrated in the lead, raise its temperature 960 degrees. This would be more than sufficient to fuse the lead. In reality, however, the heat developed is divided between the lead and the body against which it strikes; nevertheless, it would be worth while to pay attention to this point, and to ascertain whether rifle bullets do not, under some circumstances, show signs of fusion.

From the motion of sensible masses, by gravity and other means, the speaker passed to the motion of atoms towards each other by chemical affinity. A collodion balloon filled with a mixture of chlorine and hydrogen was hung in the focus of a parabolic mirror, and in the focus of a second mirror, 20 feet distant, a strong electric light was suddenly generated; the instant the light fell upon the balloon, the atoms within it fell together with explosion, and hydro-chloric acid was the result. The burning of charcoal in oxygen was an old experiment, but it had now a significance beyond what it used to have; we now regard the act of combination on the part of the atoms of oxygen and coal exactly as we regard the clashing of a falling weight against the earth. And the heat produced in both cases is referable to a common cause. This glowing diamond, which burns in oxygen as a star of white light, glows and burns in consequence of the falling of the atoms of oxygen against it. And could we measure the velocity of the atoms when they clash, and could we find their number and weight, multiplying the mass of each atom by the square of its velocity, and, adding all together, we should get a number representing the exact amount of heat developed by the union of the oxygen and carbon.

Thus far we have regarded the heat developed by the clashing of sensible masses and of atoms. Work is expended in giving motion to these atoms or masses, and heat is developed. But we reverse this process daily, and by the expenditure of heat execute work. We can raise a weight by heat; and in this agent we possess an enormous store of mechanical power. This pound of coal, which I hold in my hand, produces by its combination with oxygen an amount of heat which, if mechanically applied, would suffice to raise a weight of 100 lbs. to a height of 20 miles above the earth's surface. Conversely, 100 lbs. falling from a height of 20 miles, and striking against the earth, would generate an amount of heat equal to that developed by the combustion of a pound of coal. Wherever work is done by heat, heat disappears. A gun which fires a ball is less heated than one which fires blank cartridge. The quantity of heat communicated to the boiler of a working steam-engine is greater than which could be obtained from the re-condensation of the steam after it had done its work; and the amount of work performed is the exact equivalent of the amount of heat lost. Mr. Smyth informed us in his interesting discourse that we dig annually 84 millions of tons of coal from our pits. The amount of mechanical force represented by this quantity of coal seems perfectly fabulous. The combustion of a single pound of coal, supposing it to take place in a minute, would be equivalent to the work of 300 horses; and if we suppose 108 millions of horses working day and night with unimpaired strength, for a year, their united energies would enable them to perform an amount of work just equivalent to that which the annual produce of our coal-fields would be able to accomplish.

Comparing the energy of the force with which oxygen and carbon unite together, with ordinary gravity, the chemical affinity seems almost infinite. But let us give gravity fair play; let us permit it to act throughout its entire range. Place a body at such a distance from the earth that the attraction of the earth is barely sensible, and let it fall to the earth from this distance. It would reach the earth with a final velocity of 36,747 feet in a second; and on collision with the earth the body would generate about twice the amount of heat generated by the combustion of an equal weight of coal. We have stated that by falling through a space of 16 feet our lead bullet would be heated three-fifths of a degree; but a body falling from an infinite distance has already used up 1,299,999 parts out of 1,300,000 of the earth's pulling power, whence it has arrived within 16 feet of the surface; on this space only $\frac{1}{1300000}$ ths of the whole force is exerted.

Let us now turn our thoughts for a moment from the earth towards the sun. The researches of Sir John Herschel and M. Pouillet have informed us of the annual expenditure of the sun as regards heat; and by an easy calculation we ascertain the precise amount of the expenditure which falls to the share of our planet. Out of 2,300 million parts of light and heat the earth receives one. The whole heat emitted by the sun in a minute would be competent to boil 12,000 millions of cubic miles of ice-cold water. How is this enormous loss made good? Whence is the sun's heat derived, and by what means is it maintained? No combustion, no chemical affinity with which we are acquainted would be competent to produce the temperature of the sun's surface. Besides, were the sun a burning body merely, its light and heat would assuredly speedily come to an end. Supposing it to be a solid globe of coal, its combustion would only cover 4,600 years of expenditure. In this short time it would burn itself out. What agency then can produce the temperature and maintain the outlay? We have already regarded the case of a body falling from a great distance towards the earth, and found that the heat generated by its collision would be twice that produced by the combustion of an equal weight of coal. How much greater must be the heat developed by a body falling towards the sun! The maximum velocity with which a body can strike the earth is about 7 miles in a second; the maximum velocity with which it can strike the sun is 390 miles in a second. And as the heat developed by the collision is proportional to the square of the velocity destroyed, an asteroid falling into the sun with the above velocity would generate about 10,000 times the quantity of heat generated by the combustion of an asteroid of coal of the same weight. Have we any reason to believe that such bodies exist in space, and that they may be raining down upon the sun? The meteorites flashing through the air are small planetary bodies, drawn by the earth's attraction, and entering our atmosphere with planetary velocity. By friction against the air they are raised to incondescence and caused to emit light and heat. At certain seasons of the year they shower down upon us in great numbers. In Boston 240,000 of them were observed in nine hours. There is no reason to suppose that the planetary system is limited to "vast masses of enormous weight," there is every reason to believe that space is stocked with smaller masses, which obey the same laws as the larger ones. That lenticular envelope which surrounds the sun, and which is known to astronomers as the Zodiacal light, is probably a crowd of meteors; and moving as they do in a resisting medium they must continually approach the sun. Falling into it, they would be competent to produce the heat observed, and this would constitute a source from which the annual loss of heat would be made good. The sun, according to this hypothesis, would be continually growing larger; but how much larger? Were our moon to fall into the sun it would develope an amount of heat sufficient to cover one or two years' loss; and where our earth to fall into the sun a century's loss would be made good. Still our moon and our earth, if distributed over the surface of the sun, would utterly vanish from perception. Indeed, the quantity of matter competent to produce the necessary effect would, during the range of history, produce no appreciable augmentation in the sun's magnitude. The augmentation of the sun's attractive force would be more appreciable. However this hypothesis may fare as a representant of what is going on in nature, it certainly shows how a sun might be formed and maintained by the application of known thermo-dynamic principles.

Our earth moves in its orbit with a velocity of 68,040 miles an hour. Were this motion stopped, an amount of heat would be developed sufficient to raise the temperature of a globe of lead of the same size as the earth 384,000 degrees of the cen-

tigrade thermometer. It has been prophesied that "the elements shall melt with fervent heat." The earth's own motion embraces the conditions of fulfilment; stop that motion, and the greater part, if not the whole, of her mass would be reduced to vapour. If the earth fell into the sun, the amount of heat developed by the shock would be equal to that developed by the combustion of 6,435 earths of solid coal.

(To be concluded in our next.)

AUTUMNAL EXHIBITIONS IN BERLIN.

ALMOST all our national exhibitions take place in the spring. They are governed by the duration of the London season, after the close of which, about the end of July, exhibitions in London would find no spectators. The fashionable seasons of other capitals, however, occur at different periods. In Paris the season closes with the first five days in May. Then commences the "country-house season," as it is termed, *la saison des chateaux*. This is followed by the "season of watering-places," *la saison des eaux*. This closes at end of October. And in November and December Paris begins to be alive with the re-opening of its operas, and the production of new pieces at the national theatres. With the New Year begins the series of concerts, and then comes the Carnival, followed by the art exhibitions—the Parisian gaities terminating just when ours begin.

"The Season" in many of the German principalities is governed by that of the mineral baths, which, in most places, takes place in the autumn, though at some few of the baths the season closes as early as July or August; but, as a rule, the fashionable season in Northern Germany may be said to take place in the autumnal months, on account of the great influx of foreign visitors at that period. It is on this account that the Berlin Exhibition of Arts takes place in September. In accordance with this regulation, the *Gazette de Prusse* announces that all works intended for this year's exhibition must be sent in before the 16th August, and that the exhibition will definitively open on the 7th of September. English artists, intending to exhibit, should lose no time in obtaining information relative to the detailed regulations to be observed. And our autumnal tourists, who make their trip a northern one this year, should take note of the Exhibition of Berlin as a thing worth seeing during September and October. It is said that the forthcoming display will be of even more than its usual importance.

MINOTAUR TARGET TRIAL.

GREAT ARMSTRONG GUN BURST.

ON Monday last another of those experiments on naval armour which have so important a bearing on our national defences took place at Shoeburyness. There was the usual attendance of Lords of the Admiralty, members of the Iron Plate Committee, a number of naval and military officers, engineers, iron manufacturers, and shipbuilders, as well as several foreigners, including agents of the Danish Government. A more than usual interest was excited on this occasion by the double attraction of the proposed trial of the full powers of attack with the 150-pounder Armstrong smooth-bore gun, and of a supposed improved plan of defence, in the form of an armour-plated target, representing a section of the frigate Minotaur.

The vessels of this class, of which four are being constructed, are designed larger, more powerful, and more effectually protected, than the Warrior. Great pains were taken in the department of the Controllers of the Navy to render the armour plating more effective than that of the Warrior. No new plan was adopted—the same system of enormous plates, teak backing, and through-bolt fastenings, was adhered to but some of the ascertained defects of the Warrior plan were sought to be remedied by dispensing with tongueing and grooving the edges of the plates, reducing the thickness of the teak from eighteen to nine inches, and increasing that of the armour plates from four and a-half to five and a-half inches. These alterations, *without testing their efficiency by experiment*, appear to have given entire satisfaction to the Admiralty, since the construction of the ships of this new class of improved Warriors (as they were called) was commenced some months ago, and the armour plates were ordered, and the greater part of them, we believe, are manufactured, in full confidence, on the part of the authorities, of a complete success. It will be seen by the result of the trial that this expectation was lamentably disappointed. The alterations in a plan already known to be defective, instead of removing, increased its defects, and one is left to wonder at the rash confidence which sanctioned an expenditure of half a million on a doubtful plan, without trial, and after the warning of previous failure, for the Warrior target was anything but a success.

In order to make a fair comparison between the Warrior and Minotaur targets the same frame was used for both. The three 4½-inch plates to the right of the port were stripped off, and replaced by the same number of 5½-inch plates, on nine inches of teak planking, and fastened with through bolts. Another modification consisted of iron plates 10 inches wide and 1½ inch thick, let into the teak, and placed longitudinally at the back of the joints of the centre and top and bottom armour plates. In former experiments, these joints were found to be weak places, and it was thought that the longitudinal plates would support the edges, and impart strength to the structure; but a little reflection might have shown that these back supports affording a hard bearing (iron) to the edges only, and leaving the central parts resting on a comparatively soft material (wood), the armour plates would be more easily penetrated. The target was supposed to be further strengthened by covering the joints of the skin plates, longitudinally, with ⅝ plates 18 to 20 inches wide, let into the back of the teak, and bearing against the outside of the skin.

Four round shot were fired from the 150-pounder Armstrong gun.* The three first were cast-iron, weight 156 lbs.; the last wrought-iron, weight 162 lbs.; the charge in each case was 50 lbs. of powder; the range 200 yards. No. 1 struck the centre plate (which is 9 feet long and 3 feet 4 inches wide) about 2 feet from the port, midway between the top and bottom edges. It penetrated the armour plate, making a hole 12 inches in diameter, and crushing through the teak backing, burst the ship's skin plate open, making three large cracks, through which splinters of wood protruded behind, split one of the frames across, broke off the points and nuts of four armour plate bolts, and four or five wood bolts. Several bolts of the plate above were started by the shock.

No. 2 hit the top plate (which, as well as the bottom plate, is about 11 feet long, and 3 feet 4 inches wide) about 3 feet from the left end, and about the middle between the upper and lower edges. This shot made a hole 12 inches in diameter through the plate, and forced a way through the teak backing and skin plate. Large fragments of the armour plate, including the front piece bearing the mark of the shot, were found on the ground 10 or 12 yards behind the target, and 5 or 6 bolt ends and nuts were broken off. Shelf pieces and caulking plates intended to support the skin plates inside were ripped off at the line of rivets. Two frames were cracked.

No. 3 made a hole, of the same diameter as before, clean through the bottom plate, close to the upper edge, and equidistant from the butts. Large pieces of the shot and armour plate passed through the target; the cone of the shot imbedded in the portion of plate carried away at the moment of impact was picked up some yards in the rear. In addition to the hole through the armour plate, its upper edge was split longitudinally a length of 2 or 3 feet, showing the lamination of rolled iron. Two of the frames behind the skin were further damaged and broken in two, and several bolt ends and nuts broken off.

No. 4 struck the centre plate about 3 feet from the right end. This shot, being of wrought iron, did not break up like the cast iron shot, which invariably fly into fragments, leaving a cone in front, but it flattened and stuck fast in the armour plate, leaving one-third of its diameter outside. This effect arises from the ball squabbing out from its own force, and becoming too large to pass through the hole made at the moment of impact. The diameter of the protruding portion measured 13½ inches, that of the shot being 10 inches. The effect of this missile was more destructive than that of the cast iron shot. Keeping entire it does all its work in damaging the target—whilst the latter expend part of their force in destroying themselves. Large pieces of the armour plate were driven through the target, crushing the wood backing to shreds, bursting a great opening through the skin plates, and completely smashing two more frames.

The discharge of this shot brought the destructive action of the 150-pounder to a close, for this colossal 12 ton gun, about which there has been so much controversy, burst in firing the fourth round. The entire breech end, weighing about 17 cwt., was blown off and carried 50 yards behind. There were no splinters, and no person was injured; but that is not surprising, because previous to every discharge the artillery men gave the dangerous monster a wide berth, the gun being fired by a long lanyard pulled by a gunner who was safely ensconced.

There is no denying that the gun had the best of it in this encounter. The target was so fearfully mutilated, that if it had been a ship afloat, seeing the effect of only four shots, she would have been in as bad a predicament as a timber ship. The injury to the armour plates and to the skin and frame, great as it was, was not so disastrous as the destruction of the fastenings. Three-fourths of the bolts which held the plates were gone. Of thirteen bolts, with which the centre plate was secured, eleven were visibly broken, and probably the other two were also broken, although the heads or nuts had not come off. This damage to the fastenings arises from the plate, when struck, being bulged and driven into the wood backing, which affords no support, but yields to the blow; consequently, the butts buckle and start with a tremendous rebound from their bearings, tearing away the bolts. The three plates were dished—driven in at the centre, and curled up at the ends, one nine inches and the others six or seven inches off from the wood backing. The Duke of Somerset put his finger on the main defect when he said, "I have seen plates after a few shots fall bodily off the side of the vessel, which then was in a worse position than a wooden ship."

But these results, probably, are to be attributed more to the inefficiency of the system of armour plating than to the power of the guns. At all events, it is proved by this last experiment that however defective the armour plating of the Warrior was found to be, that of the Minotaur class is worse; and it is impossible the question can remain in its present state. Two 68-pounder round shot were afterwards fired separately at the bottom plate; they made deep indentations in the iron, but did not penetrate or damage the target.

It was remarked, as a singular exception to the effects of former target experiments, that the armour plates were not cracked at the bolt-holes. The explanation seems to be that the velocity and force of the projectile being so great as to penetrate the plates through and through, owing to the non-resistance of the wood backing, the shot did its work without causing the same amount of vibration as a shot at a lower velocity, on the same principle as a rifle ball will pass through a pane of glass without cracking it. In former experiments, heavy shot at low velocities, and

* The *Times* persists in calling this gun a 300-pounder. This is a misrepresentation. It is a smooth bore made to carry a spherical 10-inch shot, weighing 156 pounds. The pretence for calling it a 300-pounder is, that there was some talk about rifling the gun, and loading it with an elongated bolt of that weight; on the same supposition, a 68-pounder might be called a 136-pounder.

THE ARMSTRONG GUN.

shell which produced only slight indentations in the iron, caused extensive cracks at the bolt-holes.

We cannot close our report of this interesting trial of the power of artillery without putting our readers in possession, so far as we are able, of the precise nature and cause of the damage sustained by the great Armstrong gun. Having taken a prominent part in publishing what we believed to be a correct estimate of the defects of the system, we are anxious to establish the truth, and we hope, with the aid of the annexed diagrams (in which the same letters designate the same parts) to render a description of the present condition of the gun intelligible to our readers.

The manner of the accident, by disclosing two sectional views of the breech at the time of fracture, afforded a complete illustration of the internal construction of the gun, which, if we may judge from the observations of machanical engineers and ordnance constructors who examined the broken parts, was not previously understood by the scientific public.

Fig. 1 represents a longitudinal section before the accident occurred. The muzzle end is truncated in the drawing to save space in our columns. The barrel *C D* in its whole length from the breech to the muzzle suffered no damage. It remained in position on the carriage apparently without a flaw. The line of fracture is 1¾ inches from the inner surface of the breech-piece *B*, which is a solid cylinder 15 inches in length and 15 inches in diameter, forming an enormous screw, which fits into the worm cut into the outer cylindrical mass *A*, the two screwed up forming the breech-end of the gun, which is 30 inches in diameter, and weighs 16 or 17 cwt. Fig. 2 represents the breech separated from the gun, showing the end *B* of the breech-piece projecting 1¾ inches. Fig. 3 is a front view of the section at the line of fracture looking at the breech. Fig. 4 is a similar view looking into the barrel; *A* is the outer mass of the breech; *B* the breech-piece; *C* the coils forming the barrel; *D* the external coils shrunk over the former; *E* a copper disc, against which the outer edge of the face of the breech-piece was tightly screwed up to prevent the escape of gas in the rear; *F* is the bore. The copper disc and screw arrangement at the breech appears to have been the cause of the accident, and, in the opinion of engineers competent to judge, is looked upon as a mechanical blunder. The pressure and close-fitting of the edges of the breech-piece to the copper disc were not sufficient to prevent the escape of gas, which passed behind the disc; consequently, the effect of the explosive force on the breech was not limited to the surface area of the bore of the gun, which is 10 inches, but was extended to the area of the breech-piece, or 15 inches in diameter, an increase in the proportion of 225 to 100. The destructive effect of the enormous pressure was aided by the cut of the screw in the mass *A*, at the first thread of which the fracture took place, leaving 1¾ of the mass *A* in the barrel. The shear of the iron, 7½ inches thick all round, following the nick of the screw cut, is singularly clean and regular. The broken faces present a close granulated texture like cast steel, but the discolouration of the surface by the explosive gas rendered it difficult to form an opinion of the nature of the material.

The results of last Monday's experiments is a severe and double disappointment to the official authorities. The anticipated triumph of the great gun is annihilated at a blow. The theory of destructive capabilities of large guns on iron plates at long ranges is far from being confirmed in practice. If a 150-pounder on the Armstrong system, on which such implicit reliance was placed, bursts with the ordinary charge as a smooth-bore, how can it be expected to stand the immense increase of explosive force when rifled? and what chance does there seem to be that the 300, 600, and 1,000-pounders, on which the Defence Commissioners founded the conclusions of their report, will ever be made available? The wisdom of Parliament in putting an end to the Spithead Forts is demonstrated. On the other hand the terrible damage sustained by the Minotaur target places the Admiralty in the awkward predicament of having to alter the system of armour-plating, for which an enormous expenditure has been incurred, and probably has been thrown away. This comes of trying experiments on a plan after it has been adopted. It is the old story of the stable-door and the horse.

INSTITUTION OF CIVIL ENGINEERS.

THE council of the Institution of Civil Engineers have awarded the following premiums for papers read during the session 1861-62:—

1. A Telford medal, the Manby premium, in books, and a Stephenson prize of twenty-five guineas, to Charles Agustus Hartley, M. Inst. C. E., for his "Description of the Delta, and of the Works recently executed at the Sulina Mouth, of the Danube."

2. A Telford medal, and a Miller prize of fifteen guineas, to John Henry Muller (of the Hague), for his paper "On Reclaiming Land from Seas and Estuaries."

3. A Telford medal, and a Miller prize of fifteen guineas, to John Paton, M. Inst. C.E., for his paper "On the Sea Dykes of Schleswig and Holstein, and on Reclaiming Land from the Sea."

4. A Telford medal, to James Abernethy, M. Inst. C.E., for his "Description and Illustrations of the Works at the Ports of Swansea, Silloth, and Blyth."

5. A Telford medal, to John Bailey Denton, M. Inst. C.E., for his paper "On the Discharge from Underdrainage, and its effect on the Arterial Channels and Outfalls of the Country."

6. A Watt medal, to Joseph D'Aguilar Samuda, M. Inst. C.E., for his paper "On the Form and Materials for Iron-Plated Ships, and the Points Requiring attention in their Construction."

7. A council premium of books, to James Brunless, M. Inst. C.E., for his paper on "Railway Accidents—their causes and means of prevention."

8. A council premium of books, to Captain Douglas Galton, R.E., F.R.S., Assoc. Inst. C.E., for his paper on "Railway Accidents, showing the bearing which existing legislation has upon them."

9. A council premium of books, to Henry Charles Forde, M. Inst. C.E., for his paper on "The Malta and Alexandria Submarine Cable."

10. A council premium of books to Charles William Siemens, F.R.S., Inst. C.E., for his paper "On the Electrical Tests employed during the construction of the Malta and Alexandria Telegraph, and on insulatng and protecting Submarine Cables."

11. A council premium of books, to James Atkinson Longridge, M. Inst. C.E., for his paper on "The Hooghly and the Mutlah."

12. A council premium of Books to James Oldham, M. Inst. C.E., for his paper "On Reclaiming Land from Seas and Estuaries."

STEAM CULTIVATION.

THE application of steam-power to the processes of husbandry is no longer a question of doubt, as it was a few years since, but one of fact; and, so far at least as it has yet been put in practice, it is eminently successful. An interesting scene was to be witnessed at Farningham, on two days of this week, in the competition of several machines, on the rival systems of Smith, Howard, and Fowler. Some explanation of their different principals, and of other steam-cultivating inventions, which were not exhibited on this occasion, may here be given. The Royal Agricultural Society of England, while it had not deemed fit to offer any prizes for a regular match of the mechanical ploughmen, had liberally granted £600 or £700 for the expenses of their working exhibition. The system, however, of Lieutenant Halkett, which is the most elaborate of any, was debarred from this competition by its requiring the costly provision of laying down a set of rail upon the land. Mr. Fowler's twelve-horse-power self-propelling engine, with a four-furrow plough, for which may be substituted a grubbing or a scarifying implement when required, appeared to be a very efficient machine; but equal, if not greater execution, was done by one of Howard's stationary engines at work not far off, although deprived, by an accident disabling its fly-wheel, of a fifth part of its power. Another engine of Howard's worked a drill, by which sack after sack of grain was sown with wonderful rapidity. Meanwhile the powerful machine of Mr. Smith, which is presently to be described, was employed on a neighbouring hill in "smashing up" some heavy ground; the soil where Fowler's and Howard's were ploughing was almost as light and loose as sand. The decision of the judges, which is not yet announced can hardly go far to settle the practical question of using the steam-engine in agricultural operations; for machines are in existence, and others are now being constructed, on principals very different from those shown at Farningham; and the difficulties which have been experienced in em-

ploying steam labourers for the actual business of farming, except on a large scale, may be got over by some improved contrivance.

There is, indeed, good reason for thinking that the ultimate serviceableness of steam-power in husbandry will go far beyond the present limits of its application. In other arts, wherever it is introduced, without one exception it reigns paramount, having superseded every other power. Throughout the whole range of manufacturing industry, it has banished hand-labour in all the more onerous departments, confining it almost exclusively to those in which the exercise of mind is necessary. Thus, in the textile manufactures, steam-power does everything, from the preparation of the material to the perfecting of the fabric; the office of the operative being to watch the movements of the machinery, supply it with materials, regulate its speed, and perform other light operations requiring the use of the judgment. In the workshop of a machinist, likewise, steam-power is used for turning, cutting, filing, polishing, and fitting the different portions of the work in hand. What, then, is there in the nature of land to prevent a similar universal change from being effected by steam-power in agriculture? At present its use is limited in cultivation to the simple operation of ploughing, or otherwise breaking up the soil, whilst four out of five horses which were formerly required are still necessary to perform the other work of the farm. It is evident that steam may be made to do whatever is done by mere brute force.

The different modes of steam cultivation which have been actually put in operation may be divided into three distinct classes, namely, the traction system, the roundabout system (as it is quaintly termed), and the gudeway system.

The *traction* steam-plough was first invented by Boydell, who expended a good fortune upon it. This consisted of a locomotive steam-engine of 10 or 12 horse-power, to the wheels of which were attached "an endless railway," formed of a succession of strong flaps made of wood and iron, so fixed by one end as to fall under the wheel upon the ground as it progressed, and thus to prevent it from sinking into the soil. Three or four ploughs were attached by chains to the engine, which, when in motion, turned up the soil to the depth of from six to ten inches, the furrow-slice being nine or ten inches in width. Each plough required a man to guide it, as the ploughs were connected with the engine only by the chain, and totally unconnected with each other. It was found, however, that the weight of the engine—nine or ten tons—injured the land, and the number of men required to attend upon it rendered it an expensive plan; whilst a heavy shower of rain would stop the work altogether on a clay soil. At any rate, when other more eligible systems were introduced, Boydell gave up the attempt to establish this engine as a cultivating machine, and applied it to the purpose of a traction-engine for drawing heavy weights on the common roads. Boydell was followed by Romaine, who adopted the same system. His machine professes to perform the operation of digging the soil; but the enormous weight of the whole apparatus—no less than fifteen tons,—while it does not carry its own railway like Boydell's, precludes its use on a wet clay soil. Even upon a second year's clover lay, it will sink an inch into the soil; what, then, must it do on a fallow saturated with rain?

The second or "round-about" system includes several different forms, namely, Smith's, Howard's, (which is a modification of Smith's), Fowler's, and another invented by a Jersey farmer, which, as it has not been tried in public, we need not describe. Smith's system is this:—At one corner of a field is placed the steam engine and the windlass or drum, for paying out and receiving the endless rope. On a line with the engine, at or towards the further part of the field, is an *anchor* with a pulley; at the opposite corner to this is another anchor and pulley, and at the third corner another; the three anchors, with the engine, forming a square, about which the endless rope is passed, being wound round the windlass in order to its being acted upon by the steam power. Attached to the rope at the farther end of the square is the *cultivator*, consisting of a strong frame with five strong tines, with broad shares, so placed as that they stir the whole of the soil in their progress. The steam power works the rope by means of the windlass, and draws the cultivator through the soil to the opposite corner, where it is turned round and drawn back again, and so on till the whole square of land is "smashed up," as Mr. Smith expresses it. It is necessary in taking fresh ground to move the anchors forward at every bout. The quantity of land cultivated per day is from four to seven acres, at an expense of from 3s. 6d. to 6s. 6d. per acre.

Howard's system is a modification of Smith's; the improvement he has effected consisting in the working machine being a balance plough or cultivator, with the ploughs or tines pointing in opposite directions, which precludes the necessity of turning round at the end of the furrow, as is the case with Smith's. Some minor improvements have also been made, which it is unnecessary to point out.

Fowler's system has hitherto maintained an ascendancy over every other, and not only gained the prize of £500 from the Royal Agricultural Society, but also the first prizes at almost all the agricultural shows throughout the kingdom, and in France and Belgium. A steam-engine, with a windlass attached, is placed at the corner of a field. Opposite to it, on the other side of the field, is a machine called an anchor, very heavy, with iron wheels, sharpened at the periphery, so as to enter and retain a strong hold of the ground, to stand against the strain of the rope and the ploughs. A large pulley is fixed on this machine, over which the endless rope is passed, and also wound round the windlass attached to the steam-engine. The frame which bears the ploughs, four in number at each end, is balanced in the centre, being formed to an obtuse angle. The ploughs point four each way, so that, when those at one end are in the ground, the others are up in the air. The machine, being made fast to the rope, is drawn through the soil; and when it has arrived at the headland, where the anchor is fixed, the ploughs are lifted out of the ground, and those at the other end take their turn of the work. At each bout, it is necessary for the engine and the anchor to advance a step along the headland, to allow fresh ground for the ploughs. By this means from five to eight acres may be ploughed per day of ten hours, to the depth of from six to nine or more inches, if necessary, at an expense of from 5s. to 8s. or 9s. per acre.

We come next to the Halkett, or guideway system, which differs from all others, and which professes, when fully carried out, to perform every operation of husbandry, from the ploughing of the land to the harvesting of the crop, with the same machine. There are only two forms in which the *guideway* system has appeared; that of Mr. Halkett, the inventor, and that of Mr. Grafton, which is a modification of the other. We may give a brief description of Mr. Halkett's plan.

The guideway is formed by laying down the whole of the land with permanent rails, similar to those of the common railway, only with fifty feet or more distance between them. The rails reach across the field, and at one of the headlands rails are laid down at right angles to the working ones, and low enough for the working platform to run upon a shunting apparatus, by which it may be moved to a fresh set of rails, or to another field, or taken home, as may be desired.

The working platform or machine consists of a strong framework of timber and iron, extending across the intervals and resting upon the rails at each end, with eight low wheels. This machine is strongly braced together, so as to bear any strain that may be put upon it in cultivating to any required depth. Mr. Halkett, in fact, has cultivated to the depth of 25 inches. At each end of the platform is fixed a small steam-engine, say of four or five horse power, geared together by an intermediate shaft, so as to act simultaneously upon the wheels, which are driving as well as bearing ones. The engines are firmly fixed to the platform, and the power is communicated to the wheels by the same machinery of cog-wheels, pinions, and rods, as in other cases.

The implements of husbandry of any kind may be attached to the under part of the platform, which can be raised or depressed according to the work required. As many as twelve ploughs, or even more, may be worked at once by this means; but double the number worked at once are required, so that half are lifted whilst the other half are at work. When the whole space between one set of rails is ploughed or otherwise tilled, the platform is run upon the cross-rails and shunted to the next set; and so on, till the whole field is finished.

On Mr. Halkett's own land at Wandsworth, various agricultural operations were successfully performed by this machinery—namely, ploughing, sub-soiling, harrowing, rolling, clod-crushing, drilling seed (either dry or with liquid manure), hoeing, scarifying, watering crops (either on or below the surface), cleaning and comminuting the soil with the Norwegian harrow, carting and distributing farm-yard or artificial manure, reaping, mowing, and carting crops of corn, roots, and hay. All these different processes were wholly performed without the intervention of horse-power or of hand labour, except where the exercise of *mind* was required. There was, therefore, no pressure on the land of the foot of man or beast, or of wheel carriages, except in going over it for such purposes as pulling up roots, making hay, and tying up sheaves of corn.

The manifest advantages attending this system are,—precision of operation, economy of time and labour, concentration of power, perfection of work, and universality of operation. When once the implement, of what ever kind, is fixed to the machine, it cannot deviate from the direct line, so that in hoeing, for instance, the hoes may be set to cut within an inch of a row of plants, which they will never touch, because the seed, having been drilled by the machine, lies in a perfectly straight line parallel with the rails, which keep the hoes in the same direction. The machine, too, can, on a stress of work, be employed day and night in ploughing or any other operation, which is an important advantage, realised in every other industrial employment, but hitherto rarely taken into account in agriculture. To this system the only objection to it is the expense (£20 per acre) which at present appears to bar its adoption.

A new cultivating machine, however, on the locomotive principle, is now being constructed by Mr. Bray, the inventor of the well-known traction engine used upon the high roads. If Bray's contrivance for applying steam power to agriculture does what it promises, it will be a most valuable boon to the occupiers of moderate-sized farms. His engine, about six feet wide and eight long, is compact in form, and weighs, together with the apparatus for ploughing, not more than about three tons. This will do the work of eight horses, and never tire. It does not require to have rails laid for it. It can be worked by two men and a boy with ease, and they may ride afield on the top of the frames, to which the implements are fixed, on either side of the axle. Though it will turn with the greatest facility, it need not, in ploughing, be turned round at the end of the furrow, as it will plough backwards and forwards. The apparatus and engine described will plough three furrows at once, and may be adjusted to cut them of such depth and width as the nature of the soil requires. The same engine can be put to draw a loaded waggon, to thrash corn, to work a hose for distributing liquid manure, and to do many other things for the farmer, who may sell two team of horses and save their keep, when he has secured the services of such a powerful labourer as this. From its lightness, it will avoid the great objection to Boydell's steam-ploughing machine on the traction system.—*London Review.*

KNOWELDEN'S PATENT PUMPS.

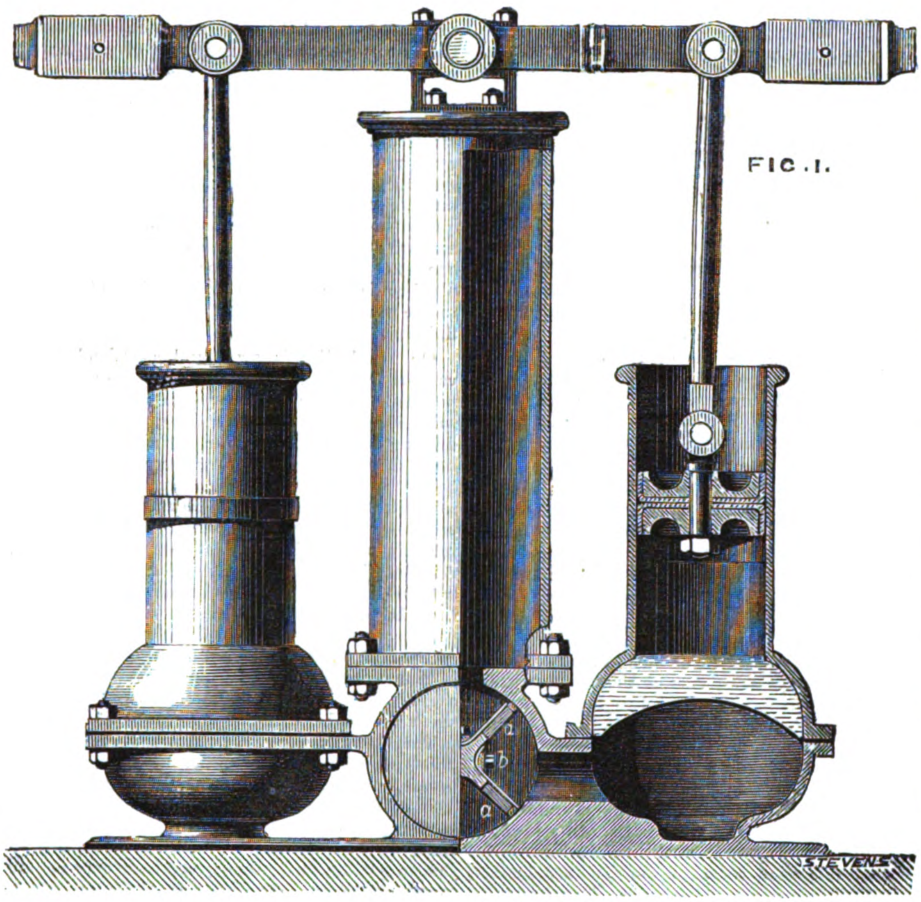

FIG. 1.

MR. J. KNOWELDEN, of Southwark, has just patented an improvement in pumps. These improvements are based upon an invention patented in 1859, and illustrated in our columns 20 Jan., 1860. The first part of this invention refers to the valve chamber and valves; it consists in forming the chamber circular, and in fitting the valves to feathers on a circular plug. The patentee connects a handle to the outside of the plug, whereby the same may be withdrawn in case of need, and whereby the action of the pumps in connection with the valves may be reversed, that is, the pipe which acted as a suction pipe may be made to act as a force or delivery pipe, and that which acted as a force may be converted into a suction pipe. Fig. 1 of the accompanying engravings is a side elevation partly in section; and Fig. 2, a detached view of one of the plugs of a pump fitted with valves; *a a* are the valves fitted in a circular box or chamber *b*; *c c* are the valve feathers. The valve rod extends outside the box, and is fitted with a handle whereby the position of the valves may be altered and the action of the pump consequently reversed. No fastening being required to hold the valves, they may be withdrawn, any impediment to their action removed, and they may be immediately replaced in the valve chamber. Water, which is alternately drawn into the compartments, and through the apertures formed in the lower part of the valves, is forced through the action of the pistons and diaphragms into the chamber *g* through the apertures in the upper part of the valves.

The invention further consists in making the pumps for donkey engines double-acting. The plunger is formed with a space in the bottom, to which a valve is fitted; and on the bottom of the plunger a piston is secured of the same diameter as the bore of the barrel. A valve may or may not be in the bottom of the barrel.

FIG. 2.

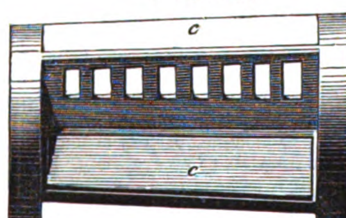

Fig. 3 is a section of so much of a donkey engine as will be necessary to show the manner in which pumps are rendered double-acting; *a* is the steam cylinder, *b* is its piston, and *c* the piston-rod united to the cross-head *d*, which is free to slide up and down in guides *e e*; *f* is the piston in the pump *g*; a space is formed in the lower part of the piston for holding a valve at its upper part; *k* is the plunger, having an annular space between it and the pump barrel; *l* is a valve at the top, and *m* is a valve at the bottom of the pump, the former in the outlet pipe, and the latter in the inlet. Supposing water to be drawn into the pump by the pipe *m*, and the piston to be at the top of its stroke, then on its return stroke half the water thus drawn in will be delivered through the outlet pipe, and on the up stroke the other half will be delivered through the same pipe, and so on.

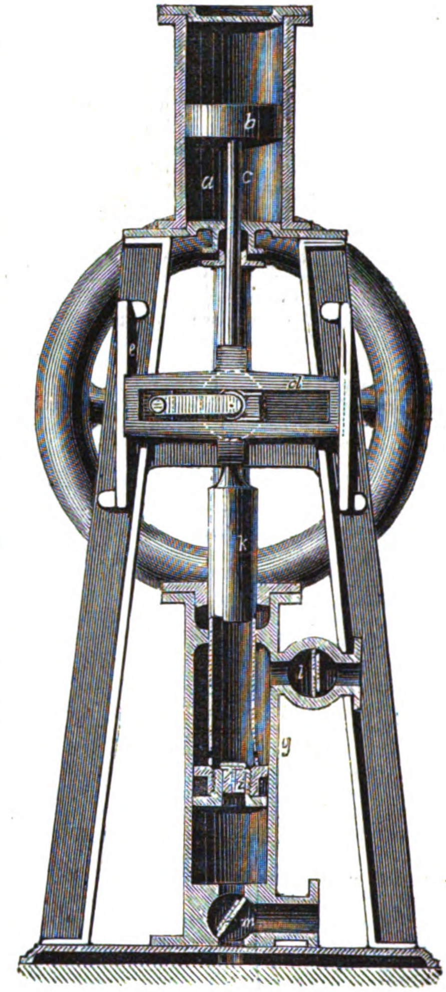
The invention also relates to constructing pumps for working presses and other purposes, to be worked by a steam cylinder or otherwise. The pumps are placed in direct connection with the piston-rod, and the valve motion is so constructed that the engine shall be stopped when the pressure exceeds the working pressure of the pumps. The pumps are made double-acting by fitting them with four valves; the barrel of the pump is bored

FIG. 3.



and fitted with a piston, which is fitted on the end of a plunger of so much smaller diameter than the barrel as will leave sufficient space to form the pressure side of the pump.

Fig. 4 is a side elevation partly in section, and Fig. 5 is an end view of a pump for working presses; *a* is the cylinder, *b* the piston, and *c* the piston-rod which also forms the plunger to the pump *d*. The valves of the cylinder are worked by the small cylinder *e*, which carries a lever *f* extending down to the piston-rod *c* below; stops are placed on the piston-rod. At each stroke of the piston these stops come against the lever *f*, and thereby open and close the ports in the steam cylinder; *h h* are valves—one is in communication with the pressure side, and the other with the speed side *k* of the piston. When the valve rises by the pressure exerted upon it to near the upper end of the spring on the valve, by means of levers it closes the cock by which steam is admitted to the cylinder and stops the motion.

In working pumps for extinguishing fires and other purposes, they are made with a variable stroke, in order to their being effectually worked under high and low pressure.

The following gentlemen have had medals awarded to them for papers read before the Society of Arts:—Dr. F. Crace Calvert, F.R.S., for his paper "On Improvements and Progress in Dyeing and Calico-Printing since 1851." The Society's Silver Medal. E. C. C. Stanford, for his paper "On the Economic Uses of Seaweed." The Society's Silver Medal. James Morris, for his paper "On Mauritius: its Commercial and Social Bearings." The Society's Silver Medal.

KNOWELDEN'S PATENT PUMPS.

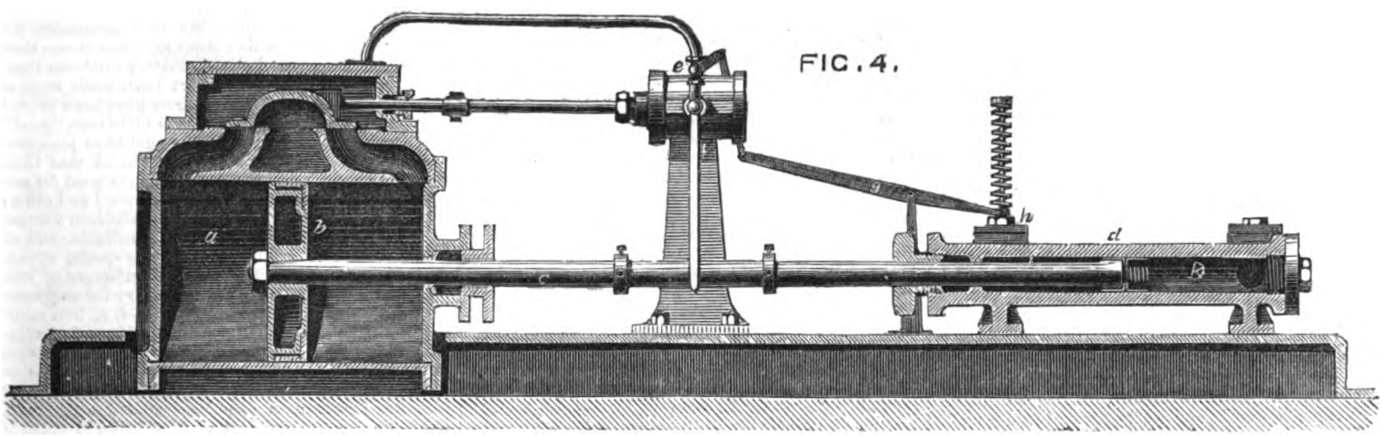


FIG. 5.

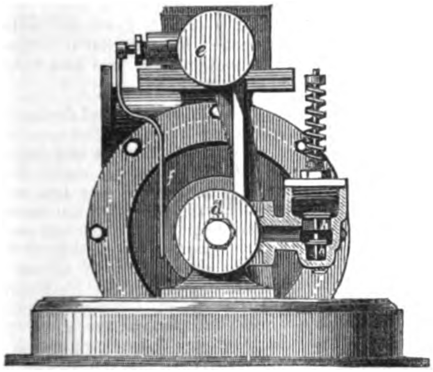

ON THE CLEANING AND PRESERVATION OF ENGRAVINGS.

AUGUSTUS A. HAYES, M.D., State Assayer of Massachusetts, says in the *Scientific American*:—

The frequent inquiries addressed to me by those who possess valuable engravings—which have become damaged through accident, or exposure—respecting a mode I adopted successfully for restoring some very fine ones, induce me to publish a general process applicable to the largest number of cases.

Any one who will incur the trouble of looking up in the older print shops, and depositories in residences in this country, will find abundance of defaced engravings of rare merit—the works of the best masters rejected, which can be restored easily to quite their former degree of freshness and beauty. All who have studied the better efforts of the old artists, in giving permanency to their conceptions in this department of art, assign to it a very high place, and it may be suggested that a higher cultivation and enjoyment of design and execution, in so far as the influences of light are concerned, may be gained from careful observation of engravings, than can result from time bestowed on paintings, which often command public admiration, or are the so-called gems of an exhibition.

In commencing to restore an engraving some attention must be given to the kind of injury it has suffered. A general brown colour, more or less deep, resulting from atmospheric action only, is the least possible change. Spots and stains caused by ink, coloured fluids, oil or insects, must be first treated and all pencil marks removed by india-rubber or bread crumbs. A fluid acid, obtained by dissolving one ounce of crystals of oxalic acid in one-fourth of a pint of warm water, may be used for application to all stains, and the paper should be wet with it thoroughly where spots of any kind exist. Excepting in a few cases, this acid will not cause the removal of stains immediately, but generally it combines with the bases of them, and they are removed by subsequent steps; the thorough wetting should be done a few hours before proceeding to clean the engraving.

To facilitate handling and for the protection of the edges of the paper, a piece of millinet, or the stiff open fabric formerly sold for ladies' skirts, should be roughly sewed around one stick at each end, so as to form an apron, like a chart attached to two rollers, the cloth of which must be an inch larger than the largest print to be handled. From one to ten prints of even large size may be cleaned at one time, after they have been wet on their spotted parts with the acid, and evenly spread on the apron, so as to allow of the immersion of the whole in water. A tub of the ordinary size will allow prints of considerable surface to become immersed, but the most desirable resort is a common bathing vessel, so nearly filled with warm water that the bent paper supported by the open texture can rest on the bottom and sides, where it should be allowed to remain with occasional raising of it, and moving it by means of the stick handles, from twelve to twenty-four hours.

On the first trial a degree of alarm will be felt in the case of a highly-prized favourite, at this seemingly careless treatment; but it must be borne in mind that paper is a firmly felted mass of short fibres which may be soaked in various fluids for weeks and resist all diluted acids and most chemical agents for a long time wet, if not exposed to mechanical abrasion by touch or rapid motion. The strong paper of engravings absorbs much air, which resists the penetration of the water, and motion is necessay to remove this as well as to allow the coloured solutions formed to pass away. This motion may be given by holding the supporting sticks and passing the mass from end to end of the bath, or slowly up and quickly down, enabling the sheets to become separated momentarily. Discoloured water may be drawn off, the apron and contents resting on the bottom and sides, and fresh water be slowly admitted to replace it. Cold water can be substituted for warm, longer time being allowed for its action. When the prints no longer add colour to the water after being agitated, the water must be withdrawn and replaced by such a portion as will barely cover the paper. Half a pound of bleaching powder (chloride of lime) mixed to a paste first in cold water, and then added to two quarts of cold water and well stirred from time to time for six hours, will afford a nearly clear fluid resting on a white deposit in the earthenware vessel. A portion of the clear part of this fluid must be added to the water in the bath, until both taste and odour denote the presence of chlorine in the water. Motion being given to the paper the bleaching effect of chlorine will be preceived, or its odour in the water will have been lost; when more must be added so that the odour or taste of chlorine must be present in the water two or three hours.

The action of the chlorine on the parts previously wet with the acid will remove nearly every kind of discoloration, while the brown hue of the paper giving place to perfect whiteness, the light and shadows of the engraving become of their original perfectness, and the picture will be as distinct as when it was first impressed. It has happened, in a few trials, when the prints were long stained they did not yield to the weak chlorine water, that resort was to have a little mineral acid to develop free chlorine in the bath. One ounce of muriatic acid was added to one pint of cold water, and the weak acid thus formed mixed in the water of the bath, soon caused the bleaching of every fibre in the paper.

After the bleaching the water must be drawn off, the paper drained, fresh clear water admitted, and the paper moved through the water to thoroughly wash away all adhering chlorine. Several quantities of water may be used, the paper being each time drained; and finally the whole mass, raised by the handles, may be placed on a clean white wood table or board to drain. If a number of prints have been treated, the wet mass may be placed in a warm room, or air may be admitted, and as the one on the top of the pile becomes more dry than the rest, it may be removed to any support and left to dry. In hastening the drying I have extended ordinary bed sheets and spread the wet prints singly on these; slow drying rendering any pressing unnecessary.

Those having the usual presses might prefer to press the still damp sheets, and where only two or three prints are the subjects of trial the substitution of other vessels and ready appliances will occur to any one.

This discription is given in detail purposely, although unnecessary, so far as the process is concerned, because I wish to impress on the mind of any one who possesses an injured engraving, that it can be restored to its original value without the expenditure of much attention; and it must not be the conclusion, from reading this process, that great care is required, for time is insisted on rather than attention. The few dispositions being made, not the slightest care need be given to the matter; if the bath can be spared, the odd minutes of a week will enable one to restore dozens of specimens and give permanency to their beauties.

INTERNATIONAL EXHIBITION.

CLASS I.

IT is announced in the Official Catalogue that Class I. embraces "mining, quarrying, metallurgy, and mineral products." These products consist essentially of materials of construction, such as building-stones, slates, marbles, clays, &c.—of substances employed as fuel or for the production of light, such as peat, coal, and mineral oils,—and of ores yielding metals. The official classification is not strictly scientific, for, obviously, ores should precede metallurgy, which is the art of extracting metals from their ores, and adapting them for immediate use by the various workers in metals. But it is not material in what order the divisions of this great class are considered, and we shall begin with metallurgy. However,

before preceeding, we feel constrained to offer a few remarks on the treatment which Class I. of the British Department has received at the hands of Her Majesty's Commissioners. It is certain that great Britain has mainly derived her wealth from her vast subterranean treasury of coal and iron ore; and in no other part of the world are such prodigious amounts of coal raised and iron produced. The smelting of copper, lead, tin, and silver is also conducted on a very extensive scale in this country. It might, therefore, have been anticipated that Class I. would at least have been respectably accommodated; but, we regret to add, the reverse is the fact. Places of honour in the most conspicuous part of the building have been assigned in some instances to unsightly agglomerations of comparative trash, while the true and substantial representatives of British power and wealth have, for the most part, been doomed to a narrow passage leading to an out-house! The arrangement, moreover, of this class is sadly defective; but this, no doubt, is to be attributed to the limited space at the disposal of the superintendent. The classification, also, is in some respects unintelligible. Thus, the production of steel is essentially a metallurgical operation, and, therefore, belongs to Class I.; yet Krupp, Bessemer, and others, are excluded from it.

The metal which we propose first to consider is iron. But what is iron? This is a question which few persons would hesitate to answer; yet it is one which few could answer properly. The most familiar things are often the least understood, and of these, iron is certainly one. Pure iron is almost unknown, and, probably, not half-a-dozen men now living have ever seen it. What we call iron is the metal combined or associated with other elements, which, though present only in small quantity, may, according to their number and proportion, communicate to it widely different properties. These elements are chiefly carbon, silicon, sulphur, and phosphorus; but the most important is carbon. It is a simple variation in the proportion of carbon, within the limit of about five per cent., which causes the metal to appear in the three well-known states of wrought iron, steel, and cast-iron. As the proportion of carbon increases, the metal passes insensibly through these successive stages. We should, however, remark that it has recently been urged that another element, nitrogen, is an essential constituent of steel; but this theory has been hotly disputed last year in the French Academy. We have maturely weighed the evidence advanced on both sides, and have come to that conclusion that nitrogen is not essential to, but is often present in steel, and may sensibly affect its qualities. With regard to the other three of the four elements above mentioned, it suffices to state, that sulphur is the most frequent cause of *red-shortness*, and phosphorus of *cold-shortness* in wrought-iron. Now, when we reflect that one part in a thousand of any one of these elements will produce a decided effect on the quality of the iron, either separately or combined; and, when we further reflect that the proportion, in which each may be present is subject to considerable variation, we may readily conceive how great must be the diversity in quality of the iron, steel and pig iron, which we meet with in commerce. Then, again, in the case of wrought iron and steel the quality of the metal may be greatly modified by the mechanical treatment which it has received; and in the case of pig iron by the conditions under which solidification after fusion has occurred. It is a remarkable fact that, so far as our knowledge extends, iron is the only metal which is capable of acquiring such varied and useful properties by the operation of such simple and apparently trivial causes as those which we have just considered. One metal is thus made to act the part of several. The defective state of our knowledge of the chemistry of iron is the opprobrium of modern chemists. A thousand problems of the highest interest, relating to this all-important metal, await investigation; and we affirm, without fear of contradiction, that there is no metal of which the *science*, properly so-called, is less understood.

In the British Department there is no general collection of British iron ores such as Mr. S. H. Blackwell, of Dudley, presented in the Great Exhibition of 1851. That remarkable and instructive collection required for its formation not only extensive knowledge, but considerable personal devotion; and we doubt whether the valuable services which Mr. Blackwell then conferred on his country have ever been duly appreciated. It is preserved in the Museum of Practical Geology, where, unfortunately it is only dimly visible. But, while there is no general collection, there are numerous and excellent illustrations of the iron ores of particular districts, of which many are exhibited in juxta-position with the products derived from them. The red hæmatites, or, as they are technically termed, the "red ores" of Cumberland and Lancashire are well represented. There are two distinct varieties of these important ores—the hard and the soft. The latter are the most prized, as the former yield pig iron rich in silicon, which wastes considerably in puddling. It is generally admitted that iron derived exclusively from hæmatite ores is more or less red-short, but no satisfactory cause has yet been assigned for the fact. There are specimens of brown hæmatite from the Forest of Dean; and of these we would direct attention to the fine mass of "Black brush" ore, No. 76, which is interesting from the circumstance that it represents, as we are informed, a conquest of no ordinary kind over mining difficulties arising from water. Brown iron ore occurs in various localities in Great Britain, among which we may mention Cornwall, Devonshire, South Wales, and North Staffordshire. One of the best and purest varieties we have ever seen is the Frog-hall ore, from the last-named district.

The Ebbw Vale Iron Company displays fine specimens of sparry iron ore, or spathose carbonate of iron, from the Brendon-hills, Somersetshire; and the Weardale Company large masses of the same kind of ore from their mines in Cumberland. One peculiarity of this beautiful ore is, that it contains a large proportion of carbonate of manganese; it is exclusively this ore which furnishes the variety of pig-iron known as "Spiegeleisen," so called from the large, brilliant, mirror-like planes, which appear on its fractured surface. This remarkable variety of pig-iron is in special request for steel making, and magnificent specimens of it will be found in the Zollverein Department. Next in order follow the impure and earthy carbonates of iron, known as clay or argillaceous iron ores. It is this class of ores which has hitherto constituted the chief part of the mineral wealth of England. They occur abundantly and with great regularity in our coal measures in Yorkshire, Derbyshire, Staffordshire, Shropshire, and Wales. They are not confined to these measures, and are met with in various geological formations, even as high as the Tertiaries. When clay-iron ores contain much coaly matter they are termed "black band" ores, and it is these ores which have mainly created the wealth of the Scotch ironmasters. The late Mr. Mushet first discovered their value about the beginning of the present century. The Scottish ironmasters exhibit a remarkably fine and instructive series of these ores, No. 318. The "black band" is not confined to Scotland, but occurs also in Wales and North Staffordshire. A large mass from the well-known bed termed "Red Mine," in the last-mentioned district, is shown in No. 125. Specimens of various clay-iron ores will be found accompanying several of the collections of iron, but among them there is nothing to demand particular notice, except, perhaps, the utter worthlessness of some, if really intended as practical illustrations.

The vast deposits of iron ore occurring in the lias of Yorkshire is well illustrated by large and characteristic specimens. The discovery of this ore is of recent date, and, if we mistake not, Messrs. Bolckow and Vaughan were the first to recognize its importance, about the year 1847. They speedily erected blast-furnaces, and other ironmasters were not slow to follow their example; and now North Yorkshire has become one of the largest iron-producing districts of Great Britain. The ore in some localities is marvellously abundant, and can be raised at a very small cost. It is smelted with coke obtained from Durham, and, notwithstanding, the forge-pigs made from it can be sold with profit at £2 7s. per ton. We have heard some of the great Welsh ironmasters, after a visit to Cleveland, express considerable apprehension concerning their fate. The ore has a dark greenish, or bluish gray colour, and consists essentially of carbonate, in admixture with some silicate, of iron. Happily, some of the older iron-making districts can yet maintain a successful competition with the furnaces of Cleveland and the vicinity as to the quality of iron. A large block of ore from Rosedale, in the north court of the Eastern Annex, is well deserving of inspection. This variety of ore is magnetic.

It is only during the last twelve years that the extensive deposits of oolitic ores in Northamptonshire have been developed, chiefly through the instrumentality of Mr. S. H. Blackwell, who exhibited a few specimens of them in his collection at the last Exhibition. They are sufficiently represented in the present Exhibition. They consist for the most part of earthy brown hæmatite, and vary much in composition. They not unfrequently contain much phosphoric acid, and in that case yield pig iron, rich in phosphorus, which is unsuitable for many purposes, though it may be well adapted for castings in which strength is not required. These ores, which can be raised at a low price, have been largely consumed in certain well-known iron-making districts, and have assuredly not contributed to maintain, much less to enhance, the high reputation for good quality of iron which these localities at one time deserved. We do not indiscriminately condemn these ores; but we venture to assert that, while some of them may be tolerably good, others have been proved to be decidedly bad. We use these adjectives, "good" and "bad," with reference to the quality of iron produced, and it is necessary to bear in mind that their meaning is only relative. Iron which is good for one purpose is bad for another; but engineers and others are apt to employ these terms in too absolute a sense, and pronounce all iron good which is suitable, and all iron bad which is unsuitable, for some special object. A word on specifications for the manufacture of iron may here be in season. It is customary for engineers to prescribe that "mine iron" only—*i. e.*, iron made entirely from ores—shall be employed, to the exclusion of the so-called "cinder iron." We have seen many specifications, and we do not remember one in which this proviso has not been inserted; and there now lies before us a recent specification for rails, issued by one of our largest companies, in which is the following clause:—"The puddled bars to be made from mine iron only, without any admixture whatever of cinder iron" (Feb. 24, 1860). Now, it is certain that ores might be selected which would yield iron far inferior in quality even to the worst cinder iron, and we would therefore suggest that it is expedient to enumerate in specifications the ores which may and may not be employed.

Iron ore is obtained from the green sand formation in Wiltshire, where it is smelted. The furnaces are of recent construction. We have heard it maintained by a practical ironmaster of great experience that iron may be made in this district at a very low cost. The ore consists essentially of earthy brown hæmatite, and contains a large amount of siliceous sand, which would certainly not improve the quality of the pig-iron produced, unless the presence of silicon be regarded as advantageous! A neat and instructive series of specimens of the ore and furnace products, accompanied by a sectional plan of the workings, is exhibited by the Westbury Iron Company, No. 130.

It must not be supposed that we have passed in review all our workable iron ores. Extensive beds of clay-iron ore occur in Sussex, which in former times was one of the chief iron-making districts of this country. Our tertiary beds also contain clay-iron ore; and large quantities of this ore have been dredged up by fishermen off the coast of the Isle of Wight, and shipped to Cardiff, where it was sold at 10s. per ton in 1859. Ireland would be able to supply a large amount of iron ore if the expense of inland carriage were not, as at present, an insuperable obstacle to its transport. The conditions under which the smelting and manufacture of iron are now conducted in this country have been greatly modified of late by increased facilities of conveyance both by land and sea. Iron ores have been extensively carried from one part of the kingdom to the other, and have even been largely imported from the north-west coast of Spain. The manager of one of the greatest ironworks in South Wales recently informed us that they could procure good ore from Spain more cheaply than from a neighbouring county in England. One result of this interchange of ores has been in some localities to deteriorate, and in others to improve, the quality of the iron produced. In certain districts which had at one time a high reputation for quality, good ore has been purposely adulterated with bad on account of its cheapness, in the hope of competing successfully with other districts which have the power of making cheap, though not good iron. We have reason to know that not a few of our ironmasters now admit that, in some instances at least, this policy has proved a commercial blunder. Well-established reputations have been too hastily sacrificed, which it will require many years to restore. Yet some ironmasters have set to work in right earnest to amend their course, and we earnestly wish them success. The ironmaster may learn much from the present Exhibition. Ores are brought together from all parts of the world, and exhibited in association with the products which they furnish. A means of comparison is thus afforded which, we believe, is in the highest degree advantageous to all, whether British or foreign, who are engaged in the smelting or manufacture of iron. The public also may learn much by a careful inspection of the objects shown in Class I., and in our future communications we shall direct attention to every article of particular interest.

THE IDENTITY OF PERCUSSION FORCE AND MOMENTUM.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—It would be well to understand each other upon the above subject. Those of your readers who have not Bourne's book upon the "Screw Propeller" may be glad to see his explanation of the matter, which, I believe, is generally accepted.

"Mechanical power is pressure acting through space; and the amount of mechanical power developed by any combination is measurable by the amount of the pressure, multiplied by the amount of space through which the pressure acts. A pressure of 10 lbs., acting through a space of 1 foot, represents the same amount of mechanical power as a pressure of 1 lb. acting through a space of 10 feet; and 10 lbs. gravitating through 1 foot, or 1 lb. gravitating through 10 feet, represents ten times the amount of mechanical power due to the gravitation of 1 lb. through 1 foot. In the same way, 1,000 lbs. gravitating through 1 foot is equivalent to 1 lb. gravitating through 1,000 feet; and, in general terms, the weight or pressure multiplied by the space through which it acts represents the power universally. If, therefore, a body falls freely through space by the operation of gravity, since it parts with none of its power during its descent, the whole power must be accumulated in the falling body in the shape of momentum, and, at the instant of reaching the ground, the body must have such an amount of mechanical power stored up in it as would suffice to carry it up again to the position from which it fell, if the power were directed to the accomplishment of that object. The amount of mechanical power, therefore, in any moving body is measurable by the weight of the body, multiplied by the space through which it must have fallen by gravity, to acquire the velocity it possesses; and this fundamental law, if distinctly apprehended, and kept constantly in recollection, will ensure exemption from the fallacies which prevail so generally among English authors in reference to such subjects. In Newton's 'Second Law of Motion,' it is maintained that 'the change or alteration of motion produced in a body by the action of any external force is always proportional to that force,' whence it is inferred that to produce twice the quantity of motion in a body will require just twice the power; and this is the doctrine maintained by Robinson in his 'Mechanical Philosophy,' and by Hutton, Gregory, and most other English authors who have undertaken to illustrate such questions. Nevertheless, there is no doubt whatever that the doctrine, though resting on the authority of Newton, is altogether erroneous, as was shown by Leibnitz at the time of its promulgation, and subsequently by Smeaton, who, by a series of carefully executed experiments, proved very clearly that it required four times the amount of mechanical power to double the velocity of a moving body that was necessary to put it into motion at first, and, consequently, that the momentum of moving bodies of the same weight varies as the squares of their respective velocities. The soundness of this conclusion is made manifest by a reference to the law of falling bodies, by which it will be found that it is necessary a body should fall through four times the height to double its ultimate speed, nine times the height to treble its ultimate speed, and so on, showing that the height, and, therefore, the power exerted in creating the motion, must be as the square of the ultimate speed, and, consequently, that the ultimate velocities of all falling bodies will be as the square roots of the heights from which they have respectively descended. In the case of two bodies of equal weight, therefore, moving in space, but of which one moves with twice the velocity of the other, the faster will have four times the amount of mechanical power stored up in it that is possessed by the slower, for it must have fallen from four times the height to acquire its doubled velocity; and the relative quantities of power capable of being exerted by bodies of the same weight, is measurable in all cases by the spaces through which the weight or pressure acts. A cannon ball, moving with a velocity of 2,000 feet a second, has four times the momentum of a cannon all of equal weight moving with a velocity of 1,000 feet a second."—Pp. 95, 96.

JOHN HARVEY, Capt. R.N.

Cheltenham, June 26.

CONCUSSION SHELLS AND NAVAL WARFARE.

SIR,—Having lately had occasion to refer to a file of newspapers of the year 1843, I happened to observe under the above heading, in the *Standard* of the 6th June, the following statements:—

"In the course of practice with Captain Norton's concussion shells at Woolwich, at the respective ranges of 1,250, 800, 600, and 400 yards, it was found that the shells exploded between the two bulkheads, placed 12 feet asunder, thus proving what formidable engines they are for naval warfare."

This is not only interesting, but important, inasmuch as it fixes conclusively the date at which the late General Chalmers, R.A. (at that time Captain, and Secretary to the "Select Committee"), announced that the result of the above trials was "so thoroughly satisfactory in every way," that the Committee had resolved to recommend the inventor, Captain Norton, to Government, for the ordnance pension of £500 a year.

I happen to know that the recommendation was duly forwarded, and yet from that time to the present —a period of *nineteen years*!—not one farthing has this gallant veteran received, either for this or for any other of his many most ingenious and valuable inventions, to the perfection of which he has devoted his fortune and his life. Yours, &c.,

HANS BUSK, Captain V. Rifles.

United University Club, July, 1862.

THE STRAIGHT LINE *VERSUS* THE WAVE LINE FOR VESSELS.

SIR,—I am quite willing to wait for the development of Mr. Cheverton's scheme for shipbuilding, and I do hope he will favour your readers with diagrams, so that something definite may be shown, and that his ship may merge out of the region of "day dreams," and at least take its place among "paper inventions."

Every man who has studied mechanics knows that it is not advisable to put matter at rest into *sudden motion*. It is quite possible to connect a steam-engine piston with its work in such a manner as to give the piston *uniform motion* from end to end of the cylinder, but no engineer in his senses would propose such a thing, for the simple reason that his machinery would be *jerked* to pieces. This uniformity of motion, so much desired by Mr. Cheverton, necessitates the *sudden* and momentary overcoming of the *vis inertiæ*; and, even if any advantages did accrue to this uniformity of motion, during motion, the inseparable *jerks* from a state of rest and to a state of rest, would form an insuperable objection to its adoption.

Now I say positively, that water is not an exception in this respect. Uniformity of motion is very well in itself, and *if* Mr. C. can attain it in the case of water without the drawbacks I have above mentioned, then I can only say he knows a form of vessel which was never before conceived, and the sooner he brings it out the better. What is commonly known as the straight line bow has hitherto in practice given very unfavourable results in comparison with the wave line form. In some important experiments with vessels 70 feet long, the straight line bow was very inferior to the wave line, but superior to the convex parabolic form.

If Mr. Cheverton will give definite answers to definite questions it will greatly simplify discussion, and I must request him in his next to say *what angle* of bow he prefers. I am, Sir,

Your obedient servant,

T. MOY.

1 Clifford's Inn, June 9, 1862.

ON THE USES OF CARBOLIC ACID FOR ENGINEERS.

SIR,—Most persons have by this time heard that there is such a substance as carbolic acid; comparatively few have seen it, fewer still have used it, and no one (so far as I can find) has yet noticed a very remarkable property which it possesses in relation to practical mechanics. For the information of those to whom the substance itself is unknown, a word or two will be sufficient to introduce it to their notice. Carbolic acid is one of the products of the destructive distillation of coal, and till within a few years vast quantities of it were utterly wasted. When perfectly pure it is a white crystalline solid, which by absorbing water soon changes into a colourless refractive liquid, having a faint odour of roses and tar. It is not an acid in the popular sense, not being either sour or corrosive, and should therefore, perhaps, be generally designated by its other title of phenole. Crude carbolic acid may be obtained in bulk for about a shilling a gallon, and is a dark tarry liquid, containing, perhaps, from ten to twenty different substances, in a state of mechanical admixture. Fortunately, this crude acid is available for the purposes to which I invite the attention of your readers. Just as oil is an *anti-frictional* liquid, so is phenole *pro-frictional*; or, to state it more correctly, as oil appears to keep surfaces in motion asunder by interposing a thin film between them, so phenole appears to make them *bite* and bind, by bringing them into absolute contact (after a manner of speaking), and removing even the finest film from between them. Any one may convince himself of this by placing a little upon a perfectly clean and dry oil-stone, and then rubbing up the face of a broad chisel upon it. The sensation of the bite (I know of no other word to express it) is very curious, and renders any further explanation unnecessary; it seems as if the stone and the steel had absolutely nothing between them, or even as if they were positively brought together by some attractive force. I have applied this property of carbolic acid to the following operations—grinding, filing, boring, and sawing in metal, with great apparent advantage. When dissolved in fifteen parts by measure of methylated alcohol, it forms a milk-white emulsion if poured into water, and it may be worth while to ascertain whether such carbolated water would facilitate the ordinary work of the grindstone, a point on which I am not able to speak with certainty. If any of your readers should experience, as I did, much difficulty in obtaining the crude carbolic acid, I shall have much pleasure in indicating the source from whence mine was derived, or in supplying any practical engineer with a small sample so long as my little quantity holds out.

I am, sir, your obedient servant,

JOHN EYRE ASHBY, LL.D.

Enfield, Middlesex, July 7th.

THE LATE GREAT FIRE IN LONDON.

SIR,—I wish to explain the reason why this fire raged with such intensity, as a similar fire might happen again. Saltpetre will not burn, belonging to that class termed incombustible salts. It contains, it is true, a very large quantity of oxygen, which it readily imparts to heated combustibles, with which it is in contact. Thus, if we throw a portion on burning coal (a hint that should not be lost on captains of oceanic steamers) the combustion will be brilliant and rapid, and the heat most intense, because the saltpetre supplies the coals with oxygen more abundantly than they could obtain from the air. The product of the combustion, however, will not be altered, carbonic acid gas or fixed air being disengaged in either case. The same remark applies to the salts of manganese.

Let me give a useful *warning* to insurance companies and others, to take every precaution with such a dangerous article as lampblack. There is no article so subject to spontaneous combustion, and it is usually stored in shops with other dangerous combustibles.

I am, Sir, your obedient Servant,

JAMES BRUCE.

June, 1862.

IRON ARMOUR-PLATED SHIPS AND LARGE GUNS.

SIR,—I have read with great interest the accounts in the papers respecting iron armour-plated ships and large guns.

During the discussion on national defences at the Institution of Civil Engineers some time ago, I said that it was idle to talk of invulnerable ships till we knew the power of artillery; that up to that time we had never seen a really large gun. The results lately obtained have justified my words, and I again repeat them as applicable to the present moment.

I will undertake to make a gun which will throw a fifteen-inch rifled bolt with a velocity of 1,600 feet per second. Such a gun, in a Cole's shield, and a proper gun-boat, would demolish either land batteries or iron-plated ships. Speed is not required—such gun-boats would not need to run away. They would steam slowly and steadily up to any fort, or place themselves along side of any attacking vessel if used as defences. One shot would do the work.

Such guns and such vessels will be made, and the sooner our Government tries them, the sooner will the country escape the present monstrous expenditure, and be in a true condition of defence.

I am, Sir, your obedient servant,

JAS. A. LONGRIDGE.

PUNCHING PLATES.

SIR,—"A Civilian" observes in your impression of the 27th ult. that I no doubt "succeeded in punching *a* 1¼ inch hole in a 1¼ inch plate, but this must have strained the machine, and was a *tour de force*." I beg to say that it was nothing, of the sort; for instead of *one*, or, as he has it,

"a 1¼ inch hole in a 1¼ inch plate" being punched by that press, it punched some *thousand or so* of that diameter through plates of that thickness, *without the slightest damage* either to punch or press, nor was the bolster used widely coned either. The punches had the ordinary flat face, and centre punches also were used according to fancy.

I do not in any way "admit" that I "broke a machine" in punching the 1¼ inch hole in the 1¼ inch plate; what occurred was the *straining*, not the "breaking" of the press, which I should have said was not so strong or heavy as the other; and I may add that this self same press is now at work on ordinary work, precisely in the same condition as it was when we ceased experimenting with it.

Yours obediently, C. F. T. Y.

London, July 5th, 1862.

Gossip.

Mr. R. Barclay, of the Montrose Museum, has invented a method of facilitating the inspection of coins, medals, &c., in collections and museums. It consists of a little frame in which the coins are fixed so that by turning it round the obverse and reverse of the coin can in turn be examined, even although protected by glass cases. The invention is very simple, and at the same time might be of great advantage if applied to some of our collections in museums, &c. Mr. Barclay has not patented it, but trusts that those who employ it will send any duplicates, &c., to the Montrose Musuem.

Captain Mansfield, in distributing the prizes among the pupils in the Mercantile Marine Association's School, Ingate, Conway, last week, related the following anecdote :—" To illustrate the importance of knowledge. His grandfather many years ago commanded a line-of-battle ship, and once engaged a French line-of-battle ship of similar size and captured her. (Hear, hear.) He put a prize crew on board, but his own vessel was so riddled that soon after the fight she sunk, and all were lost except himself and fourteen men, who escaped in one of the boats. They had no compass or instrument to steer by except a watch, which told them the position of the sun by day and the stars by night. With the help of that watch alone he steered over 800 miles of ocean and found a port.

M. Lamiral, who has been sent on a scientific mission for the purpose of collecting sponges, in order afterwards to transport them to the coast of Algeria, where endeavours are to be made to acclimatise them, will commence his operations on the coast of Syria. The sponges will have to be taken up together with the fragments of rock to which they are attached; to effect this M. Lamiral is provided with a submarine boat of his own invention. This apparatus is also to be applied to the fishing of the pearl oyster in the Indian waters, and its subsequent introduction into the Mediterranean, as our readers know. Another bivalve will also form the subject of M. Lamiral's experiments—viz., the byssus, which is covered with a thick beard, about eight inches in length. This beard is composed of silky airs, which were woven by the ancient Egyptians into precious stuffs, and then exported to Tyre, where they received the purple dye for which that place was so celebrated. Even now the Sicilians and Calabrese manufacture silky tissues with this substance, which is of a yellowish-brown colour, with a greenish shade.

IMPROVED STEAM FIRE ENGINE.—On Monday an improved land fire engine, by Shand and Mason, was publicly tested in London. The machine can be drawn with as much ease as one of the common hand engines, by two horses. The water was discharged in a steady column above 150 feet perpendicularly. The trial was very successful.

EXPORTS OF MACHINERY.—Ten years ago the value of machinery of all sorts, including steam engines, exported from the United Kingdom, amounted to £1,167,611 only. Last year it reached almost 4½ millions sterling—an increase in the ten years of more than 300 per cent. The countries to which this vast quantity of machinery was sent in 1861 cannot be given, as the accounts for the year are not yet completed, but the particulars for 1860 are subjoined: Russia, £696.264; Sweden, £56,977; Hamburg, £157,204; Holland, £110,956; Belgium, £113,137; France, £171,020; Spain, £308,491; British East Indies, £642,939; Australia, £228,320; Mauritius, £93.239; British West Indies, £111.749; Egypt, £107,527; Turkey, £61,640; Kingdom of Italy, £114,904; Cuba, £84,057; Brazil, £94,315 Prussia, £73,116; Norway, £51,350; United States, £40,218 Hanover, £94,326; all other countries, £426,162; making a total for 1860 of £3,837,821.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgment :—

STEAM ENGINES, &c., 3120, 3123, 3126, 3175.
BOILERS AND THEIR FURNACES, &c., *None*.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 3133, 3149, 3157.
SHIPS AND BOATS, including their fittings, 3129, 3130, 3132, 3182, 3187, 3194.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, *None*.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 3118, 3127, 3139.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 3122, 3131, 3136, 3151, 3153, 3155, 3162, 3165, 3174, 3181, 3183, 3192, 3193.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c. *None*.
LIGHTING, HEATING, AND VENTILATING, 3124.
FURNITURE AND APPAREL, including household utensils time-keepers, jewellery, musical instruments, &c., 3121, 3134, 3145, 3158, 3159, 3160, 3161, 3172, 3176, 3189.
METALS, including apparatus for their manufacture, 3142, 3150, 3186.
CHEMISTRY AND PHOTOGRAPHY, 3147.
ELECTRICAL APPARATUS, 3170.
WARFARE, 3119, 3154, 3166.
LETTER-PRESS PRINTING, &c., *None*.
MISCELLANEOUS, 3125, 3128, 3135, 3137, 3138, 3140, 3141, 3143, 3144, 3146, 3148, 3152, 3163, 3164, 3167, 3168, 3169, 3171, 3175, 3177, 3180, 3184, 3185, 3191.

3186. W. MAKIN. *Improvements in the manufacture of cast-steel, mill chisels, and other taper tools and files* Dated Dec. 20, 1861.

Here the inventor cuts or casts in the face of the forge hammer anvil a recess or die that exactly corresponds with the form of one side of a mill chisel, file, or other taper tool, and he also cuts or casts in the face of the forge hammer a similar recess or die that exactly corresponds with the form of the other side of the mill chisel, file, &c., so that when the hammer is in contact with the anvil, the two recesses or dies together form a mould or groove corresponding with the jointed or tapering end of the mill chisel, file, &c. By this arrangement the steel of which the tool is to be formed on being forged or caused to enter into and fill out the mould or die in the hammer and mill is thus formed into the exact shape required. *Patent abandoned.*

3187. J. and J. STANFIELD. *Improvements in machinery or apparatus for giving motion to ships and machinery, and for raising water.* Dated Dec. 20, 1861.

This consists mainly in the use of an open cylindrical case in which a number of vanes are arranged radially, but which are set in an oblique direction, so that any fluid impinging upon or projected against such vanes shall give a rotary motion thereto, and, consequently, to the case containing them. *Patent abandoned.*

3188. J. SMITH and J. B. HIGGS. *Improvements in thrashing machines, and in mills for grinding, and in raising or moving grain in granaries and other places.* Dated Dec. 20, 1861.

This invention is not described apart from the drawings. *Patent completed.*

3189. C. E. WILSON. *Improvements in collars for gentlemen's, ladies', and children's wear.* Dated Dec. 20, 1861.

This consists in sewing to the collar, at a short distance from its outer edge, a border or hem turned up to the under or wrong side of the collar, and stitched or sewn thereto, and in sewing to the collar on the right side, and near the border or hem, one or other number of tucks, extending parallel with the border from the two extremities of the band. The collars may be cut of any desired shape, either angular or curved at the corners. *Patent abandoned.*

3191. J. WESTWOOD. *An improvement in the construction of hydraulic presses.* Dated Dec. 20, 1861.

The object here is the construction of hydraulic pipes so that the cylinder and ram are capable of being moved to one side or the other of the press by traversing gear fitted to such cylinder. For this purpose the cylinder containing the ram is fitted with a traversing motion, consisting of a wrought iron ring, into which the bottom end of the cylinder is fixed. The ring has straight sides which work in V guides, and on the upper side of the ring are formed two bosses, one on each side of the cylinder, such bosses having internal screws, through which are passed two wrought iron screws mounted in suitable bearings on each side of the lower cross head of the press. These screws have each a spur wheel at one end gearing into a pinion mounted in the centre of the width of the lower cross head, and worked by a winch handle. By this means the cylinder and ram are capable of being moved from one side of the press to the other on the lower cross head, as may be required, but the traversing gear may be varied. *Patent completed.*

3192. G. MAY. *An improved method of utilising bags, wrappers, or other similar articles made of paper or other material, and in any form.* Dated Dec. 20, 1861.

Provisional protection has not been granted for this invention.

3193. G. WALKLAND. *An improved machine for winding lace or other similar fabrics or tissues on cards or other materials.* Dated Dec. 20, 1861.

We cannot here give space to the details of this invention. *Patent completed.*

3194. W. TIPPLE. *Improvements in paddle-wheels for the propulsion of ships and other navigable vessels.* Dated Dec. 20, 1861.

Here the paddles are hung in bearings upon cross-shafts with the dipping paddles or float-boards inclined inwards towards the circle of the travel of the wheel. This inclination is self-existing or adapting, so that the wheel turns upon its axle, and the paddles hang stationary except those that are in action in the water. The angle of inclination is given to the paddle by the leverage that exists in the bearings that are used to hang the paddles. The balancing of the paddle is effected by placing the cross-shaft thereof a little below the centre or middle of the paddle, so that when the paddle is making the sweep under the paddle-shaft the resistance shall be equal, the lesser surface sweeping through the dense or deep water, while the greater surface above the cross-shaft sweeps through the lighter or the shallow water, by which equality of pressure on the surface of the paddle is effected. This being the case it is only necessary to give the paddle stability in its position, which is accomplished by placing compactly shaped weights upon the bottom of the paddles; these weights have a pendulous power, being hung upon the end of a moving leverage. *Patent completed.*

3195. V. D'ALMEIDA. *An improved mode of obtaining colouring matter applicable for dyeing skins, silk, wool, or other fibrous materials.* (A communication.) Dated Dec. 20, 1861.

This consists in extracting colouring matter from a mollusc known by naturalists as the aphysia. The inventor takes several of these animals, and by exerting pressure thereon extracts a liquid colouring matter therefrom, which he places in a vessel, and imparts heat thereto of about 50 degrees of Fahrenheit. To the colouring matter he adds water, varying in quantity according to the tint or depth of colour required, and varying from lead colour to purple. By these mens he obtains colour suitable for dyeing skins, silk, &c , without requiring to use mordants. He also obtains a rich colour resembling that obtained by the use of conchineal, indigo, and carmine. *Patent abandoned.*

3196. W. CLARK. *Improvements in apparatus for the manufacture of matches.* (A communication.) Dated Dec. 20, 1861.

This consists, 1, in obtaining the splints separate one from the other, instead of in the form of a comb, which the inventor effects by the application of a comb or divider placed near the cutting cylinders which separates and conducts the said splints under a reciprocating knife, which cuts them the desired length. 2. In placing the matches or splints in rows in a frame or press, in order to apply the sulphur and phosphorous with rapidity. This frame is placed vertically behind the reciprocating knife, and has a descending motion imparted to it, by which it packs the splints for forming the matches in superposed rows or layers. 3. In the apparatus for transmitting movement to the various parts of the machine. The invention is not described apart from the drawings. *Patent completed.*

3198. R. A. BROOMAN. *A new or improved method of preparing silk fabrics to be employed in the manufacture of hats, caps, and bonnets.* (A communication.) Dated Dec. 20. 1861.

The object of this invention is the preparation of silk fabrics to fit them for the bodies of hats, caps, and bonnets, without the employment of any other stuff. The invention consists in applying to the back of the silk fabric various dressings which render it waterproof, and impart to it the necessary stiffness for the bodies of hats, caps, and bonnets. The preparation of the silk is effected by successive dressings, and those which are preferred are as follows :—The inventor begins by spreading over the back of the silk a layer or coating of gelatine, and allows it to dry. He then applies a coating of caoutchouc, and over this the dressing usually applied in the trade. The silk will thus have acquired the necessary stiffness and impermeability without the face being touched, and which consequently preserves all its lustre and brilliancy. *Patent abandoned.*

3199. E. E. PEREAU. *An improved composition for cleaning and revivifying woollen cloths and other fabrics and the colours thereof.* (A communication.) Dated Dec. 20, 1861.

This composition is made either white or coloured, and in either case the patentee gives it the trade name of "Eau ecarlate." It cleans and removes the stain from, and revivifies the colour of, woollen and other fabrics, as well as the fabrics themselves. It is formed of citric acid, carbonate of potash, alum, alcohol and water, to which colouring matter, say, for instance, cochineal, may be added to impart the colour required. *Patent completed.*

3200. R. WAILES. *An improved tool or apparatus for cleaning windows and glass.* Dated Dec. 20, 1861.

This apparatus is intended chiefly for cleaning the outside of windows from the inside, but it is also applicable for cleaning windows and glasses generally. The improved tool or apparatus consists of a plate of any convenient size, say eight inches by five, clothed on the face with felt, woollen or other cloth, and padded or not with wool or other soft material between the face of the plate and the cloth; the cloth is again covered with silk. To the back of the plate a holder is hinged. To admit of the holder being held at any required angle with respect to the plate, the patentee also adds a rack or other means whereby the said angle may be adjusted, and the respective positions fixed according to requirement. The lower end of the holder is inserted in a handle. *Patent completed.*

3201. T. and W. GREEN, and R. MATTHEWS. *Improvements in lawn-mowing rolling collecting machines.* Dated Dec. 20, 1861.

Here, in constructing lawn mowers, the patentees make the outer edges of the main drum or drums rounded, so as to prevent them cutting or marking the turf. When two

drums are employed, they place the catches for throwing the cutters into or out of work between the two drums, and arrange them so that they are both acted upon by one lever instead of two as hitherto outside of each drum. To adjust the cutters (usually spiral blades ranged round an axis) they employ carriages or plummer blocks having a set screw acting on the top, and a spiral or other spring on the under side of them, the carriages or plummer blocks carrying the axis of the cutters; this arrangement allows of the adjustment to the greatest nicety. To give motion from the drum shaft to the spiral cutters, they employ an internal toothed wheel on the drum shaft, by which they can employ a wheel of greater diameter than when using an externally toothed wheel. The grass boxes of mowing machines they make of thin sheet iron, having suitable devices stamped upon them ensuring strength and lightness. The front or leading roller is made of thin iron discs having bosses on each to keep them any suitable distance apart, the discs being mounted on an axis, and each disc being free to revolve. *Patent completed.*

3202. G. T. BOUSFIELD. *Improvements in machinery for attaching the soles of boots and shoes to the upper leathers.* (A communication.) Dated Dec. 20, 1861.

This consists in a machine which, when placed upon the edge of the sole after it is temporarily secured to the last upon which the upper leather is stretched, will, on being struck by the blow of the hammer of the operator, make a hole for the reception of a peg, drive a peg through the sole and upper leather, move itself along so as to be in position for a repetition of the operation, and feed up the peg wood so as to bring another peg into the proper position to be split off and driven. The invention is not described in detail apart from the drawings. *Patent completed.*

3203. D. C. LE SOUEF. *An improvement of cylinders used in printing calicoes and other textile fabrics.* (A communication.) Dated Dec. 20, 1861.

This consists in coating or covering cast-iron cylinders with copper, by any of the processes of electro-plating iron with copper. The copper surface thus produced on the iron cylinder or roller is then engraved with the desired pattern or design, and used in place of the solid copper rollers. *Patent completed.*

3204. J. WAKEFIELD. *Improvements in sewing machines.* Dated Dec. 20, 1861.

The object here is an improved mode of regulating the movements in relation to the shuttle, so as to obtain an increased facility in adjusting movements to the action of the shuttle. For this purpose, the crank-pin on the driving shaft is made to work in a slot in an oscillating-rod connected by a link, with the ordinary rocking shaft, which acts on the needle bar. The slot in the said rod is so formed as to impart to the needle-bar, through the above connections, a slow motion, when the needle is passing through the material to be sewn, next to raise the needle bar so as to make a loop in the thread, then to allow the needle-bar to rest while the shuttle is passing through the loop as required to form the stitch, and then raising the needle to take up the stitch. The rod has also a straight slot at the lower part, so as to admit of its moving up and down as required, through which slot is passed an adjustable pivot for the rod to oscillate thereon. This pivot carrying a roller is adjustable by a screw passed through a slot in the frame of the machine, so as to give greater facility for accurately turning the movements of the needle in relation to the shuttle. *Patent abandoned.*

3205. T. MORRIS, R. WEARE, and E. H. C. MONCKTON. *Improvements in submarine and other telegraph communication, and in apparatus connected therewith.* Dated Dec. 21, 1861.

Here the electric current employed is obtained by the medium of an induction coil of the following construction. Upon an iron core, or a bundle of iron wires, two or more layers of thick insulated copper ribbon are to be coiled; one end of this wire or ribbon is attached to one side of a voltaic battery, and the other to one side of an automaton break of a novel construction, and the other side of this break is attached to the other side of the battery. This automaton break is self-cleaning, whereby a more uniform action is obtained. Instead of causing a spring to come in contact with a pin, the patentees make the break spring in two parts, or divide it so that the break pin passes between the slit of the spring, or between the two springs, by which means the friction keeps the surface clean, thereby making better contact between the battery and primary wire or ribbon. To this break is attached what is termed a condenser, which is constructed as follows:—Sheets of gutta-percha, india-rubber, &c., are cut to the desired size, and upon each sheet is laid a sheet of metallic foil, cut a little smaller than the sheets of insulating material, and placed alternately to extend over the insulator at one end, for the purpose of being connected in such a way that, if the condensers consisted of thirty plates or sheets, twenty-five of them would be connected at each end, these ends being joined to the break Upon the thick wire or ribbon, and carefully insulated therefrom, they coil a finer insulated copper wire, and between each layer they insert a sheet of gutta-percha, india-rubber, or varnished paper, and as they increase the number of layers, they increase the thickness of the insulating material. The first end of this thin wire may be connected with a line wire of a telegraph, or to the earth connection, the last end of the coil to one side of an instrument, which they term an interrupter, and the other side of the interrupter is to be joined to the telegraph. The interrupter they construct in the following way:—Upon an insulated stand they erect two metal pillars, having connecting-screws to attach the wire from the coil, and the wire from the telegraph. Upon these pillars they arrange an adjusting screw or screws, by which the conducting wire is divided, and may be adjusted to any amount of separation according to the length of the communicating wire. *Patent completed.*

3206. W. BENNETTS. *Improvements in the mechanism required for and in the manufacture and composition of gunpowder.* Dated Dec. 21, 1861.

The ingredients employed are lime, nitre, sulphur, and charcoal; the lime is dissolved in sufficient water to bring the other ingredients into a paste. The lime, after having been made into a solution, is strained through a fine sieve. This solution is then added to the other ingredients, and the whole is ground until it becomes a paste; it is next passed between two rollers, one of which is grooved, and the other plain. The paste, by passing through the rollers, is formed into long strips of a triangular shape. It is next carried on an endless web or canvas over some hot tubes, and it is now in a state in which it can be easily broken into grains. *Patent completed.*

3207. F. GRIMALDI. *Improvements in rotary steam-boilers.* Dated Dec. 21, 1861.

This relates to the invention for "the instantaneous generation of steam," for which a patent was granted to the present patentee, 9th August, 1860 (No. 1,927). The most important part consists in fitting the rotatory boiler either with small tubes or internal flues, so as to greatly increase the heating surface. In case of the boiler being fitted with tubes, the latter almost fill the boiler, leaving only some space for the steam and feeding pipes. When the boiler is a flue one, the internal flues are generally four in number, and are placed round the axis of the boiler. The invention also consists of taking the steam as near as possible to the top of the boiler, so as to prevent any priming. Therefore, the steam-pipe on entering the boiler through one of the tubular trunnions, is bent up to the top of the boiler, as far as it can go. This arrangement, however, is not applicable to those boilers which are fitted with straight tubes or straight flues. *Patent completed.*

3208. W. M. WILLIAMS. *An improvement or improvements in treating coal and other bituminous minerals, and peat, in order to obtain solid and liquid hydrocarbon therefrom, and in apparatus to be used for that purpose.* Dated Dec. 21, 1861.

The patentee claims, 1, treating coal and other bituminous minerals and peat, so as to obtain solid and liquid hydrocarbons therefrom, that is to say, subjecting these substances to a distillatory process, so conducted that the volatile products produced pass rapidly downwards from the heated part of the apparatus, so as not again to be exposed to a temperature equal to that at which they were produced. 2. Constructing and arranging the retorts or distillatory vessels so that heat is applied at the top of the said vessels, and the volatile products conducted by a descending motion from the heated parts of the said apparatus. The invention cannot be fully described apart from the drawings. *Patent completed.*

3209. A. L. ALLCHIN, and W. ALLCHIN. *Improvements in apparatus applicable to the superheating of steam.* Dated Dec. 21, 1861.

Here, for locomotive or portable boilers, the patentees construct a series of tubes in a syphon, or approximatively syphon form, placed within the smoke box and above the flue tubes of steam-boilers. This apparatus is to be connected to the steam space of the boiler, and also to a pipe through which the superheated steam is conveyed to the cylinders of the steam engine. They also construct a double channel or box of a D form, with an outer and an inner coating, leaving sufficient space for the steam between, and thus secure the action of the heated gases in the smoke box of a boiler, and this box or chamber is connected to the steam space of the boiler and to the cylinders of the engine. In constructing stationary boilers they connect a series of tubes of convenient length in a syphon, or approximatively syphon form, placed within the flues or tubes of a boiler. They also connect one or more ends of these tubes to the steam space of boiler, and to a pipe or pipes conveying the superheated steam to the cylinders of the engine. They also construct a tube or tubes one within the other. The heated gases pass through the inner tube, and around the external portion of the outer tube or tubes, the space between being occupied by the steam to be superheated. They connect these tubes or pipes together at each alternate end or otherwise; or they may be all connected together at one end to a pipe or pipes from the steam space of a boiler, the other end or ends being connected to the steam pipe or pipes, so as to convey the superheated steam to the cylinders of the engine. For marine engines, it will only be necessary to modify the details of the above arrangements according to the form of the boiler. *Patent completed.*

3210. W. C. MILES. *Improvements in lamp-glasses.* Dated Dec. 21, 1861.

Here the inventor uses a glass globe and also a glass chimney, but instead of the chimney descending within the globe, it terminates at the top of the globe, on which it may be fitted to remove as desired. *Patent abandoned.*

3211. F. SELBY. *Improvements in boilers for the generation of steam in engines for applying motive-power purposes, and in wheels and ways for steam carriages to run on.* Dated Dec. 21, 1861.

The first part of these improvements relates to the construction of the boiler or generator, by which steam is very rapidly made. The patentee calls the boiler "a multitubular coil" boiler. The coils are of small diameter and fixed vertically, and take the place of ordinary straight boiler tubes when vertically fixed. The shell of the boiler may be of any convenient form, and may be double cased to form water spaces. The water passes through the coil tubes and the fire acts outside around them. Further, for a circular or other vertical boiler, the steam is collected in a dome, a separate part from the boiler, through which the gases from the furnace pass, by means of a number of vertical tubes placed in the dome, into the stack, whereby the steam becomes superheated. The second part of the invention relates to the cylinders when used of different diameters with expansion and with or without condensation. He places the small cylinder into which the steam first enters within a larger cylinder, which larger cylinder is therefore an annular cylinder, and these two are placed (if desired) in a still larger cylinder, which would also be an annular cylinder. The valves can be arranged as desired, either with a single valve rod and single eccentric, or with separate rods and eccentrics; also the cranks may be opposite or in the same line, and one crank may be used as found most convenient, or the cranks may be at right angles. The third part of the invention relates to the transmission of motion from the crank axle to the driving axle, where gearing is used, specially applicable to paddle-wheel steamers, traction and locomotive engines. The driving axle being much subject to vibration is made into two shafts, that is, is divided in the centre; the inner ends are hung on swivel or ball bearings, whereby the shaft is allowed to move in one direction both up and down; the geared wheels hang over the centre of these bearings, and being geared into a pinion or wheel on the crank axle can never get out of gear, or cross the teeth, one fitting into the other, the face of the wheels being convex and concave according to the radius taken from the swivel bearings and the diameter of the wheels. The other ends of these half shafts are fixed as is usual, and kept in their places by springs. The fourth part of the invention relates to the wheels of locomotive and traction engines, and the tram-way for them to run on. The rim of the wheel is made of an inverted V shape, with or without flat side rims, so as to run on a tramway or not; the rails are in the form of tubes of wrought or cast iron, or of a half circle, by which means the engine will gain more tractive power than with ordinary flat rails. Where no tramways are used, he fixes a flange on both or either side of the wheel, which may be called a flange wheel, of smaller diameter than the other part of the rim, so that when the engine runs over soft ground, it will bear on the flanges as well as on the wheels; and lastly, he fixes on the rim of the wheel, at convenient distances apart, plates, by preference, in the form of horse shoes, to give greater power to the forward motion of the engine, and thereby prevent slipping. *Patent completed.*

3212. W. KEMPE. *Improvements in scrays or tables applicable to gig mills, brushing mills, and other like machinery.* Dated Dec. 21, 1861.

The patentee claims the construction of mechanism as described, whereby the folds of cloth received on to a moveable scray are caused, by the form and motion of the scray, to be turned over before passing off the scray, and so that that which was undermost when received on to the scray is uppermost when about to pass off the scray. *Patent completed.*

3213. C. OSMAN. *Improvements in the manufacture and application of elastic or yielding surfaces for sitting, lying, or reclining upon.* Dated Dec. 21, 1861.

This consists, 1, in manufacturing elastic surfaces of vulcanized india-rubber of cellular form, and in applying the same to the construction of cushions, mattresses, chair and couch seats, &c. 2. In forming elastic or yielding surfaces for sitting, lying, or reclining upon, by connecting the upper or lower ends, or both, of a series of lever arms by strips or bands of vulcanized india-rubber. 3. In forming elastic or yielding surfaces by a series of curved springs, arranged and supported on a fixed stationary surface or surfaces, such springs being caused to support a cushion, mattress, or other surface for sitting, lying, &c., so as to yield on pressure being applied to any part. 4. In forming elastic surfaces for sitting, lying, &c., by causing the cushion, mattress, or seat to be supported upon projections carried by a series of helical or other springs. *Patent abandoned.*

3214. J. H. JOHNSON. *Improvements in apparatus for cleaning wheat and other grain.* (A communication.) Dated Dec. 24, 1861.

This apparatus consists of a vertical shaft, provided with a number of dished or inverted truncated cones, having their peripheries higher than their centres. Between each pair of these plates is a stationary, conical, or dished-shaped plate, similar to those carried by the vertical shaft, but secured to an outer casing which surrounds this portion of the apparatus. Inside the outer casing, which is provided with openings at intervals, is fitted a perforated or roughened metal plate or cylinder, against which the grain which falls on to the upper one of the set of revolving plates is directed or thrown by the centrifugal force generated by their rotation, and then falls on to the stationary plate beneath, which directs it to the centre of the next lower revolving plate, when it is again thrown against the perforated roughened plate, and falls on to the next stationary conical plate, and so on, finally entering a coffer, and passing down a shoot to a riddle or sieve, being surrounded by a fan blast as it is leaving the mouth of the shoot. The degree of inclination of the rotatory and fixed plates will depend upon the speed at which the apparatus is to be worked. *Patent completed.*

3215. L. R. BODMER. *Improvements in looms for the manufacture of sacks, knapsacks, mattress cases, and other goods.* (A communication.) Dated Dec. 24, 1861.

This invention is not described apart from the drawings. *Patent completed.*

3216. MRS. C. SMITH. *Improvements in stays.* Dated Dec. 24, 1861.

This invention relates to stays for adults and children, and consists in applying to the back of stays means for adjusting the stays to the body of the wearer after they have been fastened in front, that is to say, means of tightening the stays, or allowing them to expand so as to cause them to fit more perfectly or comfortable. Near the centre of the back of the stay the patentee makes a vertical opening strengthened at each edge by bones or other stiffenings, which she prefers should extend from the top to the bottom of the stay, and from the bottom of the stay to, say about four inches upwards, more or less, she inserts a gore, which may be of the same material as that of which the stay is made, between the two bones or stiffenings. The upper portion of the parts so strengthened by bones or otherwise she connects together by means of a piece of material which may be of the same description as the rest of the stay, so that there shall be a slot or opening of a length equal to about one-third the height of the stay. To each edge of the opening she fixes a strap of any suitable material, which is made sufficiently long to extend to the front of the stays, or nearly so. She attaches the straps to the stays in such a way that one of the straps shall pass under the other, and the end of each strap is

made capable of being secured in front to fastenings fixed to the stays, in such a manner that they may be drawn more or less tight at pleasure, and there fixed, so as to cause the sides of the opening at the back to be drawn and held more or less nearly together. *Patent completed.*

3217. J. ROBINDELL. *An improved method of, and apparatus for, separating solid from liquid substances.* Dated Dec. 24, 1861.

This invention consists in effecting the separation by means of metal strainers or bags of some pervious material, placed in metal or other frames under and in communication with a pipe or pipes, in which a pressure of the liquid from which the solid is to be separated is maintained by a head or column of the said liquid. The liquid itself is held in a supply tank at the top of the column, and cocks are fitted at top and bottom of the pipes to admit and shut off the supply as required. *Patent completed.*

3218. MRS. C. SMITH. *Improvements in stays.* Dated Dec. 24, 1861.

This invention relates to stays for adults and children, and consists in the employment of fastenings permanently attached to each side of the opening in the front of stays, so as to avoid fixing any fastenings upon the steel or other busks of the stays, which are made plain, and removeable as hereinafter described. One part of each of the fastenings is fixed to one side of the opening of the stay, and the other part of the fastening to the opposite side of the opening, so that when the stay is put upon the body with the opening in front of the wearer, the corresponding parts of the fastenings may be put together so as to secure the sides of the opening. The busks which the patentee prefers to use consist of a plain strip of steel rounded at top and bottom. For every pair of stays two such busks are used, one being inserted in a sheath made for its reception at each side of the opening. When the stay is on the wearer, and fastened, the two busks are brought near together, and give the necessary and usual support in front. *Patent completed.*

3219. E. EDE. *Improvements in the construction of horse-shoes.* Dated Dec. 24, 1861.

The iron used for the purpose of this invention consists of a flat bar, having a ridge along the centre of the upper side thereof, such ridge being of any desired height. The flat portion of the iron is placed next the horse's foot. *Patent abandoned.*

3220. J. F. HARVEY. *Improvements in umbrellas and parasols.* Dated Dec. 24, 1861.

Here the patentee forms the top notch upon a tube extending downwards to carry the top catch, so as to avoid the necessity for applying the top catch in the stick, as is the general practice, and by which the stick is weakened at that part. He also forms this tube, by preference, of an internal diameter, larger than that of the same part of the stick, by which the improvements are well adapted to those sticks which are of a taper form. The tube of the top notch may be packed to the stick, and it may be held to it by riveting, and by the gathering in of the lower edges or other part. The runner is formed with its tube extending upwards, and so as to pass closely on to the tube of the top notch, with a slot or slots to receive the top catch. This tube of the runner also carries a ring or slide to act upon and release the top catch when the umbrella or parasol is desired to be closed. He also applies a cap acted on by a spring, by which it has a tendency to slide over, and by enclosing the ends of the stretchers, to hold the parts close, and retain the parasol or umbrella closed. *Patent completed.*

3221. A. V. NEWTON. *Improved means for reducing the friction and wear of slide valves for steam-engines.* (A communication.) Dated Dec. 24, 1861.

This consists in combining the slide-valve of a steam-engine with a well-known arrangement of mechanism termed the "parallel motion," from which it results that the valve is sustained by such mechanism, so as to prevent it from being pressed to its seat with a force due to the pressure of the steam, while at the same time it permits the valve to slide back and forth on the required plane, thus greatly reducing the friction and the wear of the surfaces of the valve and valve-seat. The invention also consists in combining with the slide-valve and the "parallel motion" a spring, or the equivalent therefor, which will yield to the pressure of the steam on the valve, and thereby ensure the contact of the face of the valve with its seat. The invention also consists in combining with the frame in which the "parallel motion" mechanism is mounted (and which is contained in the steam chest) a lifting mechanism, extending to the outside of the steam chest, by which the valve can be lifted entirely clear of its seat, to prevent the wear of the parts during the working of the engine after the steam has been shut off. *Patent completed.*

3222. T. E. VICKERS. *Improvements in the wheels of railway engines and carriages, and in the machinery or apparatus to be used in making the same.* Dated Dec. 24, 1861.

This consists in casting the wheels in steel, and of a disc form, of a peculiar character. The nave and rim, or tyre, of the wheel, together with the disc which connects these parts together in the place of spokes, are all cast in one piece, so that there will be no danger of the rim or tyre becoming loose, or coming off. Also in constructing these disc wheels with double corrugations, so combined as to cross each other This form of disc wheel is cast in a mould lined with fire-proof material, as described in the specification of a patent granted to E. Riepe, on the 9th July, 1853 (No. 1637). The mould may be made from a wooden pattern, or by means of an apparatus which forms the subject of a part of this invention. *Patent completed.*

3223. E. B. SIMPSON. *Improvements in apparatus for drying wool and other fibres and substances.* Dated Dec. 24, 1861.

For the purposes of this invention a rotating vessel or chamber, of a cylindrical form, is employed. The vessel has two ends or covers, through which the axis of an internal heating chamber or vessel pass. The ends or covers are formed with holes or openings to allow steam or vapour from the wool or other substance (such as feathers and seeds) within the vessel to pass away freely; it is preferred that holes or passages should be formed for the same purpose in the revolving chamber. It is desirable that after provision has been made for the free passage away of steam or vapour, the rotating vessel should be as close as may be, to retain the heat therein. In order to introduce and remove the substances into and from the revolving vessel, part of the periphery is made to open. Within the revolving vessel there are rows of projecting teeth, radiating towards the centre, or other provision is made in order that the wool or other substances may not slip towards the lowest part of the vessel as it revolves on its horizontal axis. The internal central vessel is likewise cylindrical, and heated with steam. The mode of applying heat may be varied. It is desirable that this internal vessel should revolve so as to ensure that the wool or other substance when it falls on to the heating vessel, shall slide therefrom on to the lower part of the rotating vessel or chamber. If desired, the rotating vessel may be made of such a form as to admit of its being heated, and thus by its heat also contribute to the drying of the substance. By these arrangements the wool or other fibre within the vessel will be continually raised up to the highest position, and then allowed to descend to the lowest position, through the heated atmosphere of the chamber, and in contact with the heated surface. *Patent completed.*

3224. J. B. WOOD. *Improvements in the manufacture of driving straps or bands, the backs of wire cards, and cop tubes.* Dated Dec. 24, 1861.

In the manufacture of driving straps or bands, the inventor takes buffalo hide, previously macerated in water, and converts the same into pulp by rollers or otherwise. The mass alone, or mixed with flax, &c., is passed through rollers, some of which are covered with felt, then passed over warm cylinders, and finally cut into the proper widths for straps or bands. In the manufacture of cop tubes the substance or pulp is rolled out into thin bands, the width of which is in accordance with the length of the tube required, and, when partially dry, is cut into lengths of the shape and form required, each length being subsequently wound upon a steel mandrel; it is then placed in a die adapted for the purpose, the pressure of which converts the folds of the tube into one uniform substance. *Patent completed.*

3225. F. LAURENT and J. CASTHELAZ. *Improvements in the manufacture of colouring matters.* Dated Dec. 24, 1861.

Here the patentees take nitro-benzine, or nitro-toluine, or other homologue of nitro-benzine, or a mixture of these substances, or a substance containing some or one of them, and by a process of deoxidation they obtain a red colour, varying somewhat in shade, ascending to the method in which the deoxidizing process is conducted, and the extent to which it is carried. The decarbonizing process preferred is to mix with the nitro-benzine or other material, iron-filings and hydro-chloric acid. The colouring matter when formed may be purified by dissolving it in water, and precipitating it by saline solutions. *Patent completed.*

3226. J. COCHRANE. *Improvements in apparatus employed in sinking cylinders and open coffers for forming foundations under water.* Dated Dec. 24, 1861.

Here, when sinking cylinders or open coffers of other sections, there is formed at the upper part a chamber with an opening into it from the outer atmosphere, and also an opening into the cylinder or coffer below. Both these openings are arranged, as heretofore, to be closed air tight, and are for the passage of the workmen into and out of the cylinder or coffer; the required length of cylinder or coffer of other section is also, as heretofore, made in suitable lengths, provided with internal flanges to fix them together. The buckets to carry up the earth or materials are caused to ascend and descend in a pipe or pipes, which descend from a point above the upper closed chamber down to, and so as to dip into, a recess or well, if desired, where the work is being carried on. The descending pipe is made in lengths, corresponding with the lengths of the cylinder or coffer of other section, and is of such diameter as to allow a bucket to pass up and down freely, leaving a space all round for the free passage of water. By these means when the water is driven out of the cylinder or coffer of other section by compressed air, it will remain in the pipe, and will stand at or about the same level as it does outside of the cylinder or coffer. The buckets are raised and lowered by any suitable mechanism outside of the cylinder or coffer, and, consequently, the only workmen who will be working in a compressed atmosphere will be those who are digging or removing the earth or materials at the bottom of the coffer, and they will, when they have filled a bucket, place it under the lower end of the pipe, and attach it to a chain or rope, when the full bucket will be raised up through the water in the pipe. *Patent completed.*

3227. G. H. BIRKBECK. *Improvements in the arrangement of traction and connecting apparatus for railway carriages and trains.* (A communication.) Dated Dec. 24, 1861.

This invention is not described apart from the drawings. *Patent completed.*

3228. T. SIMMONS. *Certain improvements in urns or vessels for holding and supplying hot water, tea, coffee, or other liquids, separately or conjointly, as also in the stands for the same.* Dated Dec. 26, 1861.

This consists in so dividing the interior of the urn that tea, coffee, &c., may be held in separate compartments, the taps, &c., being arranged for drawing off and supplying the various contents. The patentee proposes supplying heat from a light suitably placed below the body of the urn, the light of which is appropriated for the illumination of transparent pictorial designs suitably placed around the base or stand. *Patent completed.*

3229. J. JONES. *Improvements in the manufacture of lead, tin, and other metals of a like nature, fusible at a low temperature, into sheets of any thickness or length.* Dated Dec. 26, 1861.

This apparatus consists of a cylinder of iron, heated by surrounding the external vertical side thereof with a fir or otherwise. This cylinder contains the molten metal, and is placed immediately above a hydraulic press, the head of the ram of which forms a piston, working within the cylinder, which is used to force out the metal through a die or dies fitted on to the top of the cylinder. These dies may be kept cool by a current or currents of water passing through internal passages in them. The sheets of metal as ejected are received on rollers, and are immediately ready for use. The metal for supplying the cylinder is melted in a vessel placed above the cylinder, and communicates therewith by a pipe. *Patent completed.*

3230. T. STANDING. *Improvements in cinder-sifters and ash receptacles, applicable to domestic fire-grates.* Dated Dec. 26, 1861.

Here the patentee places beneath an ordinary stove a combined cinder-sifter and ash receptacle, the sifter being composed of woven wire work, or perforated metal plate, and supported on a frame which can slide to and fro on fixed rods extending across the ash-box, at a slight elevation from the bottom thereof. A knob or handle in front of the grate or stove, and connected by a short rod with the supporting frame of the sifter, serves to impart a to and fro shaking or vibratory motion to the sifter when requisite, whereby the ashes are collected in the ash-box beneath. *Patent completed.*

3231. L. J. TAULIN. *A wind musical instrument, "Taulin's harmonicor."* Dated Dec. 26, 1861.

This consists in the construction of a portable wind instrument, with free reed stops, with which all kinds of music may be performed. This instrument the inventor prefers to make of metal. The notes are formed by pistons, and from the chromatic gamut the number of notes on the instrument can be greater or less as desired. The mouth-piece is in the form of a small beak; there are two hooks in which the left hand is placed to hold the instrument, so that the right hand can move the pistons to sound the notes desired. The notes emitted at the same time by the instrument can be retained in any number in order to produce chords. *Patent abandoned.*

3232. J. SCHLOSS. *Improvements in envelopes for containing photographic pictures and portraits.* (A communication.) Dated Dec. 26, 1861.

This invention consists in forming envelopes intended chiefly for containing "carte de visite" portraits and for their being forwarded conveniently by post, as hereafter described. The inventor takes a sheet of paper or paper cloth or other material suitable for envelopes, and of a breadth equal to the length of the envelope when finished. He forms the usual flap at one end of the paper, and forms a frame in or on the opposite end, either by folding the paper over on itself, or by the employment of a separate frame of paper. In the first case, that is where the paper is folded over, he first cuts the "window" or aperture therein for showing the picture, and cements the top and bottom edges to the other part of the sheet; one side will thus remain unattached for the insertion of the picture. Where the frame is in a detached piece, he attaches it at top and bottom and one side. After insertion of the picture, that part of the sheet on which the frame is applied, together with the picture and frame, is folded over, and the flap is folded over the back of that part on which the frame is applied. When several pictures are to be enclosed, he uses a greater length of paper, and applies additional frames, and where only two pictures are to be enclosed, he applies an additional frame on that part of the paper which, when the envelope is folded, covers the face of the first picture. *Patent abandoned.*

3233. N. A. BURNIER. *Improvements in the manufacture of lace.* Dated Dec. 26, 1861.

The lace produced by the invention is dedominated by the inventor Bandanah lace. It is manufactured upon ordinary lace looms, the peculiarity of it being that it is almost entirely composed of spun silk of such a description as will best receive colours, the brightness of which almost assimilates this material to ordinary silk. *Patent abandoned.*

3234. J. SHEPHERD. *Improvements in apparatus for cleansing steam boilers.* Dated Dec. 26, 1861.

In order to collect, carry off, and discharge the sludge, sediment, and scum contained and formed upon the surface of the water in steam boilers, particularly during ebullition, the patentee employs one or more floating receivers made buoyant by air-tight chambers, balance weights or other suitable means to render them moveable. These receivers are adjusted to any given distance below the surface of the water, and are connected to the water pipe or pipes by tubes within each other, similar to a telescope, or by jointing one tube so that it can work in and over another tube, in order that the receivers may rise or fall with the surface of the water, the collected refuse being discharged from the receivers and waste pipe or pipes by taps, valves, or other suitable means. In order to expel from the boiler such sludge, sediment, or other matter that may fall to the bottom part of the shell or framework of the boiler, he employs one or more vertical or other shaped pipe or pipes fitted with a nose, perforated disc, or conical mouth piece; these pipes are under sludge extractors are connected to the main waste pipe. The whole area of the openings into the said main pipe is to equal, but not to exceed the area of the said main or chief waste pipe. *Patent completed.*

3235. R. NEEDHAM. *Improvements in apparatus for cleansing steam boilers and lubricating the pistons of steam-engines, and for an improved steam trap.* Dated Dec. 26, 1861.

For cleansing steam boilers, the patentee places in the exterior of a boiler a pipe extending longitudinally from end to end, and connected at one end to a vertical pipe communicating with a cock or valve on the outside. The said pipe is placed at the bottom of the interior of the boiler, or at some distance above it, and has connected to its top a number of vertical pipes, each opening in the shape of a funnel at the level of the water. The said funnels face the front or firing end of the boiler, so that the scum shall, of necessity, enter them in consequence

of the heat at the front end of the boiler, causing the flow of water towards the back. The scum, after entering the funnels, passes through the longitudinal and vertical pipes to the cock or valve on the outside, which is opened, when required, to let off the scum. *Patent completed.*

3236. H. DAWES. *An improved metal for crinolines.* Dated Dec. 26, 1861.

This consists in subjecting the steel to a process of electro-typing with an inferior metal, such as zinc, copper, tin, brass, by which the steel will withstand rust or corrosion from the atmosphere, and will maintain a bright and smooth surface. *Patent abandoned.*

3237. J. N. PALMER. *Improvements in cooking stoves and ships' ranges.* (A communication.) Dated Dec. 26, 1861.

This consists in the introduction of a flue at the back of the stone with the view of increasing the draught, and allowing the heat to pass all round the ovens and up the chimney or pipe, thereby heating the bottom of the ovens as well as the top. Also in supporting the stove pipe by means of a separate cast-iron oblong pipe attached to the back of the stove, to allow the top or hot plate to be removed for the purpose of cleaning out the flues without taking down the pipe. Also in the introduction of a cast-iron perforated fire-back or shield in the fire-pot, with the view of allowing the air to pass up from behind, increasing the draught, protecting the fire-pot, and permitting the fire-back to be replaced when burnt out without removing the fire-pot. *Patent completed.*

3238. W. HAWKSWORTH. *Certain improvements in carding engines.* Dated Dec. 27, 1861.

This consists of apparatus for stripping the fleece off the doffer of a carding engine. The stripping comb is made of several pieces screwed or otherwise fixed to a back or stock, made of hollow sheet metal of a semi-circular shape, in order to combine strength with lightness. The comb and stock are guided up and down by rods working in fixed bearings, and they are put in motion by a crank, eccentric, or cam, the side links from which are connected to the trunnions on which the comb swivels, so that the teeth of the comb in the down stroke are sufficiently near the doffer to strip off the fleece; but in the up-stroke they are moved slightly from the doffer, and thus clear the wires. *Patent completed.*

3239. T. SILVER. *Improvements in apparatus for governing or regulating the speed of steam and other engines.* Dated Dec. 27, 1861.

This consists in taking advantage of pneumatic resistance, to the motion of mechanical apparatus of various forms and arrangements, in which the reacting force or power may either be a spring or suspended weight, and also the accumulation of pneumatic force as a power operating against a re-acting spring or counter-weight. The first arrangement refers to rotary apparatus or instruments, and the second to the accumulation of force within closed vessels. *Patent completed.*

3240. W. TURNER and T. W. GIBSON. *Improvements in rolling bridges.* Dated Dec. 27, 1861.

Here the patentees construct the platform or roadway by combining two or more trussed girders, by preference of wrought-iron, or of wrought and cast-iron combined, although they may be constructed of wood and iron-plated. The underside of the girders form longitudinal rails which run upon bearing rollers, erected upon a centre pier or quay-wall, about the middle of the length of the bridge, or on the tail pit-side of the opening spanned by the bridge. They mount the bearing-wheels, whether there be two, three, or more of them in the width of the bridge, on a pier or other suitable foundation, in such position as to be about the centre of the length of the bridge, or rather nearer to the overhanging or forward end of the platform, and by longitudinal bearing rails of suitable section, fixed to the under side of the platform, at such an angle or inclination as shall best suit the particular application or the dimensions of the bridge. These rails support the overhanging end of the bridge, whilst a back (or there may be more than one) is fixed parallel with the bearing rails, and at the same angle or inclination. For the purpose of opening and closing the bridge, or moving the platform backward and forward, a pinion mounted upon a horizontal shaft is made to take into the rack, and motion is communicated to the horizontal pinion shaft by any of the ordinary wheel gearing or arrangements used for such purpose, so that the bridge may be opened from any convenient part. *Patent completed.*

3241. P. A. LE COMTE DE FONTAINE MOREAU. *Improvements in treating fatty and resinous bodies, either in a neutral or acid state.* (A communication.) Dated Dec. 27, 1861.

This consists in the treatment of fatty and resinous bodies with intramidine, a substance composed of a mixture of potash, flour, and nitric acid, in preference to any other compound capable of forming nitrous vapours or gases, it having the property of hardening fatty bodies without colouring them too much, and of disinfecting them, and especially of favouring more than any other agent the production of elastic acid. *Patent completed.*

3242. T. BRIGHT. *Improvements in machinery for cutting hay, straw, and other vegetable substances.* Dated Dec. 27, 1861.

This consists, 1, in supporting the top, or rising part of the mouth piece of chaff-cutting machines, and other machines of the like nature, with radius bars which guide it in its upward and downward motion, and which also form the bearing for the axis of the top feed roller. The object of this part of the invention is to form an expanding mouth piece to keep a uniform pressure on the hay, straw, or other vegetable substances to be cut according to the depth of the feed. The invention consists, 2, in passing a spindle across the mouth piece of the machine on which is placed a small toothed pinion, that works into an internal toothed wheel fixed on the axis of the bottom feed roller, by which means the spindle and bottom roller are made to revolve towards the mouth; on the cross spindle the other end is a toothed pinion working into a toothed wheel to give motion to the top feed roller, the ross spindle being worked in the usual way with a spur wheel. It consists also in making the bottom of the feed trough for chaff-cutting machines, &c., of an endless haircloth, or other suitable material, to revolve on two rollers fixed in the feed troughs to take the hay, straw, or other vegetable substances to be cut into the feed rollers of the machine. Motion is given to the haircloth, or other suitable material, by fixing a pulley on the axis of the front roller in the feed trough, the pulley being worked by a strap passing over it, and over the ring of the internal toothed wheel on the axis of the bolt roller. *Patent completed.*

3243. T. W. ATLEE. *Certain improvements in cocks or taps, for drawing off fluids.* Dated Dec. 27, 1861.

This consists in forming cocks or taps for drawing off fluids, with a spiral groove or thread, or grooves and threads, around the shank of such taps, or that part that passes through the cork or wood of the vessel into the interior. *Patent completed.*

3244. W. E. NEWTON. *Improvements in steam generators.* (A communication.) Dated Dec. 27, 1861.

This steam generator is constructed on the principle of injecting a small quantity of water on to a heated metallic surface, thereby flushing it with steam. *Patent abandoned.*

3245. J. MCINTYRE. *Improvements in bomb-shells and similar projectiles.* Dated Dec. 27, 1861.

This invention is not described apart from the drawings. *Patent completed.*

3246. R. A. BROOMAN. *Improvements in steam generators, and in fire-bars employed therein.* (A communication.) Dated Dec. 27, 1861.

This invention relates to a previous patent, dated 5th November, 1861 (No. 2778). The first improvement consists in a new form of joint for closing the aperture made in the fire-box for connecting the water vessel in the fire-box with the water and steam spaces in the boiler. The second improvement consists in carrying the pipes and the joints whereby communication is effected between the said water vessel and the boiler proper outside of the fire-box, and in providing plugs which admit of removal, for allowing the insertion of tools for cleansing the interior of the water vessel. The third improvement consists in an arrangement of fire-bars in steam boiler furnaces. The joint consists of a plate or tube with double flanges. The plate or length of the tube occupies the space between the fire-box and the outer skin; one of the flanges is rivetted to the fire-box and the other flange to the skin. The water vessel is connected to the outer flange, and is independent of the fire-box, with the sides of which it does not come in contact, and, as before stated, the connecting joints to the boiler proper are all made outside of the fire-box. The fire-bars are composed of fixed and moveable bars, the ends of which overlap. The overlapping ends are supported upon one cross-bar. The other ends of the moveable bars are held upon another support, which is connected by plates to the cross-bar in such manner that they may be made to pivot around the cross-bar; the pivotting is effected by means of levers united to vertical rod under control of the attendant. Furnace bars, arranged as before described, possess the advantages of exposing along their whole length spaces for the admission of air between them, while the moveable part allows of the discharge of the fire, of the clinkers, and other residue when required. *Patent completed.*

3247. J. J. H. FAJOLE and P. A. AGOSTINE. *An improved composition or improved compositions suitable for painting, varnishing, and coating.* Dated Dec. 27, 1861.

These compositions are composed of essence of turpentine, caoutchouc, sulphate of zinc, and copal resin in certain proportions. *Patent abandoned.*

3248. J. W. HARLAND. *An improvement or improvements in the manufacture of wood and other types or substitutes therefor, or furniture used by letter-press printers.* Dated Dec. 28, 1861.

This relates to the material of which the types or furniture used by letter-press printers are to be formed, and also to the process of manufacturing the same. The inventor takes paper, or the pulp of paper, which is made from horn raspings or shavings, bone dust, wood shavings, or sawdust, of the same or other substances in a state of communition. A quantity of one or more of the above substances being provided, he saturates it with size or fish glue, or other suitable cement. The material thus prepared is next pressed into a matrix of a form to give it the shape of the type or furniture required. Pressure assisted by heat is next applied, which must be sufficiently great to make the material take accurately the shape of the matrix. This operation being performed the type or furniture is removed from the matrix, and after being dried is (if necessary) reduced to the correct size for being used in the printing press. *Patent abandoned.*

3249. E. LORD. *Certain improvements in machinery for preparing cotton and other fibrous substances.* Dated Dec. 28, 1861.

This applies to the feeding apparatus of openers, blowers, scutchers, carding engines, &c., and consists in supporting the feeding trough or concave plate over which the fleece of fibres passes on a centre; the trough is acted upon by a weight or spring, the object of such weight or spring being to press the fibres between the trough or plate and the feed roller, so as to prevent the fibres being drawn forward unevenly by the beater or licker-in, or other revolving drum or roller acting upon them. *Patent completed.*

3250. A. WARNER. *Improvements in the manufacture of hollow articles for military and war purposes.* Dated Dec. 28, 1861.

This consists, 1, in manufacturing hollow, cylindrical, or other forms, with a bottom thereto, from discs or flat pieces of zinc or tinned zinc, each of such hollow forms being raised or produced from one pillar of zinc or tinned zinc by any of the well known processes for stamping, raising, pressing, or "spinning" metals used in the manufacture of hollow metal articles for other purposes. These hollow forms of zinc or tinned zinc thus produced may be made up into oil bottles for millitary purposes by closing the upper part and applying a suitable stopper thereto, screwed or otherwise secured thereon. It consists, 2, in making boxes for containing the fuse used for the use of artillery from paper lined or otherwise with lead or tin foil. *Patent completed.*

3251. M. HENRY. *Improvements in fire-arms, and in adapting bayonets or cutting or piercing weapons thereto.* (A communication.) Dated Dec. 28, 1861.

This invention relates, first, to breech-loading fire-arms, and its principal feature consists in the employment of an improved breech, which the inventor calls an oscillating breech, by which he means a moveable breech, or capable of being oscillated, rocked, turned, or worked on a fixed fulcrum. *Patent completed.*

3252. J. P. DORMAY, J. S. AIKENHEAD, and S. JOHNSON. *Improvements in the construction of boats for sailing or rowing.* Dated Dec. 30, 1861.

The object here is the attaching or jointing the planking or skin of a sailing or rowing boat, such improved mode being styled by the patentees "flush clenchwork," with bent timbers or ribs, formed by preference in one length or, piece from gunwale to gunwale, so as to obtain great strength combined with extreme lightness and neatness. For this purpose, instead of the edges of the planks being put together square and then caulked, as hitherto practised in building "carvel boats," each edge of each plank, according to these improvements, is bevilled and fitted together, then nailed and clenched at certain intervals, a washer being placed by preference over the point of each nail before clenching it, by which not only a flush or smooth skin is obtained to the boat, but great strength secure joints without caulking, lightness, less resistance in passing through the water, and more correct outline is obtained than by the methods in use for this purpose; and in the application of these improvements to boats of light construction great advantages are derived owing to the facility with which they can be repaired. They prefer to steam or heat the planks in order to shape or form them to the outline of the boat when applying them thereto. *Patent completed.*

3253. J. EDWARDS. *Improvements in the permanent way of railways.* Dated Dec. 30, 1861.

This consists in making railway chairs with an opening sufficiently wide to take the head of the rail. The inventor then takes a filling piece, which fills up the channel of the rail; these filling pieces are placed in the channels of the rail, and the rail is then dropped into the opening in the chair, and is held fast with or without wedging. These chairs are made either of cast or wrought-iron. The invention consists also in making suitable projections in the sides of the rails, which projections fill up the opening in the chair, it being only necessary to drop the said rail into the chair, and it is held fast with or without wedging. Also in placing a cushion of gutta-percha, india-rubber, cork, &c., in the bottom of the chair, so that the concussion is broken while a train is passing, and the bottom of the rail prevented from being injured. Also in making the spike or hold holes in railway chairs obliquely. *Patent abandoned.*

3254. F. TOLHAUSEN. *Improvements in machines for reaping, gathering, and binding harvest produce.* (A communication.) Dated Dec. 30, 1861.

Provisional protection has not been granted for this invention. *Patent completed.*

3255. J. GORTON and B. HENDERSON. *Improvements in the manufacture of ropes.* Dated Dec. 30, 1861.

The patentees claim the use of coal, either alone or mixed with tar in suitable proportions in preparing the hempen yarn of which the rope is made. *Patent completed.*

3256. G. H. BIRKBECK. *Improved apparatus for raising or forcing water or other fluids.* (A communication. Dated Dec. 30, 1861.

This invention refers to a previous patent dated 22nd. Sept., 1860 (No. 2318), and is carried into effect as follows: —Above the water chambers is placed a valve box having three branches, one to each of the water chambers, and the other connected to the pipe leading to the air pump or pumps; within such valve box is a valve, which it is preferred to call the reversing valve, capable (by means of a system of levers and rods) of being actuated by the engine, so as to open or close the communication between the air pump or pumps, and one or the other of the water chambers, the compressed air being directed on to the surface of the water in one of the chambers, so as to displace the water contained therein, and cause it to flow up the up-cast pipe to the height required. When the water has been nearly all discharged from the chamber which is for the time being in communication with the air pump, the engine acts on the reverse valve and causes the compressed air to act on the surface of the water contained in the other chamber, which has been filling with water during the time of the discharge of the contents of the first mentioned chamber. By this arrangement the air in the pipes between the air pump and the chamber, when once compressed, is kept at the density or pressure equal to the weight of the column of water to be lifted. On the top of each chamber an air escape valve is fixed to allow the air to escape in order that such chamber may refill with water. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated May 17, 1862.

1504. C. H. Tessier, Paris, gentleman. A new safety lock. (A communication.)

Dated May 23, 1862.

1559. J. Ward, Radford, Nottingham, machine builder, and J. Dewick, New Lenton, Nottingham, machinist. Improvements in machinery or apparatus for the manufacture of textile or looped fabrics.

Dated May 27, 1862.

1582. C. A. M. Durand, Penjard, St. Andre de Cubzac, France, a new kind of water-mill.

Dated May 31, 1862.

1641. A. Moreau and A. E. Ragoon, Bernard-street, Russell-square. Improvements in electro-magnetic machines or apparatus.

1651. W. E. Newton, 66 Chancery-lane, C.E. Improvements in the treatment of cloth and other textures, leather, or animal tissues, for the purpose of rendering them more durable and impermeable to water and other fluids, and for producing from any firm fibrous texture, such as cloth, cotton, woollen or mixed goods, a durable artificial leather. (A communication.)

1653. W. E. Newton, 66 Chancery-lane, C.E. Improvements in the construction and operation of shot proof gun towers, and the working of the guns therein for sea vessels, floating harbour defences, forts, or land fortifications. (A communication.)

Dated June 4, 1862.

1691. E. Conroy, Boston, U.S., machinist. Improved machinery for cutting cork, bungs, and such like articles.

Dated June 5, 1862.

1695. R. Robinson, 18 Fish-street, Hull. Improvements in fire-escapes, parts of which improvements are also applicable to other purposes.

Dated June 10, 1862.

1725. T. Lister. Hipperholme, near Halifax, plasterer and splint manufacturer. Improvements in the material to be employed for address cards, visiting cards, labels, railway tickets, and other similar articles, whether for printing or writing upon.

Dated June 13, 1862.

1762. J. Bermingham. Cork. Improvements in the construction of vessels of war, parts of which improvements are also applicable to the construction of vessels for commercial and other purposes.

Dated June 16, 1862.

1778. F. M. Lanoa, 4º Boulevart Mont Parnasse, Paris, engineer. An improved geodetic or topographic instrument, intended to combine in one all the instruments now used in surveying.

Dated June 17, 1862.

1792. M. Turner, Wigston, lieutenant-colonel in Her Majesty's volunteers, and E. T. Loseby, Wood-street, City, horologist. Improvements in small arms and ordnance, and in sights for the same, part of which may be used for measuring distances.

Dated June 19, 1862.

1802. W. Clark, Quadrant-road. Highbury-new-park, Islington, engineer. Improvements in the manufacture of that kind of boxes known as dry goods boxes.

Dated June 20, 1862.

1814. W. Jeffries, West Bromwich, Stafford, manager of iron works. A new or improved rail for railways, and a new or improved chair or sleeper for the said rail.

1820. D. Adamson, Newton Moor Iron Works, Newton Moor, Chester, and L. Leigh, Saint Petersburgh, Russia, cotton spinner. Improvements in the construction of steam boilers, and in apparatus connected therewith, part of which is applicable to shipbuilding.

1284. C. Osman, Chryssell-road, Brixton. Improvements in the manufacture of elastic or yielding surfaces for sitting, lying, or reclining upon, part of which improvements are applicable to other purposes.

1826. G. Gray, Whitburne, Linlithgow, N.B., coal and lime master, and D. Cunningham, manufacturing chemist. Improvements in applying a new material to be used as a substitute for the "blackening" or other materials employed in casting or moulding metals.

Dated June 21, 1862.

1828. F. E. Schneider, Paris, and J. Snider, jun., America. Improvements in the construction of breech-loading fire-arms.

1830. J. Taylor, Oldham, cotton spinner. An improved "doffer" or "stripper" for carding engines for preparing cotton and other fibrous substances.

1838. F. Tolhausen, C.E., 17 Rue du Faubourg Montmartre, Paris. Improvements in apparatus for preventing collisions on railways. (A communication.)

1840. J. Lawson, 2 Morris-place, Glasgow. Improvements in the manufacture of carpets and other piled fabrics.

Dated June 23, 1862.

1842. T. Wilson, Birmingham, engineer and gun manufacturer. A new or improved dress fastening, which said fastening is also applicable to the fastening of bands and belts in general, and to other like purposes.

1846 A. Webster, Arbroath, N.B., blacksmith. Improvements in machinery or apparatus for boring slate.

1848. R. Cook, Finsbury-place, South, pianoforte-maker. Improvements in the construction of pianoforte actions.

Dated June 24, 1862.

1852. T. Desgrandschamps, 71 Rue de Charenton, Paris, mechanician. A new mechanism of distribution with motion from the rod, applicable to any kind of steam-engine.

1854. W. Bayliss, flat and chain cable and iron hurdle and fencing manufacturer, Monmore-green, Wolverhampton. An improved strainer for straining and tightening wire for fencing and other purposes.

1856. G. Gray, Greenwich. Improvements in the manufacture of wheels.

1858. W. Clark, 53 Chancery-lane, engineer. Improvements in hernial and other orthopedic apparatus, and in pessaries and other instruments. (A communication.)

Dated June 25, 1862.

1860. S. Brooks, Union Mills, Manchester, machine-maker, and S. Denton, Oldham, mechanic. Improvements in machinery for spinning and doubling.

1862. W. Clark, 53 Chancery-lane, engineer. Improvements in ploughs. (A communication.)

1866. C. C. Steenstruf, Norway. An improved economical can or vessel for containing and delivering lubricating or other fluids.

1870. J. David, 20 Rue St. Fiacre, Paris. An improved dynamometer for ascertaining the relative strength and elasticity of various kinds of threads and ropes.

1872. W. Clark, 53 Chancery-lane, engineer. Improvements in apparatus for raising the nap on cloth and other fabrics. (A communication.)

Dated June 26, 1862.

1874. G. Peterson, Brompton-square, actual counsellor, Russia. Improvements in apparatus for ascertaining the quantity and strength of spirits or other products obtained by the process of distillation. (A communication.)

1876. J. Parkes, London-street, Paddington, gas engineer. Improvements in gas lanterns.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

1894. M. A. F. Mennons, 24 Rue du Mont Thabor, Paris. Improved means for the prevention and reduction of synovial and other swellings or tumours in the limbs of horses. (A communication.) Dated June 21, 1861.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

502. J. Piddington. Shelling or husking grain. (A communication.)

514. H. W. Cook. Propelling carriages and vehicles by means of electricity.

523. T. King and R. Varvill. For controlling the flow of fluids.

524. J. Cliff. Glazing earthenware.

525. W. Miller. Manufacture of sugar.

526. C. L. Knoll. Pianofortes.

530. J. Medhurst. Reefing and furling sails.

532. G. Torr. Manufacturing and reburning animal charcoal.

536. W. Smith. Making cigaretts. (A communication.)

541. J. R. Foster. Manufacture of bullion fringe or cord.

542. W. S. Wood. Regulating the flow of steam.

546. A. W. Makinson and W. F. Batho. Locomotive engines.

547. J. C. Ratliff. Covers or bindings for books.

548. G. McKenzie, W. F. Murray, and J. Hamilton. Manufacture of bobbins.

551. R. A. Brooman. Manufacture of hats and bonnets. (A communication.)

557. M. Dodd. Shearing or cutting metals.

582. W. Conisbee. Colour printing machines.

585. J. Gjers. Moulds for casting.

589. J. T. Smith. Measuring angles.

591. A. J. Sedley. Folding chairs or seats.

592. G. H. Cottam and H. R. Cottam. Horticultural buildings.

594. G. F. Cuy. Electro magnetic motive power engines.

597. J. and R. M. Somervell. Manufacture of boots and shoes.

601. E. Partington. Manufacture of paper.

616. R. Restell. Connecting and disconnecting carriages and engines.

628. P. J. Guyet. Water meters.

642. W. Spence. Projectiles. (A communication.)

643. W. J. Bennett. Solution or preparation to be used with cements.

645. W. S. Nosworthy. Pianofortes.

646. A. Barclay. Traction engines.

690. S. V. Bonneterre, C. T. Erhart, and J. F. Monti. Regulating the pressure of steam.

743. T. Waller, Breech-loading fire-arms.

744. T. Myers. Measuring fluids.

813. B. Fleet. Bottling soda water.

815. E. Morewood and A. Whytock. Coating metals.

825. E. Morewood and A. Whytock. Shaping iron.

830. L. de La Peyrouse. Preservation of animal substances.

899. L. B. Schmolle. Construction of crinolines.

913. H. Smith. Apparatus used when casting iron or other metal.

959. G. Moulton. Engraving rollers.

1078. G. Fell and W. Haynes. Manufacture of leather.

1147. A. Parkes. Manufacture of rollers for surface printing and embossing.

1149. A. Parkes. Surface condensers.

1395. J. Oxley. Mashing and sparging in breweries and distilleries.

1480. G. Haseltine. Churns. (A communication.)

1604. H. Saunders and J. H. Miles. Venetian blinds.

1611. J. Hirst and J. Wood. Stereoscopic apparatus.

1651. W. E. Newton. Treatment of cloth. (A communication.)

1653. W. E. Newton. Shot-proof gun towers. (A communication.)

1657. A. J. Sax. Drums.

1663. J. Whitworth. Shells.

1731. J. Alison. Agricultural implements.

1798. J. H. Johnson. Projectiles. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JULY 18, 1862.

GUNS FOR NAVAL WARFARE.

THERE is hope, at last, of relief for the country from the Armstrong incubus, which weighs so heavily on its finances. Is there another Government in the world, however absolute or despotic, which, during a series of years, would rely for national defence on *one* class of gun, invented, manufactured, proved, inspected, and taken into store by or under the control of one and the same man, who was privileged to dip his hand into the public purse to carry out his schemes for his own benefit, and who had rank and honours bestowed upon him with lavish hand as a recompense for enriching himself and impoverishing the nation, whilst all this time every other gun inventor or manufacturer was excluded from competition and denied even a chance of a fair trial of other classes of guns, which might prove to be better? If a Nicholas or a Louis Napoleon had done such an act, loud would be the outcry amongst our Liberals against the corruption, the jobbery, the tyranny of the Government, which could thus protect a favourite and sacrifice the national interest. There would be dark surmises of connivance with persons in office, and we should bless our stars that there was too much honour and patriotism in public men to render such an abuse possible in this country. We are far from saying that the line of argument we have taken, by way of illustrating in plain terms a national scandal, is strictly applicable to the Armstrong gun contract; but we are quite sure it is high time that the terms of the bargain, and the extraordinary fact that, under any circumstances, it must be enormously remunerative to the inventor, even though his system proved a failure, should be submitted to a searching investigation. It would be hard to find another contract spreading over a number of years under which the Government would be bound to pay a heavy penalty to get rid of a bad bargain. Practically, that is the position in which the War Department stands with reference to the Elswick Company, which is the mechanism for carrying out certain commercial arrangements in which the inspector of artillery could not consistently act in person or in name.

The latest experiments at Shoeburyness have occurred so opportunely to illustrate the conclusions arrived at by Capt. Fishbourne, R.N., of whose paper on "Naval Guns" a preliminary notice appeared in our last number, that we resume the subject in connection with those experiments; and we make no doubt our readers will be satisfied that the terms in which we have deprecated the Armstrong monopoly, and represented the question of naval guns as one highly interesting to the public, are justified by incontrovertible facts and logical conclusions.

We are the more determined to pursue the independent course we have entered upon, when we read in the naval intelligence of the "Times" that "it is ordered by the Admiralty that in "all cases gun-boats shall be furnished *ex-"clusively* with Armstrong guns." Our province is to give a popular exposition of a system of naval guns, based on scientific data, to an extent sufficient to satisfy the professional as well as the general public; that the statements we make are not simply periodical records of the results of experiments, but facts which may be relied upon to regulate the decision of the Legislature in the matter of expenditure on the national defences.

In the words of Captain Fishbourne, "the "question is one of great importance, in an "effective, an economic, and commercial point "of view;" and we may add, that in a mechanical and engineering point of view, it finds an appropriate place in our columns.

In the popular view of the numerous and complex points connected with naval gunnery which it is our duty to present, we will not enter into elaborate disquisitions of scientific questions; but, by stating the conclusions arrived at by contending authorities, we shall render it easy for the unprofessional public to understand the subject.

We find it laid down that "the prime "qualifications for good naval guns are:—1st. "Great initial velocity, no great part of which "must be sacrificed to the rifling. 2ndly. "Simplicity of construction in the gun and in "all its appointments. 3rdly. Muzzle loading, "for safety with high charges. 4thly. Mode "of rifling to be strong and least injurious to "the gun, or easily injured by round shot or "by any other cause, such as loading, con-"stantly in operation. 5thly. Missiles to be "simple, strong, and least liable to injury." Here we have the science of gunnery made easy, and we cannot do better than follow this programme in our argument. But it is unnecessary to discuss details under each of these heads, for in practice they all resolve themselves into the *first*—"initial velocity." Simplicity of construction, muzzle loading, a mode of rifling which shall be made available for round shot, so as not to offer too great an amount of resistance, and missiles simple and strong in form, are all conditions, ably treated by Captain Fishbourne, which tend to carry the first of the *prime qualifications* of a good naval gun into effect.

Initial velocity means the rate of speed with which the projectile leaves the mouth of the gun at the moment of explosion. Its velocity is then at its maximum rate, and declines every second of time during which it travels through the air. The velocity in all cases is in proportion to the charge of powder, but the intensity of the explosion is determined by the resistance the projectile meets with in making its exit from the gun. A round shot fired from a smooth-bore encounters less resistance than a spherical or elongated projectile from a rifled gun. The object of the rifling is to impart a rotary motion to the shot on its own axis, whereby greater accuracy of aim is attained; and that object is effected by causing the projectile to fit closely, so as to arrive at a minimum of windage, and by obstructing its passage out of the gun either by grooves cut in the bore or projections on the shot. But the greater the obstruction the greater the strain on the gun; consequently, assuming the construction and weight of a smooth-bore and a rifled gun to be the same, the charge with which the latter is fired requires to be reduced. In competitive experiments at Shoeburyness, the old 68-pounder smooth bore was fired with the service charge of 16 lbs. of powder, whilst the rifled 110-pounder Armstrong could only be fired with safety with 14 lbs. of powder. If the charge of the latter were increased it would be at the risk of bursting the gun. Here, then, we have the explanation why the initial velocity of projectiles is less from a rifled than from a smooth-bore gun—*the charge must of necessity be less.* This simple fact, for the purposes of naval warfare, entirely overthrows the profound scientific calculations of Sir William Armstrong, and renders his elaborate and expensive system of construction not only useless but detrimental to the public service. Now that this commonplace view of the question is made public by the inexorable logic of facts, it does seem strange to the uninitiated that science did not prove three years ago what a few experiments on iron plates has placed beyond a doubt. Not to embarrass the reader with the details of official tables, one instance will suffice to illustrate the facts stated. In the trial of the Fairbairn target at Shoeburyness, the comparative force of blow from results obtained by measurement was, with the old 68-pounder 5·06, with the Armstrong 110-pounder 2·25, or more than double the effect in favour of the former. At every trial the penetrating and smashing effect of the 68-pounder smooth-bore was found to be considerably greater than the 100-pounder rifled gun. And then it was that Sir William Armstrong, in a carefully elaborate defence of his system, addressed to the "Times," had the simplicity to enunciate for the first time the great truth, that the penetrating effect of a projectile was in proportion to the charge; and the "Times," in a leader, solemnly repeated this truth as a grand discovery. But surely the inventor and the Ordnance authorities ought to have known the fact before they entered on the extravagant course of speculative construction of a new kind of gun.

Sir William Armstrong, after taking two days to prepare his defence and refute Captain Fishbourne's statements at the meeting at the Royal Service Institution, delivered an address which is an admirable specimen of special pleading. He cannot deny the damaging fact of the superior penetrating effect of the 68-pounder smooth-bore, as demonstrated by the figures 5·06 and 2·25, but he declares that "these are "not the usual indentations by any means," and he says, "if we are to take particular in-"stances, there is a target at Shoeburyness, on "which, at 200 yards, the 110-pounder pro-"duced a greater effect than the 68-pounder." Now, the reference to this "particular in-"stance" is hardly candid, because it refers to Mr. Hawkeshaw's laminated target, which, from the defective nature of the system, and having no backing, offers so little resistance, that the pointed and elongated Armstrong bolt, 7 in. in diameter, pierced through the plates more readily than the round 8-inch shot. If there had been any effective resistance, the point of the cone of the Armstrong bolt, which breaks off at the moment of impact, would have produced little or no smashing effect. Sir William then, exercising the skill of the special pleader, travels out of the record, and suddenly shifting the ground of the argument, abandons short ranges, and discourses scientifically on ranges of 670 yards and upwards. This is adroit, but it is not logical. No, Sir William! The question under discussion is the comparative effect of round and rifled projectiles at short ranges, and the particular range referred to is 200 yards, which is a *maximum* distance for ships in action. It is no answer to tell us that at long ranges round shot lose their velocity rapidly, while rifled shot maintain their velocity more effectively. Nor does he point out, what in fairness he ought to have done, that just at the point when the velocity of the two kinds of projectiles is equal and that of the round shot declines, the penetrating force of both is so much reduced that they are innocuous against armour plates. We are talking of the best gun for *naval warfare*, and we have settled the point, that the best gun is that which will produce the greatest effect at short ranges not exceeding 200 yards. It is futile to inform us that for long ranges the rifled gun

has the superiority. True, it carries farther; and for explosive missiles, and especially for field service, there is no denying its advantages, but that is not the point in this discussion. We think it needless to follow Sir William in his defence of the mode of construction of his gun and of the merits of the coil system — *a great fact*, recorded in our last impression, has rendered these points of minor importance. The breech of the 150-pounder, which was said to be an improvement in solidity of construction on the 110-pounder, was blown away. The "Times," prompted, we suppose by the inventor, attributes this misfortune to the gun having been weakened by being fired with a charge of 90 lbs., but that is sheer nonsense. Every gun must be proved, and if it is shaken by the proof, the gun is worthless. The truth is, the construction is defective in principle — it is a mechanical blunder — and we sum up as we began, by saying, "happily for the finances of the country, the prestige of the Armstrong gun is gone." The Minister for War admits that fourteen guns of the same size are ordered; but we cannot doubt that their completion will be suspended.

By a natural transition we pass to the question of floating batteries. In discussing the subject of naval guns, it is impossible to separate the defence from the attack. The power of guns to penetrate or damage the sides of an armour-plated ship must be measured by the force of resistance as well as by the force of impact. It is manifest that the destructive effects of projectiles in future naval warfare will be determined by the strength of the structure to be destroyed.

Reverting to the principles enunciated in this journal for the construction of naval armour, we resume the question of advanced forces for harbour defences.

It is marvellous how the intelligent British public is misled and imposed upon by official assurance and pertinacity, and it is no less surprising that journals which affect to lead public opinion, influenced by political bias, lend their aid to uphold a palpable deception. The Plymouth Sound Fort question rests on absolutely the same foundation as that of the Spithead forts. The point in both cases is whether the defence of the channel leading to the harbour should be a fixed or a floating battery. The few independent members on both sides of the House, who really understood the question, conclusively proved in the debate on the Spithead forts, that it would be waste of public money to erect forts for hypothetical guns, which, if ever they should be produced, could not damage an iron-clad ship at 1,000 yards, and they carried the house with them. On the vote for the Plymouth Sound Fort, Sir John Hay, the chairman of the Iron Plate Committee, who of all other men ought to and does understand the question in all its bearings, pursued the course we ventured to recommend last week. Speaking authoritatively, he showed that at a range of 200 yards no existing gun could stop an iron-clad ship, and that, "according to the most sanguine calculations, not even the 600-pounder about to be made could penetrate the sides of a ship like the Warrior at the distance of 800 yards, which would be the shortest range a hostile vessel entering Plymouth Sound needed to approach the proposed fort; and, moreover, that at a distance of 2,000 yards from it, vessels might take a position to do all the mischief they intended." He pointed out that the only witness recently examined by the defence commission, stated that the intended fort would make an excellent coal depôt, and he derisively remarked, that it was for such a purpose the public money was to be spent, and concluded by maintaining that the sum intended to be thus misapplied should be appropriated to the construction of floating batteries.

Here is an array of sound arguments, not advanced in a spirit of partisanship, but calmly adduced by the chairman of a Government committee, whom the Secretary of the Admiralty so warmly eulogised as a distinguished naval officer of great scientific knowledge, and who, it may be presumed, uttered the sentiments of the committee over which he so ably and impartially presides. And yet this evidence, precisely similar in its facts and conclusions to that which condemned the Spithead forts, is set at naught by the ministers, who, to save themselves from another parliamentary defeat, make a party question of a serious point in our system of naval defence, and induce their adherents to vote away a large sum, which might as well be thrown into the sea, as applied to the construction of a fort inside Plymouth Breakwater. The flunkeys of the press, true to their policy of allegiance to the powers that be, join in chorus to blind the public, and we find on the same day a contemptible attack, in the "Times" and "Daily Telegraph," on independent members who do their duty, the latter journal unblushingly taxing them with an unnatural combination to turn out the ministers and take their places, hypocritically advising that "the electors should begin to watch the way in which some of their representatives do business." The advice is good, but it applies not to those honest members who defend the national purse, but to the system of obstruction and mystification in Government departments, and the corrupt influences in the House of Commons, which render fiscal reform almost hopeless. Let the electors bear these matters in mind, and, when the opportunity of exercising the franchise again occurs, let them exact from candidates a pledge to support administrative reform.

SEWING MACHINES IN THE INTERNATIONAL EXHIBITION.

THE Sewing Machine, to use the phrase of our American friends, has become an "Institution" among us. It is now clearly established that, whatever a needle can accomplish, the machine can do, from the finest and most delicate fabric for female adornment to the heaviest and coarsest habiliments of the sturdy labourer either at home or at the antipodes. There is no doubt that, with respect to sewing machines, many obstacles which bar the progress of a new invention have yet to be overcome. Until lately, there were many persons who never heard of a machine for sewing, and many more who had never seen one. The possibility of any machine doing the minute and exact stitches which needlework by the hand performed, was scarcely entertained; and the most credulous could hardly believe that sewing in any fashion could be done by a needle with an eye at its point.

There were three sewing machines in the Exhibition of 1851. In the Paris Exhibition of 1854 there were fourteen. Professor Willis, in his report of the latter, divides the machines there exhibited into four classes: —

1st. Those wherein the needle is passed completely through the stuff, as with the common sewing needle. These were for embroidery;

2nd. The "crochet," or chain-stitch machine;

3rd. Two-threaded machine, of which one produces the shuttle-stitch; and

4th. Two-threaded machines producing the double chain-stitch.

A machine of the first class was invented and patented in England by John Duncan so far back as 1804. This machine, though intended only for tambouring, had about it something that was suggestive of the sewing machine, and subsequent improvements, such as the eye-pointed needle, brought it nearer to the present perfection of that machine. Stone and Henderson had also patented a machine of the same character in France, in the same year. Several successive attempts to construct a sewing-machine were made both in England and America, of which the principal were Bostwick's in England, and Thimmonier and Hind's in America. But in 1844 a machine was devised by Fisher of Nottingham, which merits some consideration. It raises, in fact, the interesting and important issue: Is the sewing machine an American or an English invention? In a MS. work which we have seen on the "History of the Sewing Machine from the year 1750," by Mr. N. Salamon, and which we hope that gentleman will yet give to the public, the question is thus stated: — "Unquestionably must be awarded to John Fisher, jun., of Nottingham, the rare merit of having originated and invented the combination of threads known as the 'shuttle-stitch,' and the 'interlocked,' or 'chain-stitch;' and there can be little doubt that, had he at that time intended a sewing-machine, he could easily have added, as he did at a later period, the required mechanism for 'feeding' and 'tightening' the stitch. But he was working on the elaboration of a lace-machine — in all probability, the idea of a 'sewing' machine never entered his head — and an exquisite and wonderful lace-making machine he produced, but a lace-making machine only. The praise due to him for his invention, which evinced great genius and mechanical powers of the very highest order, is greatly enhanced by the fact that he was only in his nineteenth year when he perfected it, and there were in it 19,000 separate pieces of mechanism." Mr. Salamon goes on to compare the machine of Fisher with that of Howe, and awards to the latter, what no one will be disposed to refuse him, the credit of having been the first to construct, for all practical purposes, the sewing machine — the one on which all subsequent improvements and modifications have been founded.

It was in the year 1840 that Howe first set himself seriously to construct a sewing machine; and in a lonely garret in Cambridgeport, Massachusetts, during the intervals of labour at his trade and through the hours of the night, the young enthusiast gave his unremitting attention to what had now become the great object of his life. After five years of such toil, he had constructed and finished the first automatic sewing machine for practical purposes. Mr. Salamon, to whom we are indebted for much interesting information about the early struggles of Howe, says: — "A wonderful piece of mechanism to issue from such a workshop! and the triumph of its completion a fitting reward for the genius that had conceived it, and the ingenuity that had carried it to perfection." To test the operating power and practical utility of the invention, two suits of men's clothing, of fine broadcloth, were made by the machine in July 1845; that is to say, all the seaming and stitching work was performed by it, and was

done well and firmly. The stitches, known as the lock-stitch, were made at the rate of one hundred and sixty in half a minute, the average rate of hand-sewing being about thirty stitches in one minute. The machine afterwards, when taken to Boston, obtained even a higher rate of speed. It was worked there daily for two weeks, in a room where some twenty persons were engaged in sewing. They brought portions of their work, such as coat-seams, to the machine to be worked, and the machine did it better and faster than they could have done it themselves. The machine was, in fact, pitted against five girls, the best and quickest workers in the establishment, each girl having one piece of cloth and the machine five pieces, all of the same length, and the seams, which were the inside seams of coat sleeves, also of the same description. The girls sewed much faster than they were in the habit of sewing, and at a rate which they could not have maintained for a day, or even for an hour; but they were beaten by the machine, which was operated by Howe himself and worked by hand. The seaming made by it was the neatest and strongest, and fit for any use in the trade. After going through many struggles and enduring great privations, unhappily the entangling embarrassments of many men of inventive genius, Howe arrived in England in 1847, only to encounter fresh difficulties. His invention had been previously disposed of for the ridiculously small sum of 250*l.*, and patented by Mr. Thomas on December 1, 1846; and Howe came to England, with ulterior hopes, no doubt, but ostensibly to work for the patentee on the construction of his machines at the weekly wages of three pounds. We need not follow him through the bitter disappointments and the prostrated hopes, so well detailed by Mr. Salamon, of his two years' sojourn in England. He returned to America a steerage passenger on board an emigrant ship, and arrived in New York in April 1849, with half-a-crown in his pocket. He soon procured employment as a journeyman machinist, but a letter from his native place in Massachusetts soon sent him thither, where he arrived in time to see the last of his wife, who died in his arms. After his return to America, he became involved in considerable litigation to defend the rights of his American patent. This being decided in his favour, he obtained the power of granting licenses in 1853, but for the following year only fifteen were issued by him. In the five years after, no fewer than 46,023 were granted, and up to September 1860 he had issued 130,000, producing him a net return of nearly 90,000*l.* The chequered life of such a man is in every way most interesting, and we hope yet to see his biography taking its place among others in illustrating the power of self-help, and encouraging other aspirants for distinction amid the tortuous and discouraging part of their career.

Of several other sewing machines patented since Howe's, we may notice Morey's in 1849, who introduced the feed motion, and which is really the groundwork of the present perfected machine. This patent embraces five different machines or modifications. Then there was Hughes, who patented, in 1852, what is now known as the "Lancashire Machine," the feed motion of which was a combination of vertical and horizontal motions, enabling the cloth to be more easily guided by the hand of the operator. In the same year, also, Mr. Belford took out several patents for improvements in sewing machines. Judkin's also was patented in the same year, for improvements which consisted in a vibrating needle, horizontal traversing shuttle, and serrated feeding bar. Dirck in 1853 has a patent for improvements, and, in the same year in America and England, Johnson and Thomas respectively have patents for some novelty, the latter being for a needle and shuttle machine adapted for large manufacturers, the feed motion being based upon that of Hughes. In fact, since the date of Mr. Thomas's patent for Howe's invention, more than 250 patents have been granted in England for "improvements in "sewing machines," a vast majority of which lie buried in the grave of forgotten hopes and misdirected application.

Two years ago, in the pages of this Magazine, we urged upon the machinists of this country to turn their attention to the manufacture of sewing machines, as we foresaw in that an extensive and profitable employment. Just see what they have done in America. In the work by Mr. Salamon, which we have already quoted, he says: "The amount of "property invested in the manufacture of "sewing machines is moderately computed at "$2,000,000. The employment of this capital "provides work for about 8,000 men, besides "an estimated number of 2,000, who are en-"gaged in making machine needles. This is a "business quite distinct from the manufacture "of machines, and is, of course, an entirely new "branch of industry. Another new employ-"ment created by sewing machines, is that of "making machine twist. In introducing the "machines into the tailoring business, much "difficulty was at first experienced, owing to "the want of this necessary article. There are "now numerous manufactories in the United "States exclusively devoted to its production. "They import the raw silk, manufacture it into "twist, and give employment to a great number "of operatives, *chiefly females*. In New York "the sewing machine may also be said to have "created the business of japanning, for all the "machines require to undergo that process. In "1850 there were in that city only two ja-"panners, in a small way of business; there are "now several large establishments employing "a great number of hands."

And then, too, in a purely economical view, the social aspect of work and wages has been marvellously bettered. The number of workmen and workwomen employed since the introduction of the sewing machine has greatly increased. Their wages are much higher, while their hours of labour are considerably reduced. Women especially worked at stitching by hand early and late; now their time is regular, and does not exceed nine hours a day. In the tailoring and clothing business the beneficial effects of sewing machines are very great. On the first introduction of the machine into the trade, the operative tailors combined against it; but as the "outsiders" began to use the machines rather extensively, the regular tailors found themselves forced to adopt it, and the machines are now used more or less in all kinds of tailoring work. The consequence has been that the trade has vastly increased, and the quality of work is both more durable and ornamental than it could possibly have been rendered by hand sewing. The machine has enabled hundreds of tailors and seamstresses to continue at their trade who would have had to turn to something else on account of their sight failing; and hundreds of others, whose health would not admit of sitting a sufficient number of hours to earn a livelihood at hand-sewing, can make a comfortable living by using the machine. To illustrate the advantage resulting to capital from its use, it may be stated that one firm in New York estimate their annual saving in this respect at $75,000. In shirt-making, which is a business largely carried on at Connecticut, one maker employs 400 sewing machines, supplying work for 800 women and 50 men. They make 800 dozen shirts per week. The women earn from $4 to $7 weekly, being one-fourth more than they could earn by hand. The demand for female labour in this branch of industry has been greatly increased by the sewing machine. The mantle and cloak manufacture of the United States is another important branch of female labour which has received great expansion by the sewing machine. In the single city of New York the amount of business done is estimated at $3,000,000 yearly. One machine can do the work of six females, yet, notwithstanding, the number of sewing hands has been greatly increased, additional labour being required to prepare the additional work, and also to finish such parts of it as the machines cannot do. The wages in this trade have also been increased; and, as in the tailoring business, while a greater amount of work is put into the articles made, the cost to the public has been actually less. Hand-sewers earn $4 per week and machine-sewers about $7. The operatives prefer working by machine to working by hand, as it has proved more conducive to their health; and, in fact, it is the delicate females who are chiefly employed on the machines. It may be stated that, in fine sewing, the machine will do the work of four women; in coarser kinds of sewing it will do the work of six women. In fine stitching shirt fronts, it beats hand labour in a much greater proportion. The needlewomen all testify that the introduction of the sewing machine has not affected them any way injuriously; on the contrary, they get full employment in basting. They earn more money, work fewer hours, and their eyesight is not injured, as it needs must be in hand-sewing, from closely watching their work. Tailors, shoemakers, and other operatives of this class also testify to the benefit which the sewing machine has conferred upon them in this important particular. We understand that in 1860 it was ascertained that the United States, with a population of 25,000,000, had in use, probably, not fewer than 200,000 sewing machines, while in Great Britain there were not more, at the highest estimate, than 25,000. In America the estimated cost of plant used in the manufacture of machines is 400,000*l.*, while in Great Britain 5,000*l.* would, in all probability, be beyond the mark. In America there are several large manufactories, each capable of producing from 600 to 1,000 machines weekly, and employing some 5,000 men.

Perhaps the extensive use of the sewing machine might not be signalised in England by such striking effects as in America; but we believe that its introduction into the family, the workshop, and the factory, is a certainty, and, so believing, we shall consider it our duty to popularise them as much as we can.

We have, on several occasions in this Magazine, described their mechanical constructions and need not repeat it here, save where it is necessary in comparing one machine with another, or where any speciality demands consideration. There are about thirty different machines in the Exhibition, each having, or professing to have, some distinctive peculiarity. What those peculiarities are, we will endeavour to make plain to those who are interested in the subject and will follow us through our review, beginning with the machines in the American Court, then taking those in the Processes Court, and, finally, those exhibited in the French Court.

INVENTORS AND THE ADMIRALTY.

"Lot of Inventors.—In the last three years "590 proposals and plans for the purposes of "shot-proof ships have been sent in to the "Admiralty. They were all referred to the "Controller of the Navy and the assistant "officers of his department, and only 105 of "them reached the further stage of being "submitted to a committee or referee; 37 "are still under consideration." So runs a paragraph in the "Jupiter"—a "medium" through which all inventors and their inventions are some day to be handed bodily over to the tender mercies of the public, without judge or jury. As regards the proposals of the "lot" above referred to, it will be seen that between 17 and 18 per cent. only were submitted to that respectable tribunal before which we have been frequently assured, both in and out of Parliament, *all* inventions or plans submitted to the Admiralty were regularly placed. Out of 590 proposals, it appears only 105 reached the "further stage;" the whole of the remainder simply passing through the offices of the Controller of the Navy and his assistants. That these 485 proposals may possibly be all ultimately worthless we do not deny, or even that they may not warrant any very high standard of knowledge in those who pronounce them so, and on whose opinion they are forthwith shelved; but it would still be very interesting to the great body of inventors to know whose plans have been passed to the Committee of reference, and whose throttled in the Controller's offices. If four-fifths of the plans submitted to the Admiralty are so crude, or otherwise worthless, that they can be readily disposed of in the Controller's office by assistants, we cannot help thinking their examination by two or three members of the Committee would involve no serious loss of time, and certainly be far more satisfactory to those giving themselves the trouble to send them in.

We have no doubt whatever that the gentlemen in the Controller's office are men of ability, and desire to fulfil any of the duties required of them with perfect fairness; but we look upon it that a tribunal above all suspicion, and one organised, after considerable delay, expressly to consider propositions made to the Admiralty, should exclusively be employed to decide upon their merits. It would almost seem that the Admiralty have a pleasure in courting criticism on their mode of doing business. They have been assailed so often, and so vigorously, and to a great extent, at least, in former times, so deservedly, that they appear to have permanently "set up their backs," in expectation of continual assaults. They are, however, greatly in error, if they consider that public journalists have any pleasure in finding fault with them where no fault exists. Our duty is very simple, viz. to find out where abuses exist, and to write against them with the view of putting a stop to them. When this is done, we have done, i.e. when we have written a word or two congratulating all parties upon the change, and encouraging them to continue to make useful reforms in accordance with the spirit of the times.

Why should Government departments be for ever at war with the Queen's subjects? Why should not inventors be able to submit their plans to the Admiralty, or to the War Office, with the same certainty in their being fairly and carefully considered on their merits as they would do to any private manufacturer; with the additional security, that no undue advantage would be taken of the confidence reposed in those to whom such plans were submitted? Is this ever done? Is it rather not notorious that a very large majority of those who have sent proposals to these departments have failed to obtain any straightforward or satisfactory reply to their communications, or have ever received any assurance that their plans have even been looked at? Of course the stereotyped forms of reply are not expected to be believed. Mostly, however, they contain neither matter for belief nor disbelief, but simply inform the persons to whom they are addressed that "my Lords are not prepared" to do so and so. Surely, it is due to those who take the pains to send in plans, or even to put down their thoughts upon paper and submit them to a Government Department, to receive some intimation of their communication having been carefully considered, the reason being assigned for its not being considered to fulfil the object intended. During a very long experience with inventors, we have had to tell many of them that their schemes are worthless; but we have never found it difficult in a few words to satisfy them that they are so. If this cannot always be done, they should be put in possession of the grounds upon which an adverse opinion has been found. We say this treatment is justly due to those who send communications to any Government Department, and, unless it can be insured, we are not satisfied but that it would be better to refuse to receive suggestions altogether; or, what would do as well, let it be publicly known that no communications would be attended to at all. This would be honest, at all events, and give the public a notion of the treatment it might expect from its servants.

We sincerely wish we could induce the Admiralty and other Government departments to treat all inventors as they occasionally do some of them: it would be very easy and involve very little, if any, additional trouble. Let them submit *all propositions* to a competent committee, composed of gentlemen, not fettered in their judgements by trade interests of any kind; and let them communicate to the authors of such propositions the decisions of such committee and the exact words used by them. By these means would they obtain the confidence of all persons, and we should soon cease to see the Parliamentary mouthpieces of the several departments so often on their defence. We are not aware that any valid objection could be urged against the publication of a yearly report, giving in outline the various propositions submitted to the several departments, with the decisions and names of the members of the committee to whom they were submitted.

THE IRON WALLS OF OLD ENGLAND.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Letter 17.

The name of inventors of naval armour is legion. No branch of engineering ever produced such a crop of plans. Hundreds, it was stated in the House of Commons, had been addressed to the Admiralty, and the iron plate have had no sinecure. The number contributed by your correspondents is formidable. If all their letters and descriptions, many illustrated by diagrams, were inserted in the "Magazine," there would for some weeks past have been little space left in its columns for other matter. After a careful examination of the whole, I can select only a few for notice. From this time, if any inventor thinks fit to submit his ideas for "Civilian's" opinion, he must not think himself slighted by being unnoticed. The circle of mechanical contrivances for fastening iron plates to ships is so circumscribed, that every plan now brought forward is a repetition, with some modification in form or arrangement, of well-known methods.

Mr. W. Austin, C.E., of Milford, is a prolific inventor. I am obliged by the terms in which he has addressed me — much more favourable than I deserve. I regret I can only briefly notice his communications, which embrace a number of topics. He complains of neglect in official quarters, and probably not without reason. He has sent plans to the Admiralty for "floating revolving steam batteries," and for "fixing armour plates on "timber sides of ships so as to avoid the "cracking of plates and concussion shock or "damage to ships' timbers." Several distinguished naval officers, whose names I am not at liberty to mention, have, he says, bestowed the highest praise on his plans, and advised him "to push his propositions." He has sent for my inspection "a sectional view of a "timber frigate side, cased with armour plates, "and backed with sand." This idea is by no means novel. It has been proposed by other correspondents of the "Magazine," and also, I have been informed, by more than one applicant to the Admiralty. I confess I am not an advocate for this backing. I do not see how it would be possible, even with the "powerful "ramming proposed," to prevent slip through crevices; and I am quite sure no compression would harden the mass sufficiently to prevent the bulging and fracture of the plate when struck. Sand is proverbially shifting. There is no cohesion among the particles. Whatever may be the powers of resistance of a target, it is idle to suppose that a four or five-inch plate cannot be fractured. The plates may be held on and the frame of the ship be protected from penetration, but under the fire of heavy artillery, holes will be made in plates, and out of those holes the sand backing would run out like the sand of an hour-glass. Mr. Austin has paid a visit to the Prince Consort, just launched at Pembroke, "of which," he says, "he can see they are about to make a mess, "by putting armour plates $4\frac{1}{2}$ inches thick "with through bolts on to the oak planking, "without any infill, so that broken plates and "shattered timbers must result;" and I think he is right. Mr. Austin's method of fastening is to fix bars or bearing plates, as he terms them, with convex surfaces, longitudinally outside and over the edges of the armour plates. To secure these "bearing plates," he proposes "bolts four inches in diameter let in "through the ship's sides." The objections to this plan have been repeatedly mentioned in my letters. The holding plates being exposed to impact and projecting beyond the face of the armour plates, will infallibly be smashed, and the shock or jar being transmitted direct to the bolts, the nuts or rivets which hold the points will be broken off. In recommending the use of smaller plates not exceeding a ton in weight, and made of the best iron, Mr. Austin is in the right track, and if he can aid in inducing the Admiralty to adopt that course, he will render a service to the country. He must not be discouraged by rebuffs, but persevere in claiming a trial of his plan.

Mr. H. E. Hutchins has evinced great ingenuity in contriving two plans, of which he has sent drawings; but they involve difficulties of manufacture and construction which would be, I fear, insurmountable. As one mode of

fastening, bars of iron are to be welded on to the armour plates, and large rivets are to be passed through the latter and serve to connect them, by an iron brace at the back, with the welded bars. The other mode is a complicated system of flanges welded to the edges of the armour plates, these flanges being laid hold of by iron bars, which are bent at sharp angles, and finally fastened inside the skin with nuts of a peculiar construction. No provision is made for backing to the plates, which is a serious matter, for the result of the plan is to leave a hollow space between the armour plate and the side of the ship. The inventor frankly avows that "possibly there would be difficulty "in fastening the backing after the plates were "on." As Mr. Hutchins resides in Essex, he would do well to pay a visit to Shoeburyness, to obtain a little practical insight into the difficult subject he has taken in hand, by observing the effects of heavy guns on iron targets.

S. T. C., of Sydenham, does not propose a plan, but he makes some useful suggestions which, although not new, show he has studied and understands the question. He points out what I have often referred to, that no improvement has been made in constructing iron ships so as to give sufficient strength to the structure to carry the heavy weight of armour plates; and thereby he proves that he is, what he says he is, a practical man, having much experience in iron ship building. He observes that the construction "of iron ships should be so ar-"ranged that every piece of metal added to "her should give strength, and that a ship "can be constructed on an improved principle, "which would comprise all the requisites "wanted, combining great strength with light-"ness;" but he does not give his plan of construction.

Mr. E. J. Richardson has patented a mode of constructing armour for ships on the principle of deflection, which he has embodied in the shape of a veritable colossal shield on the classic model of the ancient Greeks, which might be borne by a Titan Ajax, or Achilles. Mr. R. is quite right as to the law of deflection; but the experiments of the iron plate committee tend to prove that the advantages of deflection are obtained by extending the surface of the plate in proportion to the diminution of thickness; so that after all, to attain a given perpendicular height, the weight of the angulated plate will be the same as the vertical plate to resist a given force. Hence no advantage is gained in weight, whilst the angulated form involves great difficulties of construction. Besides, cannon balls at high velocities have an ugly way of their own of penetrating iron plates and smashing fastenings, which seems to set all ordinary laws at defiance. Never were men of science so much at fault as they have been on armour-plating questions. The shields represented by the drawings of the inventor's specification look picturesque, but I fear a 68-pounder would spoil their symmetry.

Mr. Robert Aytoun has a magnificent conception. He would form a floating structure of thick plates, welded together at their edges, adding plate by plate to the massive shell of the vessel. The idea is Homeric, and its execution would require Cyclopean powers; but, as he truly says, nothing would seem to be impossible to the workers of iron of the present day. I can only do what the author of this thought wishes—give it currency by noticing the plan, that its practicability may be considered by practical men.

Mr. D. Dawes, of the Viaduct Works, Crumlin, has sent me a well got-up design of a thorough practical nature; but the mode of securing the armour plates is of the class I term frame fastening, and which I consider objectionable for reasons stated in former letters, which it is not necessary to repeat. It is the Plum and Scott Russell method improved, but so much like Mr. Mulley's, of which there is a notice in my last letter, that they are almost identical. Still there is a difference, and I think in one respect an improvement on Mr. Mulley, inasmuch as in addition to riveting the dovetail-headed angle or T iron ribs, which hold the edges of the armour plates, a screw bolt is introduced (passing through the flange of the rib), which draws the plate to its bearing, after it is in its place. I say nothing about the inventor's wood backing, except that it is to be condemned *in toto*, because that it is not an essential part of the plan. If I understand Mr. Dawes's description rightly, he proposes longitudinal frames external to the skin of the ship, to be formed by riveting girder iron to the internal vertical frames. If it be so, he is forestalled by an invention on that principle which is patented; and his idea of using wood as a backing with the grain end on, is also proposed by another inventor, whose plan was submitted to the Admiralty last year, but which, like many other useful ideas on this matter, lies *perdu* in the limbo of the Controller's department. If Mr. Dawes's plan has not been properly understood in the above remarks, the rectification of any errors he may point out will be inserted in the "Magazine."

Mr. W. H. Taylor, of the Hartlepool Iron Works, suggests that vibration might be obviated, and the armour more securely held to the side of a ship, by two or more layers of plates breaking joint and fastened together by a great number of rivets and bolts, about seven-eighth diameter, only six to nine inches apart, giving a large sectional area to the holding power and diminishing the risk of injury to the fastenings by impact. The same idea occurred to other persons, of whom Mr. Hawkeshaw, the eminent engineer, is one. Under his direction a large target was constructed on that plan, one part being six inches and the other nine inches in thickness. On trial, the result was a complete failure. The number of perforations in the plates proved to be a source of weakness. The shot encountered little resistance; the iron laminæ which made up the thickness of the target yielded successively to the force, the lines of fracture invariably passing through the bolt or rivet holes. Mr. Scott Russell patented the same method two years ago. These engineers, who are great authorities, are not exempt from fallacies. Mr. Taylor will be consoled by finding himself in such good company. In one of my letters there is a description and diagram of Mr. Hawkeshaw's plan.

The plan proposed by Mr. Bertram Mitford, of Cheltenham, of two series of dovetailed plates fitting into each other, one at the back and one at the front; the former, fastened with bolts or rivets to the skin plates, and holding the latter, was patented by Mr. Lancaster, the gun maker, of Bond Street, and proposed for trial by the Admiralty, but abandoned as impracticable.

C. F. T. Y. is welcome to his small *verbal* criticisms. He confirms the law in punching plates, that the power of penetration is limited by the condition that the thickness of the plate must not exceed the diameter of the punch. I acknowledge my error in supposing that C. F. T. Y is equal to a "tour de force;" he is only a "hair-splitter."

Mr. John Rowe's plan, of welding to the back of the armour-plates short tubes, into which holding-bolts are to be tapped, would not answer. They would break off at the thread in the same way as the screw bolts tapped into the back of Mr. Fairbairn's target, which was described in the "Magazine."

Out of a number of other communications two deserve notice, on account of the evidence they furnish of the wide-spread influence of the "Mechanics' Magazine," and of the patriotic sentiment which has induced English mechanics at Melbourne, in Australia, and San Francisco, in California, to contribute their ideas for the protection of the British navy. The former makes some intelligent remarks on elongated and spherical shot for rifled and smooth bore guns. He will have seen this subject fully discussed in your journal since November 15, 1861, which is the date of the last number he had seen when he wrote on April 25. The chief object of the "English Mechanic" at San Francisco is to put his countrymen at home on their guard against the designs of the Americans, among whom he has lived twelve years; and who, he says, "mean, at the first "opportunity, to wreak vengeance on England "for the sympathy she has shown for the "South." He gives extracts from American papers and details, showing the immense preparations making by the United States Government to form an iron clad navy of overwhelming strength.

I now bring my series of letters on "Iron "Walls" to a close. They have attained the object I had in view. They have aided in drawing public attention to the necessity of an invulnerable armour-plated fleet for the defence of this country, and in proving the paramount importance of Government adopting the most perfect modes of constructing iron ships and the armour to protect them. I have to offer my thanks to you, Sir, for inserting my communications, and to a large body of your readers for the kindly manner in which they have appreciated and acknowledged my intentions. My parting word to my countrymen is, "put not your trust in wood." If England is to maintain her independence and command the supremacy of the seas, she must henceforth rely on "Iron Walls Afloat," and make them invulnerable.

A CIVILIAN.

PATENT TOPSAIL SHEET BITS.—Captain Henry Ponsonby, the treasurer of the Conway, a gentleman well known as a scientific seaman, has just patented an invention of practical utility, which is now being exhibited at the rooms of the Mercantile Marine Service Association, in Water Street, Liverpool, of a simple and ingenious construction of topsail sheet bits, which move with the yards, and thus prevent any extra strains either on the slings of the lower yard or topsail sheets when bracing the yards up, as the bits, truss, and slings all work on centres in a perpendicular line. Seamen will see that this simple invention will save very considerable amount of labour, as well as wear and tear, as compared with the old methods of making the sheets fast to bits bolted to a deck beam, reeving the sheets through fixed eye-bolts in the deck or fixed eyes on the mast. By any of these methods, when the topsail is hoisted tight up, the sheets have in all cases to be eased off before the yard can be braced up; thus the benefit is often lost of a *well* set sail in working to windward, particularly in narrow waters. In many cases, under the old plan, the sheets break, or the bolts give way in the deck, and not unfrequently cargo is damaged in consequence. Captain Ponsonby's invention has already been fitted to a ship of one of our most extensive firms, and from its simplicity we are sure will soon become in general application.

An alloy composed of 600 parts copper, 312 of zinc, and 18 of iron, by weight, is said to be very tenacious and capable of being forged.

SOUTH AUSTRALIAN MINES.

Copper has long been the source of South Australia's mineral wealth; and the abundance of it has been as remarkable as that of the gold of Victoria. The principal mines are those of Burra Burra and Jorke's Peninsula. In an account of the colony, prepared by Mr. Frederick Sinnett, of Adelaide, which has just been published, we find that the annual yield of ore of the Burra Burra mine for many years past has averaged from 10,000 to 13,000 tons of from 22 to 23 per cent. of copper; in round numbers, about 2,500 tons of metallic copper, which has been worth to the colony, at the least, 225,000*l.* per annum. Some interesting statistics are given in this little pamphlet respecting the working of this famous mine. The expenditure of the concern within the province since its commencement amounted to 1,640,000*l.*, of which one million alone had been expended in wages. In the year 1859, the number of workmen employed amounted to 1,170; the wages varying, according to the state of the labour market. Common labourers have been paid from 25s. to 40s. per week; miners, from 35s. to 60s.; mechanics, from 42s. to 112s. per week. The Kapunda mine had been steadily worked for years, with handsome results. The first smelting furnace commenced work in December, 1849; but, in consequence of the superior attractions of the gold-fields of Victoria, in the year 1852, causing the men to desert the Kapunda copper mine, the works ceased, and were not resumed till the year 1855. At one time there were only four miners employed. The ores comprise almost every variety, as yellow ore, or pyrites, blue and green carbonates, muriates, grey and black sulphurets, oxides, bell-metal, and peacock ores, and native copper or malleable. The percentage varies much, from 66 downwards. The entire quantity of ore raised from the commencement to the close of the year 1861, was 35,280 tons of 21 cwt., and of an average produce of twenty per cent.

Time only could show whether the mineral wealth of the far north or that of Jorke's Peninsula would be most considerable. How far inland over the surface of Jorke's Peninsula the valuable lodes run is still uncertain; but, even if all the 27,000 acres of mineral claims were to prove available, the greatest distance of land carriage to which the ore would be exposed would be about fifteen miles, as the average width of the entire Peninsula does not exceed twice that distance. It was, however, certain that by far the greater majority of the claims which were so hastily taken out were destitute of copper. The immense yield of the shafts belonging to a Mr. Hughes was no sooner ascertained than sections in the neighbourhood were taken out in the quite vague hope that they might prove equally productive. The mania was, however, a short-lived one, and over many a mile of Jorke's Peninsula, innumerable survey-pegs in the scrub speedily became the only memorials of the excitement that had swept over the district.

The original Wallaroo mines have, however, been so productive as to have entirely changed the face of that part of the country. Two rapidly rising towns, of a population of 3,000, are established where, little more than two years since, there was nothing but a solitary sheep station.

The Moonta mines have also been successful; the ore raised being of a higher percentage than at Wallaroo. Near the surface the ore is chiefly green carbonate, mixed with clay; but at seven or eight fathoms depth it changed to black and yellow ore, interspersed with large lumps of metallic copper, some of them several pounds in weight. The first discovery of these rich deposits was made in May 1861.

The most successful mine, however, in the Jorke Peninsula has been that of the New Cornwall Mineral Association. The leaseholds of this company include fifteen sections of eighty acres each. Arrangements are made for the erection of ore-reducing works at these mines. The ore will be converted into copper by a process recently patented by Mr. R. V. Rodda. In the International Exhibition will be found specimens illustrating this process.

It is said that the whole of the South Australian colony is highly mineralised, and the mines already discovered are capable of affording employment to a very large additional population.

THE ORDNANCE SURVEY.

CONCLUSION.

The 6-inch maps are engraved in sheets 3 feet by 2 feet, the sheets of each county being made to fit together by the marginal lines, so as to form unitedly, if required, a single plan. For this purpose, the co-ordinates of all the trigonometrical points, and of the corners of the sheets of the maps, are computed with reference to the meridian of a central trigonometrical point in each county. The sheet lines are then drawn, and the trigonometrical points laid down on the copper-plates by their co-ordinates, which is done by a very ingeniously constructed machine. The main features of this contrivance are two scales, placed at right angles to each other, and a tracing point, which is made to traverse in directions parallel to the scales. The photographed plans, being traced on thin paper prepared for the purpose with lamp-black, are fitted down by the trigonometrical points, and sheet lines, to the copper-plates, which have been previously covered with a thin coating of wax. The tracings are then rubbed with a burnisher, by which means the lamp-black lines are transferred to the wax. When the tracing is afterwards peeled off, there remains upon the wax surface an outline drawing, sufficient for the guidance of the engraver, who cuts the work into the copper through the wax ground.

Each engraving to the 6-inch scale contains twenty-four square miles, and embraces the same district of country which is contained in sixteen plans on the $\frac{1}{2500}$ scale; the marginal lines are equivalent to one and a half miles and one mile respectively. The latitudes and longitudes are now engraved on the marginal lines of the 6-inch map, as well as on those of maps of a larger scale. The meridianal point in each county being always a point in the grand triangulation of the kingdom, the latitude and longitude of each part are known with complete accuracy, and from these the latitudes and longitudes for the sheet corners of the maps are easily computed.

The 1-inch maps of Scotland and Ireland are laid down on Flamsteed's projection modified, and the sheets of each kingdom will therefore join together to form one map. This, however, is not the case with the 1-inch map of England, which has not been laid down on any projection, but by the method of parallels and perpendiculars to different meridianal lines in different parts of the country. The plans are reduced in this case for the engraver by the pentagraph, or by photography, from the engraved impressions of the 6-inch map, and the tracings are fitted down to the copper-plates by the aid of points previously scored on the copper, in the same manner as described in reference to the 6-inch maps. The distortion resulting from the projection is quite inappreciable in a small area. On the 6-inch engravings, the hill-features of the country to be represented — as being the most difficult portion of the work — are first sketched in, and then are subsequently drawn by skilful draughtsmen on the reduced scale of 1 inch, for the engravers to copy. The contours on the 6-inch map are of great service to the hill draughtsman in regulating his scale of shades, fixing the proper relative importance of the different features, and for giving the exact form of the top of the hill.

The plans of towns are always engraved on copper, and the scale on which they are engraved being five times that of the plans on the $\frac{1}{2500}$ scale, it is arranged that 25 sheets shall be included in one $\frac{1}{2500}$ sheet. The engraving consists of two processes, namely, direct cutting with the graver or the "dry point," and of etching. The gravers are of various shapes and sizes, suited to the kinds of lines to be produced. Square gravers are used to cut broad lines, and lozenge-shaped gravers for the finer. The dry points and etching points resemble large sewing needles, and are fixed into handles. The graver cuts the copper out, and thus forms a clean line. The dry point used for the more delicate line raises a burr, which of course has to be scraped off.

Etching consists in first covering the surface of the copper plate with a substance known as "etching ground," and composed of a mixture of asphaltum, Burgundy pitch, and virgin wax. The subject is traced on the ground, and with the etching point marked through it, so as to expose the surface of the copper below to the action of aquafortis. This process is continued, until the fainter tints are sufficiently deep, when the acid is poured off, and the plate washed with pure water and dried. An examination is next made, and those parts of the plate which have been sufficiently acted upon by the acid, are painted over with a peculiar varnish, which prevents further "biting in" of the aquafortis. Again and again these operations are repeated, until the darkest tints are sufficiently corroded. The work has then to be finished off in its more delicate details by the use of the dry point.

A very excellent and economical plan of putting in trees, woods, rocks, and numeral figures on the copper plates is practised at Southampton. This consists in the use of steel punches, on which those objects have been engraved, and the effects thus produced are marvellous. Some of the boys, of whom there is a numerous staff at the Survey Office, are indeed exceedingly expert at this duty, and will cover a pretty large area of copper plate, with representations of forest trees of varying sizes, in a very short space of time. Like filemakers, they gain, by practice, a delicacy of touch, which makes them use the small hammer and punches with just sufficient force and no more, to effect the desired object. It is needless to say that a great saving of skilled labour, and consequently of expense, is saved by this arrangement. Much of the writing, also, on the copper plates, is engraved by Becker's Patent Machine. Sands and parks, too, are delineated by a machine fitted with a dotting wheel, the pressure of which, and the intervals between the lines of dots, regulate the depth of tint required.

In this way, then, and with some other minute manipulations, into a description of which it is not necessary now to go, the copper plates are made ready for the next operation — that of printing.

To accomplish this, the ink is dabbed on a plate with a dabber, made of old blanketing, and then wiped over with a cloth dipped in an alkaline solution. Finally it is cleaned by a cloth saturated by water only. In large surfaces like those of the plates for the 6-inch maps, this plan of cleaning is easier and more effectual than the usual mode of wiping by the hand only. The paper for printing is wetted and brushed over to make its surface smooth for the better reception of the ink, and being laid carefully on the plate, the whole is passed through the press, the upper roller of which is coated with three layers of blanketing, and one turn of a cloth called fronting, and which comes in contact with the paper. After printing, the sheets are dried between millboards. They are then put between glazed-boards, and after receiving a considerable amount of pressure in a hydraulic press, they are ready for issuing to the public.

The ink used at the Ordnance Office is composed of a mixture of Frankfort-black, and Prussian-blue. These ingredients are ground together with burnt oil, in a small mill erected on the premises.

We now arrive at one of the most important operations performed at the workshops of the Survey Office, and it is that of electrotyping, for the purpose of obtaining duplicate copies of the copper-plates. The electrotype process has been found eminently useful, not only as a means of preserving unworn copies of the plates, but also as enabling copies to be taken in their different stages of progress. Thus, for example, several classes of infor-

mation may be engraved upon a plate, which, in all other respects, would resemble the original. Distinctive maps as regards boundaries, contours, hill features, and geological lines, are thus obtainable, while all other characteristics remain identical. The value of the electrotype in ordnance mapping, can, in truth, be scarcely over-estimated; and one other especial advantage arising from it is worth mentioning. It is the facility which the process affords for altering engravings. It is much easier to scrape off obsolete details, &c., from the electrotype cast or matrix of an engraved plate, in which they are *in relief*, than to cut them out from the original copper-plate, in which they were *in intaglio*.

The galvanic battery employed at Southampton is that invented by Mr. Smee, and in which the metals used are zinc amalgamated with mercury, and copper silvered and platinised, the exciting liquid being dilute sulphuric acid. The zinc plate, 2 feet, by 2 feet 4 inches, is suspended between two platinised silvered plates of the same size as itself, in a bath of dilute sulphuric acid, one part acid to tw. nty parts water. To each of the silvered plates is attached a bundle of six copper wires, each one-tenth of an inch in diameter, and which are united by a screw-plate, from which there depends a bundle of twelve copper wires, the extremities of which are soldered to a sheet of crude copper, of the same dimensions as the plate to be copied. From the zinc plate also proceeds a bundle of twelve copper wires, which are attached to the engraved plate; this has been previously washed over with cyanide of silver and with a solution of iodine, which latter has been permitted to evaporate in the sun. By these means all chance of the adhesion of the new to the old copper is avoided. A composition of wax and tallow is also laid round the edges of the plate to prevent the deposit of electrotype copper around them.

The engraved and the plain copper sheets are then laid horizontally one above the other, with a space of about one inch between them, in a wooden trough lined with gutta percha. The trough contains a saturated solution of sulphate of copper and sulphuric acid. As soon as this is done the galvanic action commences; copper is deposited on the engraved copper plate, and the zinc plate in the battery-tank commences to be dissolved. The sheet of crude copper suffers the same fate, and as it dissolves, supplies the waste in the sulphate solution occasioned by the deposit of copper on the engraved plate. During the process a gentle rocking motion is given to the troughs by means of a simple piece of machinery put in motion by a descending weight. As soon as a sufficient time has elapsed, the plate is taken out of the trough, and the sheet of copper which has been deposited is removed from the engraved plate, of which, indeed, it will be found to be an exact cast, with this difference, as has been said, that the lines will be in relief. It is usual at Southampton to denominate the resulting plate a *matrix*; we are of opinion, however, that it would be more exact to give the plate to be copied that name.

The same process is now repeated, the newly-made plate this time forming the copy. An electrotype duplicate, and perfectly exact and beautiful *fac-simile* of the original engraved plate is the result. When we witnessed these interesting works not long since, by permission of Sir Henry James, and under the excellent guidance of Colonel Cameron, we were indeed much impressed by the perfection to which the electrotyping process had attained at the Ordnance Works.

The platinised plates, it may be mentioned, are dipped every day into a solution of perchloride of iron, to remove impurities, and the zinc plates are scrubbed at the same time.

When the battery is in good working order, and the engraved plate is laid under the sheet of rough copper, about one-third of a pound of copper to the square foot is deposited per day.

So far as the *modus operandi* of preparing Ordnance Maps, and the means of multiplying them, are concerned, we have thus endeavoured to convey accurate details to our readers. For the opportunity for gaining that information we must admit that we are indebted to a considerable extent t the gallant officers at the head of the Survey Office whose names have just been mentioned. — *From the Building News.*

ON THE PROBABLE CAUSE OF THOSE EXPLOSIONS OF STEAM BOILERS CALLED FULMINATING.

ACADEMY OF SCIENCES OF PARIS.

UNDER this title, a note was presented by M. Mangin, the substance of which is as follows:—

It results from the admirable experiments of M. Dufour, that the temperature of water may, under certain circumstances, be brought to 178° cent. (352·5° Fahr.), without the production of boiling. These circumstances are the insulation from contact with the vessel, and insulation from contact with the air. Ebullition is produced by contact with a solid, that is, by the disturbance of the molecular equilibrium, and there is then a sudden evolution of steam. Nevertheless, every solid contact is not equally efficient in producing this change of state, and it results from the experiments of M. Dufour that isolation from contact with the vessel is not absolutely necessary for the production of the phenomenon. What appears to be indispensable is that the water shall be deprived of air, that the operation shall be carried on slowly, and that the heated mass shall be withdrawn from external disturbing causes. Having explained these preliminaries, let us see how the explosions called *fulminating* are to be explained.

These explosions take place only when the machine has been for a greater or less time at rest, and generally at the moment when they are about to resume the movement of the machine; and the boiler by its complete quietness gives no indication of the event. It is enough to open the throttle-valve, or one of the gauge-cocks, or the door of the furnace or ash-pit, or, in fact, any disturbance of the unstable equilibrium which has been established, to decide the catastrophe. It has also been remarked that, before the explosion, the pressure in the boiler is rather low than high. What, then, has taken place?

When the machine was stopped, the pumps were also stopped; the furnace and ash-pit doors were closed, as were all the escapes for steam or water. The ebullition continued, the safety-valve acted, and the water which had recently been pumped in, was purged from air. Then when the activity of the fire had fallen sufficiently, the valve fell into its seat, and the apparatus assumed a state of repose. If the atmosphere was calm, the draft null, and the escapes of water and steam hermetically closed, the apparatus (allow me to use the figure) has gone to sleep, and the molecules of water being at rest, the temperature has gradually been raised to a point notably above that of evaporation under the existing pressure. As the water produces no steam, that pressure may be and may keep below that necessary for the action of the safety-valve. Things being in this condition, let any cause whatever disturb the equilibrium of the molecules, and all the heat stored up in the liquid mass is instantly employed in producing an enormous volume of steam, while the mass of water not evaporated falls to the temperature corresponding to its pressure.

Figures will easily account for the violence of the explosion which takes place. Let us suppose, in fact, that the pressure in the boiler, before the explosion, was 4 atmospheres, and that the temperature, in the quiescent state of the water, was only 170° cent. (338° Fahr.) As at 4 atmospheres the temperature of the water and steam is 145° cent. (293° Fahr.), each kilogramme of water in the boiler contains 25 units of heat above its normal quantity. Therefore, the moment this heat was liberated, it must have converted into steam $\frac{25}{606{\cdot}5 + 0{\cdot}305 \times 145 - 145}$ or nearly $\frac{1}{20}$th of a kilogramme of water; that is about one-twentieth of the mass of water in the boiler was suddenly converted into steam.

Now, if we suppose that the volume of water in the boiler was double that of the steam, a quantity of water equal to one-tenth of the volume of the steam is suddenly vaporized; and as, at a pressure of 4 atmospheres, 1 volume of water produces 477 volumes of steam, the volume of the steam will be increased 47 times, and the pressure will be 188 atmospheres. It will be conceived that against such generations of steam, the safety-valves are of no effect, and that the explosions are really fulminating.

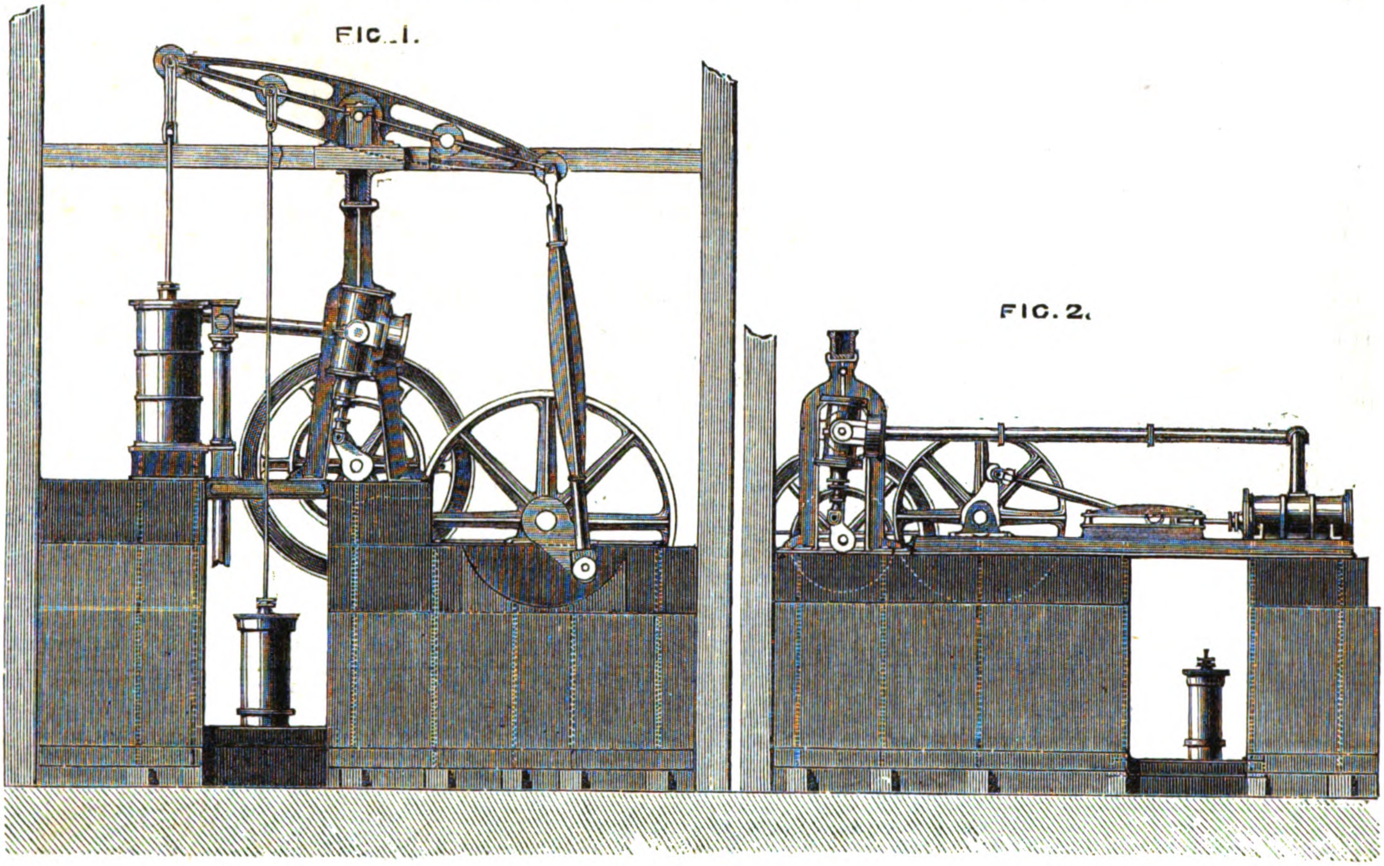
This manner of looking at the phenomenon leads to the suggestion of the following precautions. To prevent the *torpor* of the water, let the boiler be so arranged that there shall be a constant circulation kept up by the difference of temperatures of different parts. A second precaution easily taken is never to close a boiler when at rest, hermetically, but to keep the safety-valve slightly raised, or a steam-cock a little open, so that a small quantity of steam may always be forming.

AN EXPERIMENTAL STEAMER.—NEW METHOD OF PROPULSION.

ON Friday morning last, a little steamer, measuring about twelve tons, and fully fifty feet long, with only a chimney standing amidships, entered our harbour. She is the property of a military gentleman from the Clyde, and is, we understand, a patented invention, protected for a twelvemonth, showing a new method of propulsion and steering. The vessel has no rudder, but is steered — and most admirably and readily steered — by the propelling apparatus. This apparatus is fixed at the stern, and consists of a horizontal iron wheel, from which project six spokes, also horizontal, and attached to the end of each spoke, and dipping vertically into the water, is a blade, working in the same way as the blade of a patent paddle — namely, turning its "feather edge" to the water as it goes forward, but the full flat face when moving in the direction necessary for propelling the vessel. These spokes are made to revolve with the wheel with which they are connected; and this wheel, by an eccentric motion which it possesses, is made to remain fairly amidships, or is moved from port to starboard by means of a lever connected with the internal machinery. She answers to the least touch of this lever; and another remarkable property of the little craft is, that she goes as well, and steers as truly stern first as stem foremost. There is one drawback at once visible on seeing the vessel sailing; the horizontal wheel is fully a foot above the surface of the water, and the bars of the six blades being uncovered, would, in revolving, be very liable to become entangled with drift wood or other floating matter. However, a projecting cover might be made to obviate this. The vessel is chiefly occupied with the furnace and boiler and engine. Her deck is flush, and the only bulwark is a rope netting. She came from the Clyde, bound for Aberdeen. She passed through the Clyde and Forth Canal, and in a mist, early on Friday morning, went half way up the Tay without discovering her error, having lost reckoning after making the East Neuk of Fife. We are told that she has neither anchor nor compass on board. Three blades of her paddle were broken in coming through the canal, which, of course, much reduced her speed, but notwithstanding this, her gallant veteran owner, with his crew of one seaman, a stoker, and an engineer, steamed smartly out of the harbour in the afternoon, standing gaily away to the north; the little craft, not much larger than a large fishing boat, sitting lightly and steadily on the water. — *Arbroath Guide.*

A gentleman, M. Mathieu (de la Drôme), who filled no undistinguished place in the French republican assemblies of 1848, affirms that he has discovered regular tides in the atmosphere, precisely analogous to those of the sea, which reduce varieties of temperature to settled rule, by which the weather can be foretold days, weeks, nay, months, in advance, with scientific accuracy.

WOODWARD'S IMPROVED COMPOUND STEAM-ENGINE

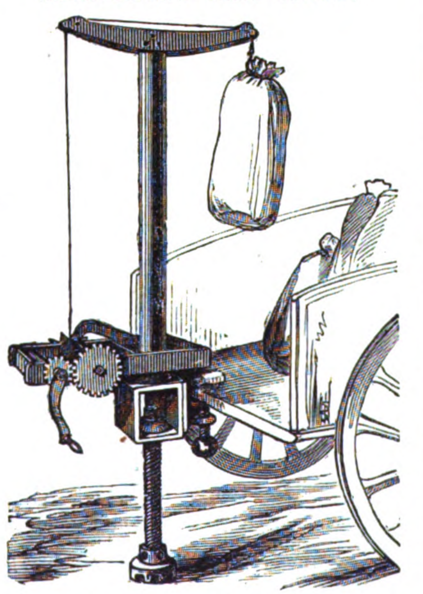


THE above engravings illustrate an invention recently patented by Messrs. Woodward, of Manchester, for improved arrangements in steam-engines. The first part consists in the arrangement and combination of a vibratory or fixed cylinder placed between the pillars of a beam engine, as represented at Fig. 1, or between the pillars and the wall of the engine-house, thereby requiring no additional foundation. The vibrating or fixed cylinder is employed as an auxiliary or pusher to the beam engine, or it may act as a separate engine. In some cases one or all of the pillars of the beam engine are taken away, and a framework of iron substituted, and so constructed as to support the vibrating or fixed cylinder; the other side may be supported by a fixing firmly secured to the wall of the engine-house. The vibrating or fixed cylinder is connected to the beam engine by means of a separate crank, crank shaft, and spur wheels, one end of the crank shaft being carried by the framework, and the other end working in a bearing fixed in the wall, through which it is carried, if required, so as to drive a mill in a separate building. The wheels are made of any desired size or proportion, and the vibrating or fixed cylinder is worked by high-pressure steam direct from the boiler, and the steam after passing through the cylinder passes to the cylinder of the beam engine, thereby forming a compact and efficient compound engine; or the vibrating or fixed cylinder may be connected direct with the condenser of the beam engine, and thus form another arrangement of compound engine.

The second part consists in the arrangement and application of a vibrating or fixed cylinder to a horizontal engine, to act as an auxiliary or pusher to the engine, as represented in Fig. 2. A framing of cast iron, placed at the end of the engine, is constructed so as to carry the vibrating or fixed cylinder, as the case may be; the cylinder is connected to the horizontal engine by means of a separate crank, crank shaft, and spur wheels, one end of the crank shaft being carried by the framework, and the other end working in a bearing secured to the wall, through which it passes if required so as to drive a separate part of the mill, or for any other purpose.

The invention consists, thirdly, in an improved arrangement and construction of the framework for carrying the vibrating or fixed cylinder, so that the power will be contained within the said framework.

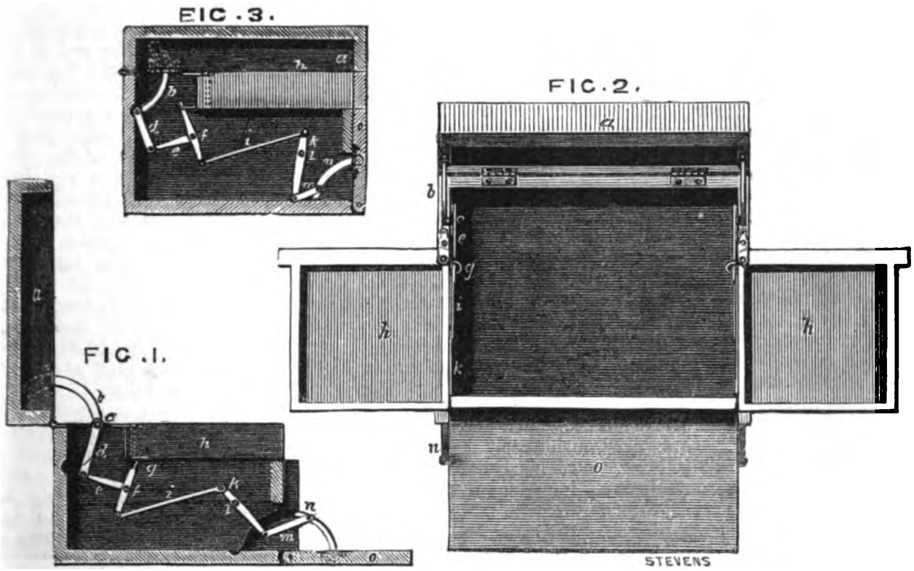
MIDDLETON'S CART CRANE.



THE accompanying engraving illustrates a very useful invention by Mr. David Middleton, of Burton by Lincoln, agriculturist, for "Improvements in cranes for lifting weights into and out of carts, and for other purposes." The engraving shows the crane in perspective as applied to the tail of a cart. The invention consists in mounting, in a convenient frame, a windlass, the shaft of which carries on one side a toothed wheel, in gear with a pinion receiving motion from a crank handle. The other end of the shaft carries a ratchet wheel, into which a paul drops to prevent the return of the drum until the paul is released from the teeth of the ratchet. An upright (by preference hollow) is supported at one end of the frame carrying a cross-bar at top, having guide-pulleys at each end thereof, and over which the rope or chain from the windlass passes. When the crane is used for raising weights from carts, the hollow upright is placed on a strong spindle connected to a foot or support, which is secured by lugs to the cart-tail; a jack screw, the lower end of which terminates in a foot, passes through the base of the support, which, while acting as a support to the cart, also enables its height from the ground to be adjusted to suit any carts or other vehicles to be loaded or unloaded.

NEW TANK LOCOMOTIVE.—The *American Railway Review* says: The tank locomotive named the Monitor, built by Danforth, Cooke & Co., for the Hudson River Railway, has some novelties worthy of especial notice. It has one pair of drivers, five feet, and two trucks; the front truck under the smoke-box, the other under the tank, behind the foot-plate. The coal-box is over the tank; it has an inclined bottom, the tank-top sloping upward to the water entrance. It holds water for about twenty miles. The fuel is Cumberland coal. The chimney is double—the inner chimney being raised or lowered by the engineman, as he wishes to vary the draft. It has two feed-water heaters, situated close behind the smoke-box, which is square-bottomed. The cylinders, judging from sight, are about 10 by 18. We shall, as soon as convenient, obtain the dimensions of all parts of this engine. We hear that its performance is entirely satisfactory, with a train of three first-class passenger-cars. Its usual train is two. It runs the Yonkers train, stopping at all stations, and keeps its time without difficulty.

BETJEMANN'S DRESSING-CASES.



MESSRS. BETJEMANN, of Pentonville, desk and dressing-case manufacturers, have obtained a patent for improvements in dressing-cases, applicable to other cases and boxes, of which the following is the specification:—

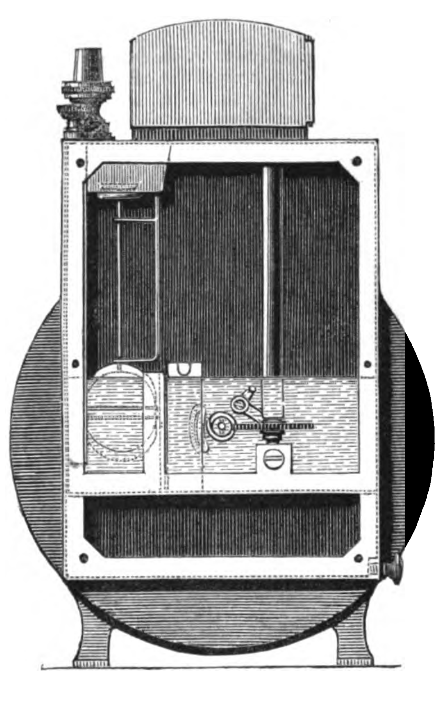
Our invention consists in an arrangement of quadrants, levers, and connecting rods, as hereafter explained, for the purpose of opening or letting down a front flap, and of opening out one side tray at one or both sides of the dressing-case upon the raising of the top or lid thereof. The action may be applied to both flap and side tray, or side trays, or to either separately.

We will suppose our invention applied to a dressing-case fitted with a front flap to let down, and with two small trays, hinged one at each side, to the upper part and sides of the dressing-case, then at each side the arrangement shown at Fig. 1 of the accompanying drawings is that which we adopt. To the lid *a* we connect a quadrant *b*, carry out an arm *c* from the lower part thereof, and by means of a bar *d* connect it to a double crank or ⊥ lever *e* centred on a stud *f* fixed in the side of the case; the upper arm of this lever enters an eye *g* projecting from a metal plate fixed to or inserted in the underside of the tray *h*, or on the side and near the back thereof. The lower arm of the double crank lever *e* is connected by another connecting rod *i* to one arm of another lever *k* centred on a stud *l* fixed in the side of the case, the opposite end of which lever is united by a link *m* to the upper end of a quadrant *n*, the lower end of which is fixed to the side of the front flap *o* near the bottom thereof. If one or both side trays only be required to be moved towards the connecting rod, the other parts of the flap are dispensed with; and, in like manner, if the flap only is to be let down, then those parts for working the side tray or trays are dispensed with.

The parts are so connected that, upon raising the lid, the flap is let down, and the side tray or trays is or are simultaneously opened out into the position shown by Fig. 2, which is a plan view of the case, while on the closing of the lid the flap is folded up, and the side tray or trays is or are also folded inwards, and the whole dressing-case thus shut, when the levers, quadrants, and other parts assume the position shown in Fig. 3.

Instead of the levers being connected to the side of the case directly, as hereinbefore mentioned, they may be attached to a metal plate or plates fixed on the sides of the case.

COCHRANE'S IMPROVED WET GAS METERS.



MR. J. COCHRANE, of Harburn, Mid-Lothian, gentleman, has just patented an invention for improvements in wet gas meters, which relates to their peculiar arrangement, whereby the ordinary existing meters, as well as meters constructed according to this invention, are made to comply with the requirements of the Sale of Gas Act. According to this invention, as illustrated above, it is proposed to surround the present float of the gas inlet valve by a box or partition so as to separate it from the ordinary water chamber of the meter, and to insert the lower end of the water supply pipe into this box or float chamber, in lieu of into the main water chamber as heretofore. By this means the smallest quantity of water which may be fraudulently extracted by a syphon or otherwise through the water supply pipe, will instantly affect the position of the float, and cause the gas to be shut off without affecting, in the slightest degree, the proper water level in the measuring chamber.

ON FORCE.

(*Concluded from page 15.*)

THERE is one other consideration connected with the permanence of our present terrestrial conditions, which is well worthy of our attention. Standing upon one of the London bridges, we observe the current of the Thames reversed, and the water poured upward twice a day. The water thus moved rubs against the river's bed and sides, and heat is the consequence of this friction. The heat thus generated is in part radiated into space, and then lost, as far as the earth is concerned. What is it that supplies this incessant loss? The earth's rotation. Let us look a little more closely at the matter. Imagine the moon fixed, and the earth turning like a wheel from west to east in its diurnal rotation. Suppose a high mountain on the earth's surface; on approaching the moon's meridian, that mountain is, as it were, laid hold of by the moon, and forms a kind of handle by which the earth is pulled more quickly round. But when the meridian is passed, the pull of the moon on the mountain would be in the opposite direction—it now tends to diminish the velocity of rotation as much as it previously augmented it; and thus the action of all fixed bodies on the earth's surface is neutralised. But suppose the mountain to lie always to the east of the moon's meridian, the pull then would be always exerted against the earth's rotation, the velocity of which would be diminished in a degree corresponding to the strength of the pull. *The tidal wave occupies this position*—it lies always to the east of the moon's meridian, and thus the waters of the ocean are in part dragged as a brake along the surface of the earth; and as a brake they must diminish the velocity of the earth's rotation. The diminution, though inevitable, is, however, too small to make itself felt within the period over which observations on the subject extend. Supposing then that we turn a mill by the action of the tide, and produce heat by the friction of the mill-stones; that heat has an origin totally different from the heat produced by another mill which is turned by a mountain stream. The former is produced at the expense of the earth's rotation, the latter at the expense of the sun's radiation.

The sun, by the act of vaporisation, lifts mechanically all the moisture of our air. It condenses and falls in the form of rain—it freezes and falls as snow. In this solid form it is piled upon the Alpine heights, and furnishes materials for the glaciers of the Alps. But the sun again interposes, liberates the solidified liquid, and permits it to roll by gravity to the sea. The mechanical force of every river in the world, as it rolls towards the ocean, is drawn from the heat of the sun. No streamlet glides to a lower level without having been first lifted to the elevation from which it springs by the mighty power of the sun. The energy of winds is also due entirely to the sun; but there is still another work which he performs, and his connection with which is not so obvious. Trees and vegetables grow upon the earth, and when burned they give rise to heat, and hence to mechanical energy. Whence is this power derived? You see this oxide of iron, produced by the falling together of the atoms of iron and oxygen; here also is a transparent gas which you cannot now see—carbonic acid gas—which is formed by the falling together of carbon and oxygen. These atoms thus in close union resemble our lead weight while resting on the earth; but I can wind up the weight and prepare it for another fall, and so these atoms can be wound up, separated from each other, and thus enabled to repeat the process of combination. In the building of plants carbonic acid is the material from which the carbon of the plant is derived; and the solar beam is the agent which tears the atoms asunder, setting the oxygen free, and allowing the carbon to aggregate in woody fibre. Let the solar rays fall upon a surface of sand; the sand is heated, and finally radiates away as much heat as it receives; let the same beams fall upon a forest, the quantity of heat given back is less than the forest receives, for the energy of a portion of the sunbeams is invested in building up the trees in the manner indicated.

Without the sun the reduction of the carbonic acid cannot be effected, and an amount of sunlight is consumed exactly equivalent to the molecular work done. Thus trees are formed; thus the cotton on which Mr. Bazley discoursed last Friday is formed. I ignite this cotton, and it flames; the oxygen again unites with its beloved carbon; but an amount of heat equal to that which you see produced by its combustion was sacrificed by the sun to form that bit of cotton.

But we cannot stop at vegetable life, for this is the source, mediate or immediate, of all animal life. The sun severs the carbon from its oxygen; the animal consumes the vegetable thus formed, and in its arteries a reunion of the severed elements takes place, and produces animal heat. Thus, strictly speaking, the process of building a vegetable is one of winding up; the process of building an animal is one of running down. The warmth of our bodies, and every mechanical energy which we exert, trace their lineage directly to the sun. The fight of a pair of pugilists, the motion of an army, or the lifting of his own body up mountain slopes by an Alpine climber, are all cases of mechanical energy drawn from the sun. Not, therefore, in a poetical, but in a purely mechanical sense, are we children of the sun. Without food we should soon oxidise our own bodies. A man weighing 150 lbs. has 64 lbs. of muscle; but these, when dried, reduce themselves to 15 lbs. Doing an ordinary day's work for 80 days, this mass of muscle would be wholly oxidised. Special organs which do more work would be more quickly oxidised: the heart, for example, if entirely unsustained, would be oxidised in about a week. Take the amount of heat due to the direct oxidation of a given amount of food; a less amount of heat is developed by this food in the working animal frame, and the missing quantity is the exact equivalent of the mechanical work which the body accomplishes.

I might extend these considerations — the work, indeed, is done to my hand—but I am warned that I have kept you already too long. To whom then are we indebted for the striking generalisations of this evening's discourse? All that I have laid before you is the work of a man of whom you have scarcely ever heard. All that I have brought before you has been taken from the labours of a German physician, named Mayer. Without external stimulus, and pursuing his profession as town physician in Heilbronn, this man was the first to raise the conception of the interaction of natural forces to clearness in his own mind. And yet he is scarcely ever heard of in scientific lectures, and even to scientific men his merits are but partially known. Led by his own beautiful researches, and quite independent of Mayer, Mr. Joule published his first paper on the "Mechanical Value of Heat" in 1843; but in 1842 Mayer had actually calculated the mechanical equivalent of heat from data which a man of rare originality alone could turn to account. From the velocity of sound in air Mayer determined the mechanical equivalent of heat. In 1845 he published his Memoir on "Organic Motion," and applied the mechanical theory of heat in the most fearless and precise manner to vital processes. He also embraced the other natural agents in his chain of conservation. In 1853 Mr. Waterston proposed, independently, the meteoric theory of the sun's heat, and in 1854 Professor William Thomson applied his admirable mathematical powers to the development of the theory; but six years previously the subject had been handled in a masterly manner by Mayer, and all that I have said on this subject has been derived from him. When we consider the circumstances of Mayer's life, and the period at which he wrote, we cannot fail to be struck with astonishment at what he has accomplished. Here was a man of genius working in silence, animated solely by a love of his subject, and arriving at the most important results some time in advance of those whose lives were entirely devoted to Natural Philosophy. It was the accident of bleeding a feverish patient at Java in 1840 that led Mayer to speculate on these subjects. He noticed that the venous blood in the tropics was of a much brighter red than in colder latitudes, and his reasoning on this fact led him into the laboratory of natural forces, where he has worked with such signal ability and success. Well, you will desire to know what has become of this man. His mind gave way; he became insane, and he was sent to a lunatic asylum. In a biographical dictionary of his country it is stated that he died there: but this is incorrect. He recovered; and, I believe, is at this moment a cultivator of vineyards in Heilbronn.

June 20.

While preparing for publication my last course of lectures on Heat, I wished to make myself acquainted with all that Mayer had done in connection with this subject. I accordingly wrote to two gentlemen who above all others seemed likely to give me the information which I needed. Both of them are Germans, and both particularly distinguished in connection with the Dynamical Theory of Heat. Each of them kindly furnished me with the list of Mayer's publications, and one of them was so friendly as to order them from a bookseller, and to send them to me. This friend, in his reply to my first letter regarding Mayer, stated his belief that I should not find anything very important in Mayer's writings; but before forwarding the memoirs to me he read them himself. His letter accompanying the first of these papers contains the following words:—"I must here retract the statement in my last letter, that you would not find much matter of importance in Mayer's writings: I am astonished at the multitude of beautiful and correct thoughts which they contain;" and he goes on to point out various important subjects, in the treatment of which Mayer had anticipated other eminent writers. My second friend, in whose own publications the name of Mayer repeatedly occurs, and whose papers containing these references were translated some years ago by myself, was, on the 10th of last month, unacquainted with the thoughtful and beautiful essay of Mayer's, entitled "Beiträge zur Dynamik des Himmels;" and in 1854, when Professor William Thomson developed in so striking a manner the meteoric theory of the sun's heat, he was certainly not aware of the existence of that essay, though from a recent article in "Macmillan's Magazine" I infer that he is now aware of it. Mayer's physiological writings have been referred to by physiologists — by Dr. Carpenter, for example — in terms of honourable recognition. We have hitherto, indeed, obtained fragmentary glimpses of the man, partly from physicists and partly from physiologists; but his total merit has never yet been recognised as it assuredly would have been had he chosen a happier mode of publication. I do not think a greater disservice could be done to a man of science than to overstate his claims: such overstatement is sure to recoil to the disadvantage of him in whose interest it is made. But when Mayer's opportunities, achievements, and fate are taken into account, I do not think that I shall be deeply blamed for attempting to place him in that honourable position which I believe to be his due.

Here, however, are the titles of Mayer's papers, the perusal of which will correct any error of judgment into which I may have fallen regarding their author. "Bemerkungen über die Kräfte der unbelebten Natur," Liebig's Annalen, 1842, vol. xlii. p. 231; "Die Organische Bewegung in ihrem Zusammenhange mit dem Stoff-wechsel;" Heilbronn, 1845; "Beiträge zur Dynamik des Himmels," Heilbronn, 1848; "Bemerkungen über das Mechanische Equivalent der Wärme," Heilbronn, 1851. J. T.

DRAINAGE OF THE MIDDLE LEVEL.

THE *Exchange* says: — The principles on which Telford and Rennie drained the Levels (1826-29) may be briefly stated. There are three essentials to good drainage: — A channel large enough to receive the water; a declivity sufficient to carry it off; and an outfall to the sea or some other body of water large enough to receive it. The channel was provided by widening the rivers and drains where necessary; the declivity, by cutting a straight channel to supersede the old meandering course of the Nene. This last work was rendered imperative by the flatness of the Level. It was demonstrated that water will not flow with the requisite rapidity if its inclination towards the sea is less than four inches per mile in a straight line; and of course every curve in a stream diminishes the force of the current, and renders a greater declivity necessary to prevent the accumulation of water in the channel. The course of the Nene was straightened in accordance with this reasoning; a favourable spot was selected for the discharge of the waters; and the result was that the lower water line was lowered 10 feet 6 inches; 1,500 acres were embanked and brought into cultivation; the value of the land was greatly augmented, and the navigation at Wisbeach wonderfully improved. The works in the North Level were even more successful, for 75,000 acres, of which 15,000 had previously been absolutely worthless, were raised to a value of 50*l.* to 70*l.* an acre, by the effects of the catchwater and navigable drains provided by the new scheme. Since this period nearly half a million of money has been spent in further improvements, in harmony with the plans of Telford and Rennie. In 1834, by making a new cut, removing an old sluice, and by some other works, the advantage of correct principles in draining was demonstrated in a remarkable manner. The works were finished on Saturday night, and on Sunday morning the water accumulated in far distant drains began to move. At Thorney, near Peterborough, fifteen miles from the sea, the people were at church when the cry was heard, "The waters are running!" when immediately "the whole flocked out, parson and all, to see this great sight, and to acknowledge the blessings of science."

ROAD-MAKING.

A FRENCH inventor has recently built, or at least designed, a steam roller to consolidate gravel and macadamised roads. A pair of cylinders, inclined at forty-five degrees, act on an outside crank on one end of the axle of the main roller or drum. The front axle has wheels as broad as can be, and is controlled by steering-gear similar to that used on steam-carriages and traction-engines. It is said that this machine will be better than horse-drawn rollers, because it can run both backwards and forwards with equal facility, be easily reversed and work on a short piece of road until it is sufficiently consolidated; and it does not impair its own work by digging it up, as horses' feet do. Without saying that this particular engine is the best that can be devised for this work, we confidently say that these claims are far within the limits of what is already demonstrated by engines built for other uses. We have ridden upon an engine that had a drum in place of a pair of driving-wheels, and have carefully observed its effects on a gravel road, and were convinced that such engines would make gravel roads as hard as the foot-path alongside of them—even much harder, because of their immense weight. But while horses beat up the roads, such material as gravel will be loose, unless rolled by great numbers of heavy rollers or broad wheels. Macadam, before a parliamentary committee, said that in dry weather the fast horses would make the roads too loose for quick travelling, were it not for the effect of the wheels in rolling down what the feet knocked up.

As the collection and distribution of all traffic must be by common roads, it is important to railways and all other main conveyances that common roads should be aided by the science that has thus far tended to deprive them of the attention necessary to keep them in economical condition. If more talent and money had been spent upon them less horseflesh, carriage-wear, and less time would have been lost upon them, and the result would have been a great saving of public wealth. Good rollers, especially if moved by a power that will not allow horses to disturb the surface until it is well hardened and levelled, may do much to mitigate the barbarism of common roads.

THE ORDNANCE ENQUIRY.

(From the *Liverpool Albion.*)

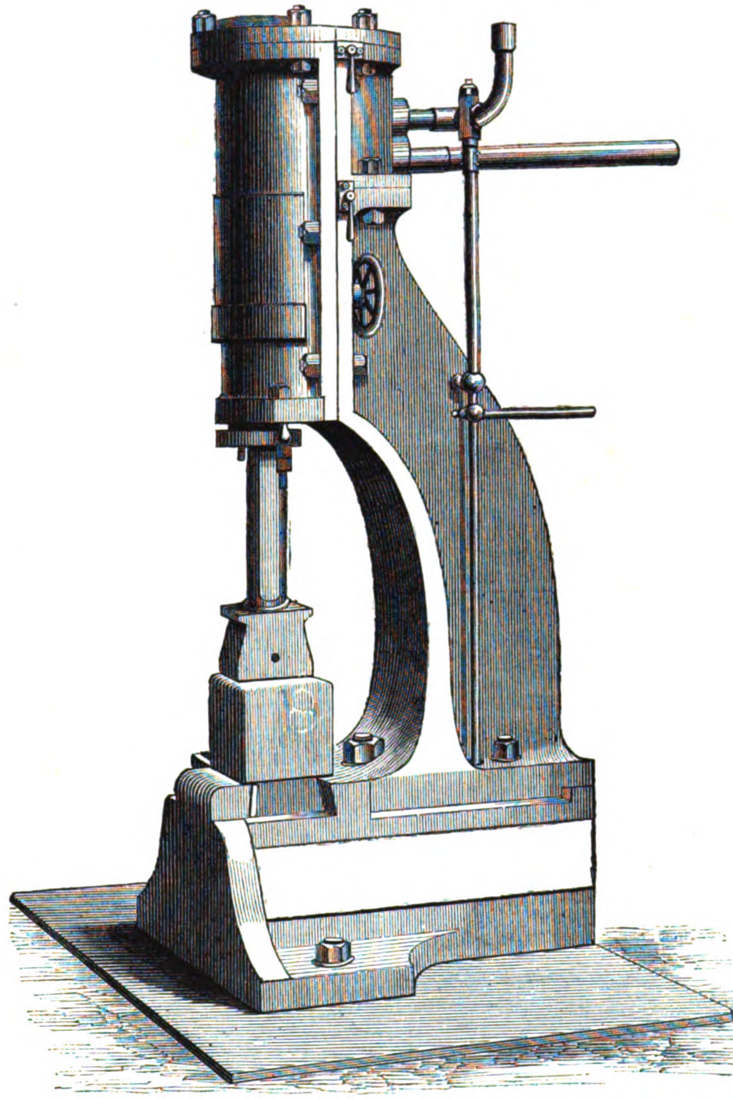
THE further the ordnance enquiry proceeds, and it has as yet scarcely advanced beyond the threshold, the more strongly the need of such an investigation, in the interest of the public, becomes apparent. The evidence given at the outset by Colonel Lefroy with respect to the circumstances under which the manufacture of Armstrong guns was conducted — the advance of 40,000*l.* by Government to the Elswick Company, the anomalous position of Sir William Armstrong, and the payment of prices averaging fifty per cent. above what the same articles can be produced for at Woolwich—was not a little startling to the public, and seems to have surprised those of the committee who are not participants in the secrets of the War Office. Major-General Tulloh has since given evidence which has brought to light many additional facts not at all calculated to mitigate the impressions produced by the evidence taken at the first sitting. It was important to ascertain what proportion of the guns made since the agreement was entered into with the Elswick Company have been constructed there, and what proportion at Woolwich, and also whether there was any actual want of means at Woolwich to produce the required supply of guns, without having recourse to private establishments at all, which would give a colourable excuse for the payment of prices to the Elswick Company, averaging 50 per cent., and amounting in some instances to more than 100 per cent., above the prices at which the same articles could be produced at Woolwich. Major-General Tulloh has been examined on this point, and his evidence makes the aspect of the transactions between the Government and Sir William Armstrong more suspicious than before. The Royal Gun Factory has never failed, he informed the committee, to supply all the guns that have been required, even during the war with Russia; and though many changes have been made from time to time in the construction of the Armstrong gun, which have interposed delays, the same thing took place in the case of the Lancaster gun, which, nevertheless, was produced at Woolwich to the extent required, without any very severe pressure upon the resources of the establishment. Why it should have required supplementing with the Elswick factory is, therefore, inexplicable by any of the considerations which would influence private individuals in dealing with their own affairs. Having the means of producing all the guns and projectiles which could possibly be required at Woolwich, why have the Government employed the Elswick Company so largely, and at prices so enormously above the cost of the same articles at their own factory? We learn, for instance, that orders have lately been given for twenty-four large smooth-bore guns, and that all but four of these are to be manufactured at Elswick. The reason assigned is, that the Elswick Company have a much larger steam-hammer than the largest at Woolwich; but why this has been allowed to be so, and why the means should have been given to the Elswick Company of setting up plant which should give them an advantage over the Government, we are not told. We learn, however, that the agreement between the Government and the Company obliges the former to profitably employ the plant set up by an advance of public money; and that in default the Company may demand compensation. We trust that this matter will be thoroughly sifted.

INTERNATIONAL EXHIBITION.

CLASS VIII., No. 1813.

THE illustration annexed represents one of Joy's patent steam hammers manufactured and exhibited by Messrs. Garrett, Marshall, and Co., of the Sun Foundry, Leeds. The principal advantage to be obtained from this hammer is its extreme simplicity, having no valve motion, levers, or stuffing box, nor any continuously moving part, except the "piston slide valve" and "hammer."

JOY'S PATENT STEAM HAMMER



The valve motion usually applied in self-acting hammers is more or less complicated, and gets out of adjustment and repair; this is here entirely superseded by allowing the steam which actuates the hammer to perform the office of valve motion, being admitted above and below the "piston slide valve" in the requisite quantity, and for a suitable period of time, to give any required stroke or quality of impulse to the hammer, without the disadvantage of too much "lead." This steam hammer is also double-acting, thereby giving the most powerful blow in the shortest space of time. The force of such blow can be regulated at pleasure with the greatest nicety, and the length of stroke can also be varied to whatever is requisite by merely adjusting the hand wheel shown above. In these hammers an increased bearance is given to the piston rod, &c., by the depth of the piston being more than its own diameter. For steel tilting and other work, when some 400 to 500 blows per minute are necessary, this hammer has its parts even further reduced to that of the piston rod and hammer head, only with additional length of cylinder and guidance.

A limited company, with a capital of 100,000*l.*, in shares of 50*l.* each, entitled the Hafod-y-Wern Slate Company, has been formed for further extending the quarry on the great Bangor slate range. Slates are at present being produced, and with the works which it is now proposed to carry out it is expected that the quarry will prove highly remunerative.

PRESERVATION OF MEATS.

AT a recent meeting of the Society for the Encouragement of National Industry, M. Peligot read the following note of M. Martin de Lignac on his new patented process for the preservation of meats:—

"In the usual way of salting, the meat is placed first in salt, and afterwards in the pickle. The salt absorbs the liquids in proportion as they separate from the flesh, then the pickle penetrates by endosmose, and preserves them from any subsequent alteration by its antiseptic properties. But in this case, the salt acts on the surface a long time before it penetrates to the centre, whence results an excess of salt at the surface, whilst the centre is not sufficiently salted, and still contains the principles of fermentation. To avoid this, the habit is to cut up the meat; but this, while it increases the chances of its preservation, greatly alters its quality. In fact, the salt in contact with large surfaces absorbs too largely the liquids contained in the flesh, and extracts from them the aroma and a portion of their nutritive juices. Pork, the tissue of which is dense and protected by fat, bears this preparation better than beef, the flesh of which, after long standing in the salt, presents only a fibrous tissue without flavour, and with but a low nutritive power.

"It results from these facts; first, that meat preserved by the usual process contains necessarily too much salt, and that its prolonged use is injurious to health; secondly, that it loses a part — sometimes a notable part—of its nutritive value.

"The method of avoiding these inconveniences is to salt uniformly and not subdivide too far the meat, thus preserving its aroma and its juices; I think that I have found the solution of this problem, and the following are the means which I employ:

"If it is a ham which I wish to salt, I introduce, by means of a trocar, between the bone and the muscle at the small end, a sound which I attach to a stop-cock which communicates by a tube with a reservoir of water saturated with salt, to which are added various aromatics and condiments. The reservoir is from 25 to 35 feet high. When the stop-cock is opened, the liquid by its pressure rapidly separates the muscle, and the two or three ounces of pickle which are necessary for the preparation of one pound of meat, are easily lodged in the cellular tissue which surrounds the bone. Thence it forms a kind of reservoir, the liquid spreads, penetrating all the fibres by infiltration, distributing regularly and homogeneously the conservative agent, and producing its first effect upon the part most susceptible of alteration, that which surrounds the bone. The hams thus prepared are put for some days in a pickle-bath. The object of this bath is to prevent by its pressure the issue of the liquid injected; besides which it completes the preparation by saturating the surface. When they leave the bath, the meat has lost nothing of the weight which it had at its entrance. I then expose them to a current of air at a moderate temperature. When by evaporation they have lost the infiltrated liquid and 5 per cent. of their normal weight, I expose them to the action of smoke for a time which varies with their weight. This latter operation is not necessary for their preservation, but it gives them a taste which is generally sought for, and effects a reduction of weight. On leaving the smoke-house they have lost from 12 to 15 per cent. of their weight; before entering they had already lost about 5 per cent., so that their whole loss is from 18 to 20 per cent." — *Cosmos.*

THE STRAIGHT LINE *VERSUS* THE WAVE LINE FOR VESSELS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—I cannot in courtesy decline replying to Mr. Moy; but I do hope we shall not drift into a trifling unprofitable manner of discussing the wave line theory, which we certainly shall if, instead of accepting the invitation I gave him, to defend that theory on its merits, or to dispute my refutation of it, he merely urges idle objections to my straight line system of moulding the bows of vessels. I allude to what he says of the evil of uniform motion, through "the inseparable jerks" which arise from sudden changes in matter "*from* a state of rest and *to* a state of rest." This is all quite correct in reference to the case by which he illustrates it—namely, the uniform motion that could be given, and which at one time many foolish inventors (under the teaching of equally foolish mathematicians, that the crank involved a loss of power) were bent on giving, to the piston of the steam-engine—because here the action is intermittent; but no shocks, no "jerks," can arise where both the action and the resistance are continuous and equably constant, as in the cleaving and eversion of water by the bows of vessels, whatever may be the suddenness and velocity with which it may be put into motion. This is so obvious, that I need not say another word, except incidentally to remark, that the gradual subsiding of the water into a state of rest, so far as the action of the bows is concerned, is common to both hollow and straight lines, if equally rounded off into the lines of the side of the vessel.

Mr. Moy treats the subject with his usual good sense when he refers to the results of experiments in proof of the superiority of the wave line. Now, unfortunately, experiments are as capable of leading us into the wrong path as mathematical theories; they equally require comprehensive thought, and also reasoning power apart from the trammels of narrow rigorous and literal deduction, to assign to them their proper interpretation in the one case, and their proper application in the other. Philosophers did not prove the existence of a principle of levity by pointing to the ascent of wood in water; neither did mathematicians convince practically-minded men of the power-losing character of the crank by a demonstration of the relative magnitudes and directions of components and resultants in the parallelograms of momenta and of pressures. And as to the case in hand, that portion of the resistance opposed to the progress of a vessel which is due to friction is relatively so large when the motion is slow, and the difficulties in other respects in the way of conducting experiments properly, especially with the needful velocities, are so great, that we may be easily led astray, and the more so if prepossessions occupy the mind. However, I, too, can refer to experiments, made by Mr. Bland with small models, and with low velocities, which seem to show, so far as they can be depended upon under such conditions, and others equally faulty, that the wave line is inferior to the straight line, and that a line slightly convex is superior to both. But reason tells me that the last conclusion cannot be correct, for where are we to arrive at the minimum of resistance in that direction? And this dictate of reason is confirmed by subsequent experiments, proving that a greater convexity is an evil. The fact is, the straight line was not rounded off into the side line, and the angle formed must have been injurious. Other causes connected with the comparative smoothness of the models might exist. They should have been varnished, and polished like glass.

But I can refer to practice, which is better still, in support of my side of the question. The ship Bremen, built by Messrs. Caird & Co., of Greenock, was reported on by the Committee of the British Association (of which I presume Mr. Atherton was reporter) as being a crack ship for doing work in proportion to engine power. Calculating by the formula $\frac{v^3 \times \text{Mid. Sec.}}{\text{I H P}}$ I make her coefficient to be 862. Now, the very highest number, as published, of the performances of Her Majesty's vessels is 724, the average being about 500. Well, this ship has slightly convex lines, of which some become hollow only upon a near approach to the stem, in order to avoid an angle, which is practically the same thing as straight lines rounded and hollowed at their extremities for the same purpose.

Mr. Moy is desirous of knowing "what angle of bow I prefer," and requests me to give "definite answers to definite questions;" but then his question should not be indefinite. He should define it with its circumstances and conditions. Lines for a frigate and for a yacht will not be equally appropriate. I am to *presume* that he alludes to the angle of the load-water section, although the angle of other horizontal sections are of equal, if not of greater, importance. So, being without definite particulars, I am unable to give him a definite answer. But, assuming that the load-water section is meant, that it is a case in which the finest bow consistent with advantage is desirable, and that it will be combined with yet finer lines below, I do not at present think the angle should be less than 10 degrees with the longitudinal axis; unless, indeed, the vessel should be of an enormous size, carrying ample breadth for stability, such as the Great Eastern, and in her, I believe, the angle is less than this. But the question would, or should, be very much influenced by the angles of other lines. All of which, as befalls all practical subjects, unless you have the particular case before you, is very indefinite, and very distressing to all mathematical and logical minds, adherents of the deductive order of reasoning, pure and exact.

Yours, &c.,

Benj. Cheverton.

July 14.

Shot-proof Ships.—It appears from a return to Parliament that the number of proposals and plans for the purpose of shot-proof ships submitted to the Admiralty between May 1, 1859, and May 1, 1862, amounts to 590. The whole were, in the first instance, referred to the Comptroller of the Navy and the assistant officers of his department for consideration and report; 85 were subsequently referred to the committee on iron plates; 19 to Captain Hewlett, commanding the gunnery ship at Portsmouth; and 1 to a special committee. On the 12th ult. there were 37 plans and proposals under consideration.

Gossip.

In the House of Commons, on Tuesday night, Mr. Laird asked the Secretary of State for War if he had decided when to try the Horsfall gun, and whether he had any objection that the trials be made at Shoeburyness upon the same target that was subjected to the Armstrong 300 pounder gun on Monday, the 7th inst., and also upon any other targets now making for experimental purposes.—Sir G. C. Lewis stated that arrangements had been made for the removal of the gun from Southsea to Shoeburyness, and for the trial of experiments with it against a target formed on the model of the sides of the Warrior.

The large dredger has come upon the wreck of a vessel in Shields Harbour, and the diver in the employ of the Tyne Commissioners is employed in lifting it by means of the weigh keel. This vessel is supposed to have lain in the bottom of the river since September 8, 1740. On that day the Prince Frederick, of Guernsey, was driven from her anchors in a great storm of wind, and ran foul of several vessels, some of which shared the same fate with her. The Prince Frederick, by the impetuosity of the wind on her larboard side, heeled gunwale in, and the starboard midship port being open to take in coals, the water filled her so quickly that she sank immediately. A Custom-house officer named Harbottle, two men, and a boy perished, two of them in the cabin. Several anchors of a much more ancient date have been fished up during the recent dredging operations in the Tyne; and some old armour, as if soldiers had been drowned while crossing the stormy waters of the Tyne, have also been brought to light.

On Saturday last a dinner of an unusually interesting character took place at Willis's Rooms, on the occasion of the anniversary of the Acclimatisation Society. The objects for which the society has been formed are the introduction, acclimatisation, and domestication of animals, birds, fishes, insects, and vegetables, whether useful or ornamental; the perfection, propagation, and hybridisation of races already domesticated; the spread of indigenous and naturalised animals, &c., from parts of the United Kingdom where they are already known to other localities where they are not known; the procuration, whether by purchase, gift, or exchange, of animals, &c., from British colonies and foreign countries; the transmission of animals from England to her colonies and foreign parts, in exchange for others sent from thence to the society; and the holding of periodical meetings, and the publication of reports and transactions for the purpose of spreading knowledge of acclimatisation, and of enquiry into the causes of failure. Lord Stanley occupied the chair.

Conversazione at the Royal Polytechnic.—The directors of the Polytechnic had a conversazione at the rooms of their Institution in Regent Street, on Wednesday evening, which was attended by a numerous assembly of ladies and gentlemen, comprising men eminent in science, patrons and friends of that popular Institution. If the affair was an experiment—and they are good at experiments there—the directors must have been as pleased at their success as their guests were gratified by the entertainment. There were a series of brilliant experiments with electricity, supplied by four powerful batteries, which were not only marvellous to the ordinary on-looker, but must have been surprising even to those who are well acquainted with the properties of that most subtle agent. Professor Wheatstone, who was present, must have been delighted by the result of investigations with which his labours have been so long connected. The hall was illuminated by four electric lights, one of which, in a cut-glass lantern, made for the occasion by Messrs. Defries, displayed every colour of prismatic ray with astonishing effect. The telegraph was busy transmitting messages to Paris, Vienna, and St. Petersburgh; Liverpool, Glasgow, and Dublin; to all of which answers were returned. Captain Bolton was present with his lime light, passing signals to Highgate Church, and Mr. Ward exhibited and explained the purposes of his ocean telegraph. There were also displayed many rare and curious articles from India; works of art in silver electro-plate and gold, from Messrs. Hunt and Roskell's; a variety of processes in manufacture, and scientific instruments of every variety. The evening was enlivened by music, vocal and instrumental, and when we add that abundance of refreshments was provided, it will be evident that the friends of the Polytechnic enjoyed a pleasant evening at that long honoured and successful school of the Arts and Sciences.

INTERNATIONAL EXHIBITION.

DISTRIBUTION OF AWARDS.

The ceremony of the distribution of the awards by the Commissioners of the International Exhibition took place on the 11th inst. The following is a list of the awards for mechanical contrivances, &c.:—

CLASS I.

MINING, QUARRYING, METALLURGY, AND MINERAL PRODUCTS.

JURORS.—Sir Roderick Murchison, F.R.S., F.G.S. chairman. Igino Cocchi, Italy; Chas. Combes, France; J. A. C. das Neves Cabral, Portugal; Lieut.-Gen. Alex. Gerngross, Russia; Sir W. Logan, Canada; Francisco Luxan, Spain; Sir Roderick Murchison, F.R.S., F.G.S., chairman, London; C. Overweg (Dr. Wedding, proxy), Zollverein; J. Percy, M.D., F.R.S., F.G.S., London; Warrington W. Smyth, M.A., F.R.S., F.G.S., secretary, London; Thomas Sopwith, F.R.S., F.G.S., Newcastle; K. Styffe, Sweden; Peter Tunner, Austria; A. de Vaux, deputy-chairman, Belgium; H. Hussey Vivian, M.P., F.G.S., Swansea; Nicholas Wood, F.G.S., Newcastle. Associates: Draubrée, France; Dubocq, France; J. Oakes, Alfreton.

MEDAL.—UNITED KINGDOM.—Aberdare Iron Co; Barker, Rawson, and Co; Bell Brothers; Bickford, Smith, and Co.; Birley, S.; Blaenavon Iron and Coal Co.; Bolckow and Vaughan; Bowling Iron Co.; Brown and Jeffcock; Brown, J., and Co.; Butterly and Co.; Cheesewring Granite Co.; Coal Owners of Northumberland and Durham; Courage, A., and Co.; Crawshay, H., and Co.; Daglish, J.; Dowlais Iron Co.; Eastwood and Sons; Ebbw Vale and Pontypool Co.; Evans and Askin; Farnley Iron Co.; Forster, G. B.; Freeman, W. and J; Geological Survey of the United Kingdom; Governor and Co. of Copper Miners; Gowans, J.; Granville, Earl; Greaves, J. W.; Greenwell, G. C.; Henderson, J.; Hewlett, A.; Higgs, S., and Sons; Hird, Dawson, and Hardy; Holland, S., and Co.; Holmes, J.; Howard, Hon. J.; Howard, Ravenhill, and Co.; Johnson, Matthey, and Co.; Kirkstall Forge Co.; Lilleshall Iron Co.; Lizard Serpentine Co.; Llangollen Slab and Slate Co.; Londonderry, Marchioness of; Lowry, J. W.; Macdonald, A.; Margam Tinplate Co.; Meik, T.; Mersey Steel Iron Co.; Michell, R.; Mona Mine Co.; Monk Bridge Iron Co.; More, Rev. T. F.; Museum of Practical Geology; Mylne, R.; Newcastle, Duke of; Parkside Mining Co.; Patent Plumbago Crucible Co.; Pearce, W., jun.; Pease, J. and J. H.; Price, Dr D. S.; Quilliam, T.; Rhiwbryfdir Slate Co.; Robinson, W., and Co.; Rogers, Ebr.; Salt—Chamber of Commerce; Schneider and Hannay; Scottish Ironmasters; Shelton Bar Iron Co.; Sim, W.; Smith, R., for Earl Dudley; Sunderland Local Committee; Swansea Local Committee; Taylor Brothers, and Co; Thompson, Hatton, and Co; Turner, Cassons, and Co.; Vint, G., and Brothers; Vigra and Clogau Copper Mining Co.; Weardale Iron Co.; Welsh Slate Co.; Wimshurst's Patent Metal Foil Co.; Wood and Daglish; Woodhouse and Jeffcock; Wombwell Main Coal Co.; Wright, S.; Ystalyfera Iron Co.

CANADA.—Billings, E., of the Geological Survey; English and Canadian Mining Co.; Foley and Co.; Hunt, J. Sterry, of Geological Survey; Larue and Co.; Montreal Mining Co.; Taylor, A.; the Officers of the Geological Survey of Canada; Walton, B.; West Canada Mining Co.; Williams, for Canadian Oil Co.

COLUMBIA.—Executive Committee.

INDIA.—Dr. Hunter; East India Iron Co.; Local Committee, Calcutta; Montgomery, Martin; Oldham, Professor; Rajah of Vizianagarum; Surveyor-General of India.

JAMAICA.—Lucas Barrett.

NATAL.—Sutherland, Dr.

NEW BRUNSWICK.—Commissioners of New Brunswick.

NEWFOUNDLAND.—Newfoundland Government.

NEW SOUTH WALES.—Australian Agricultural Co.; Dawson, A.; Keene, W.; Low, J. C.; M'Lean (Surveyor-General); Royal Mint.

NEW ZEALAND.—Bank of New Zealand; Heaphy, C.

NELSON.—Nelson Government.

OTAGO.—Holmes, M.

NOVA SCOTIA.—Honeyman, Rev.; Howe, Prof.; Provincial Government; Scott, J.

SOUTH AUSTRALIA.—Burra Burra Mining Co.; Kapunda Mining Co.; Wallaroo Mining Co.; Wheal Ellen Mining Co.

TASMANIA.—Calder, J. E.; Commissioners of Tasmania; Gould, C.; Milligan, J.

TRINIDAD.—Wall, G. P.

VICTORIA.—Bank of Australasia; Bank of New South Wales; Black Hill Mining Co.; Burkitt, A. H.; Clark and Sons; Clunes Mining Co; Colonial Bank of Australasia; Commissioners of Victoria Exhibition; Daintree, R.; Davidson, R.; Knight, J. G.; M'Coy, Prof. Fred.; Rowe, G.; Smyth, Brough; Selwyn, A.; Turner, W. J.; Victoria Government; Victoria Kaolin Co.

CLASS V.

RAILWAY PLANT, INCLUDING LOCOMOTIVE ENGINES AND CARRIAGES.

JURORS.—Duke of Sutherland, Chairman; W. Baker, C.E., London; G. P. Bidder, C. E. London; T. R. Crampton, London; Flachat, Deputy Chairman, France; James Kitson, Leeds; Krüger, Zollverein; J. E. Mc Connell, Wolverton; F. Spitaels, Belgium; Arch. Sturrock, Doncaster; Col. Jolland, R. E., F.R.S., Secretary, London.

MEDAL.—UNITED KINGDOM.—Ashbury, J.; Bateson, S. S.; Beattie, J.; Beyer, Peacock, and Co.; Brown, G. and J., and Co.; Fay, C.; Gibson, J.; Kitchin, R.; Manning, Wardle, and Co.; Mansell; Napier, Vickers, and Co.; Newell, J.; Pooley, H. and Son; Sharp, Stewart, and Co.; Wright, J., and Sons.

CANADA.—Larue and Co.

CLASS VI.

CARRIAGES NOT CONNECTED WITH RAIL OR TRAM ROADS.

JURORS.—General Morin, Director of the Conservatory of Arts and Manufactures, France, Chairman; Jos. Holland, London; H. Holmes, Derby; Geo. N. Hooper, Secretary, London; J. W. Peters, London; Viscount Torrington, Deputy Chairman, London. Associate: H. Tresca, France.

MEDAL.—UNITED KINGDOM.—Aldebert, J. Booker, and Sons; Braby, J., and Son; Briggs, G., and Co.; Cockshoot, J.; Cole, W.; Cook and Holdway; Edwards, Son, and Chamberlayne; Hall and Sons; Hazeldine, G.; Holroyd, Noble, and Collier; Hutton, J., and Sons; M'Naught and Smith; Mason, H. H.; Rigby and Robinson; Rock and Son; Shanks, R. H. and F.; Silk and Sons; Thrupp and Maberly; Turril, H. L.; Ward, J.; Woodall and Son; Wyburn and Co.

CLASS VII.

MANUFACTURING MACHINES AND TOOLS.

JURORS.—W. Fairbairn, F R.S, chairman.

SECTION A.—Boettcher, Zollverein; J. Callon (M. Luuyt, proxy), France; J. Cheetham, Staleybridge; M. Curtis, Manchester; Ben. Fothergill, London; J. Kindt, President of Section, Belgium; J. G. Marshall, Leeds.

SECTION B.—J. Anderson, Woolwich; Major Contl, Secretary, Italy; W. Fairbairn, F.R.S., Chairman and President of Section, Manchester; Robert Mallet, F.R.S., London; Rev. H. Moseley, M.A., F.R.S., Bristol; Dr. Rühlmann, Deputy Chairman, Zollverein; Baron Séguier, France; J. Whitworth, F.R.S., Manchester. Associates: Charles Buxton, M.P., London; William Gossage, Warrington; E. Pontifex, London.

SECTION A.—MACHINERY EMPLOYED IN SPINNING AND WEAVING, &C.

MEDAL.—UNITED KINGDOM.—Anderston Foundry Co.; Apperly, J. and Co.; Combe, J. and Co.; Dickenson, W. and Sons; Dobson and Barlow; Ferrabee, J. and Co.; Hattersley, G. and Son; Hetherington and Sons; Higgins, W. and Sons; Hodgson, G.; Mason, J.; Parker, C. and Sons; Platt, Brothers; Rowan, J. and Sons; Sharp, Stewart, and Co.; Smith, W. and Brothers; Tuer and Hall; Walker and Hacking; Wren and Hopkinson.

SECTION B.—MACHINES AND TOOLS EMPLOYED IN THE MANUFACTURE OF WOOD AND METAL.

MEDAL.—UNITED KINGDOM.—Barnett, S.; Bertram, G.; Beyer, Peacock, and Co.; Bradley and Craven; Clayton, H. and Co; De Bergue, C. and Co.; Donkin, B.; Fairbairn, P. and Co.; Forrester, G. and Co.; Garside, H.; Greenwood and Batley; Handyside, A. and Co.; Holtzapffel, L. and Co.; Hulse, J. S.; Johnson and Atkinson; Lockett, J., Sons, and Leake; Manlove, Alliott, and Co.; Mathieson, A. and Son; McOnie, W. and A; Mirrlees and Tait; Mitchell, W. H.; Morgan and Co.; Morrison, R. and Co.; Muir and Co.; Napier, D. and Sons; Normandy and Co.; Powis, J. and Co.; Robinson, T. and Son; Samuelson, M. and Co.; Siebe, D.; Siemens, Halske, and Co.; Sharp, Stewart, and Co.; Shepherd, Hill, and Co.; Smith, J. and Son; Smith, Beacock, and Tannett; Vicars, T. and T. and Co.; Waterlow and Sons; Naysmith and Co.; Worssam and Co.; Whitehead; Yates, W. S.; Youngman, C. T.

CLASS VIII.

MACHINERY IN GENERAL.

JURORS.—Michael Chevalier, Chairman—L. R. Bodmer, Switzerland; Chevalier de Burg, Austria; Earl of Caithness, London; J. Hawkshaw, F.R.S., F.G.S., London; J. Hick, C.E., Deputy Chairman, Bolton; J. M. da Ponte Horta, Portugal; C. Jenny, Austria; W. M. Neilson, C.E., Glasgow; John Penn, C.E., London; O. Pihl, Norway; Du Pré, Belgium; W. Macquorn Rankine, Secretary, Glasgow; F. B. Taylor, United States; H. Thomas, Zollverein. Associates: Carl Jenny, Austria; Paul Luuyt, France.

SPECIAL JURY OF CLASS VIII.—J. F. Bateman, F.R.S., London; Captain Bent, London; W. M. Brown, London; Earl of Caithness, London; J. Hawkshaw, London; C. Jenny, Austria; P. Luuyt, France; J. E. M'Connell, Wolverton; O. Pihl, Norway; W. M. Rankin, Glasgow; Captain Shaw, London; Duke of Sutherland, London; F. B. Taylor, United States; H. Thomas, Zollverein; H. Tresca, France.

MEDAL.—UNITED KINGDOM.—Allen, Harrison, and Co; Armstrong, Sir W. G. and Co; Ashton, J. P; Bastier, J. U.; Bowser and Cameron; Bray's Traction Engine Company; Broughton Copper Company; Carrett, Marshall, and Co; Chaplin and Co; Chedgey, J.; Clark, D. K., Clarke, E; Clayton, Shuttleworth and Co.; Eadie and Spencer; Easton, Amos, and Sons; Edwards, C. J. and Son; Fawcett, Preston, and Co.; Forrest and Barr; Fowke, Captain F., R.E.; Frieake and Gathercole; Greenwood, Batley and Co.; Gwynne and Co.; Harrison, J.; Harvey and Co.; Humphreys and Tennant; Imperial Iron Tube Company; Laird, J. Sons and Co.; Lambert, T. and Sons; Lilleshall Company; Lloyd, G.; Manchester Water Meter Company; Maudslay, Sons, and Field; McOnie, W. and A.; Merryweather and Son; Mirrlees and Tait; Middleton, T.; Morrison, R. and Co.; Napier, D. and Son; Napier, R. and Sons; Newton, Keates, and Co.; Normandy and Co.; North British Rubber Company; North Moor Foundry Company; Peel, Williams, and Peel; Preller, C. A.; Ransomes and Sims; Rennie, G. and Sons; Roberts, W.; Robinson, W.; Routledge and Ommanney; Russell, J. and Sons; Salter, G. and Co; Samuelson, M. and Co.; Shand and Mason; Siemens, C. W.; Stephenson Tube Company; Taylor, J. and Co.; Thomson, James; Thornewill and Warham; Tod and M'Gregor; Tuxford and Son; Webb and Son; Wenham, F. H.; Weston, T. A.; Whitmore and Sons; Wilson, J. C. and Co.; Williamson, Brothers.

VICTORIA.—Commissioners of Victorian Exhibition; Harper.

CLASS IX.

AGRICULTURAL AND HORTICULTURAL MACHINES AND IMPLEMENTS.

JURORS.—Marquis de Perales, President of the Cattle Club, Spain, Chairman.—C.E. Amos, C.E., London; Colonel Challoner, London; C. J. Dannfelt, Sweden; G. Devincenzi, Italy; E. Egan, Austria; Viscount Eversley, F.G.S., London; J. Gibson, Dalkeith; Professor B. S. Jorgensen, Denmark; Wellington Lee, United States; Lord Talbot de Malahide, F.R.G.S., Deputy Chairman, Dublin; Hervé Mangon, Joint Secretary, France; L. De Mathelin, Belgium; J. Miller, Falkirk; J. C. Morton, Joint Secretary, London; Sir Joseph Paxton, M.P., F.L.S., London; J. Pintus, Zollverein; Sir John Villiers Shelley, Bart., M.P., London. Associate: E. Moll, France.

MEDAL.—UNITED KINGDOM.—Aveling, J.; Bamlett, A. and Co.; Barrett, Exall, and Andrews; Bell, Rev. P.; Bentall, E. H.; Boby, R.; Bray's Traction Engine Company; Burgess and Key; Childs and Owen; Clayton, Shuttleworth, and Co.; Coleman and Sons; Cornes, J.; Croskill, W. (trustees of); Fowler, J. jun.; Garrett and Son; Green, T.; Hancock, J. and F. and Co.; Howard, J. and F.; Hereman, S.; Holmes and Sons; Hornsby and Sons; Hughes and Sons; Hunter, P.; Kemp, Murray, and Nicholson; Kennan and Sons; Musgrave, Bros.; Ormson, H.; Priest and Woolnough; Ransomes and Sims; Richmond and Chandler; Robey and Co.; Ruston, Proctor, and Co.; Sellar, G. and Sons; Shanks and Sons; Smith, W.; Smyth, J. and Sons; Snowdon, W.; Taylor, J. and Sons; Turner, E. R. and F.; Tuxford and Sons; Underhill, W. S.; Wallis and Haslam; Weeks, J. and Co.; Whitehead, J.; Whitmee, J. and Co.; Young, T. and T.

CANADA.—Gaskin, Captain P.; Jeffry, J.; M'Sherry, J.; Morley, J.; Paterson J.; Whiting and Co.

NEW BRUNSWICK.—New Brunswick Commissioners.

SOUTH AUSTRALIA.—Mellor, J.

VICTORIA.—Robinson and Co.

CLASS XI.

MILITARY ENGINEERING, ARMOUR AND ACCOUTREMENTS, ORDNANCE AND SMALL ARMS.

SECTIONS A AND B.—CLOTHING AND ACCOUTREMENTS, TENTS, CAMP EQUIPAGE, AND MILITARY ENGINEERING.

JURORS.—Sir J. Burgoyne, Bart., chairman.

SECTION A.—Major-General Sir Fred. Abbott, C.B., Secretary, London; Col. Jos. Hudson, London; E. Moisez, France; Viscount Ranelagh, London; Major Russell, Egypt; General Paolo Solaroli, Deputy Chairman, Italy.

SECTION B.—Baron Treuille de Beaulieu, France; General Sir J. Burgoyne, Bart., G.C.B., Chairman and President of Section, London; Captain Douglas Galton, R.E., F.R.S., London; Major-General Hon. Jas. Lindsay, M.P., London; Colonel Henry Owen, R.E., C.B., Plymouth.

SECTION C.—Sir W. Armstrong, F.R.S., C.B., London; Lieut.-General Giovanni Cavilli, Italy; General Guiod, France; General the Hon. A. Gordon, C.B., F.R.G.S., London; Major-General Hay, London; Colonel Messoud Bey, Turkey; L. Micheels, Belgium; Nich. Novitzky, Russia; Westley Richards, Birmingham; Colonel St. George, C.B., R.A., Woolwich; Lord Vernon, President of the Section, London; Weyersberg, Zollverein, Associate; Major Porter, R.E., London.

MEDAL.—UNITED KINGDOM.—Adair, Colonel; Department of the Inspector-General of Fortifications and the Royal Engineer Establishment at Chatham; Ducane, Captain E. F.; Fowke, Captain R. E.; James, Colonel Sir H.; Jones, Serjeant-Major; Lovell, J. W.; Royal Medical Department of the War Office; Topographical Department of the War Office; Turner, G.

SECTION C.—ARMS AND ORDNANCE.

MEDAL.—UNITED KINGDOM.—Adams, R.; Baker, F. T.; Birmingham Military Arms Trade; Blakely, Captain; Bland, Captain; Brazier, J.; Chevalier; Daw, G. H.; Dougall, J. D.; Ebrall, S.; Elswick Ordnance Company; Fox, Lieut.-Colonel A. Lane; Gibbs, G.; Gladstone, H. and Co.; Gisborne, F. N.; Grainger, J.; Lancaster, C. W.; Lang, J.; London Armoury Company; Manton, John and Sons; Mont-Storm, Wm.; Royal Carriage Department, Woolwich; Royal Gun Factories, Woolwich; Royal Laboratory, Woolwich; Royal Small Arms Factory, Enfield; Sharpe, B.; Whitworth Rifle and Ordnance Company; Wilkinson and Son.

CLASS XII.

NAVAL ARCHITECTURE, INCLUDING SHIPS' TACKLES.

JURORS.—Robert Napier, shipbuilder, Glasgow, chairman.

SECTION A.—Rear-Admiral Fitzroy, F.R.S., London; Rear-Admiral P. Lisiansky, Russia; Paris, Deputy Chairman, France; J. D'A. Samuda, London; Isaac Watts, C.B., London. Associates: R. Abethell, London; Captain Belavenetz, Russia.

SECTION B.—Right Hon. Milner Gibson, M.P., London; Sir W. Snow Harris, F.R.S., Plymouth; Mangin, France; Rear-Admiral Washington, F.R.S., President of Section, London.

SECTION C.—Clapeyron, France; H. D. Cunningham, F.R.G.S., Portsmouth: W. S. Lindsay, M.P., London; Rear-Admiral R. S. Robinson, London. Associate: Evans, R.N., London.

SECTION A.—SHIPS FOR PURPOSES OF WAR OR COMMERCE.

MEDAL.—UNITED KINGDOM.—Admiralty Modeller; Coles, Cowper, Captain, R.N.; Denny Brothers, W; Gray, J. W. and Son; Griffiths, R.; Hornsey, W.; J. Jones, jun, Kirkaldy; Laird, J. Son and Co.; Lords of the Admiralty; Mare, Messrs. J. C. and Co.; Rennie, G. and Son; Russell, J. S.; Thames Iron Works and Ship Building Co.; Thompson, N.

SECTIONS B AND C.—LIFE BOATS, BARGES, AND VESSELS FOR AMUSEMENT, AND SHIP'S TACKLE AND RIGGING.

MEDAL.—UNITED KINGDOM.—Brown, Lenox and Co.; Clifford, C.; Dent and Co; Halkett, P. A.; Herbert, G.; Lords of the Admiralty; Lords Commissioners of the Admiralty; Martin, C.; Parkes, H. P.; Peacock, G.; Royal National Life Boat Institution; Searle, E.; Sinibaldi, Madame; Trotman, J.; Ward, Captain T., R.N.; West, J. G. and Co.; Wood, Brothers, and Co.

NEW SOUTH WALES.—Reynolds, A.

NEW ZEALAND.—Lloyd, Neil.

NOVA SCOTIA.—Mesher, J.

TASMANIA.—Commissioners for Tasmania.

CLASS XV.

HOROLOGICAL INSTRUMENTS.

JURORS.—Viscount de Villa Maior, Portugal, Chairman: Dr. Frick, Zollverein; Ch. Frodsham, Secretary, London; Rt. Haswell, London; E. D. Johnson, London; Laugier, Deputy Chairman, France; Sylvain Mairet, Switzerland; Rear-Admiral Manners, F.R.A.S., London; Lord Wrottesley, F.R.S. London.

MEDAL.—UNITED KINGDOM.—Adams and Son; Barraud and Lund; Bennett, J.; Blackie, G.; Brooks, S. A.; Cole, J. F.; Condliff, J.; Cooke, T. and Sons; Delolme, H.; Dent and Co.; Dent, M. F. and Co.; Ganeval and Callard; Guib et and Rambal; Guillaume, E. and C.; Hewett, S. and J. Prescott Committee; Hutton, J.; Jackson, W. H. and S.; Klaftenberger, C. J.; Kullberg, V.; Losada, J. R.; M'Lennan; Molyneux, W., Prescott Committee; Moore, B. and J.; Nicole and Capt; Parkinson and Frodsham; Pendleton, P., Prescot Committee; Poole, J.; Rotherham and Sons; Saggerson, E., Prescott Committee; Sewill, J.; Smith and Sons; Walker, J.; Walsh, A. P.; Webster, R.; White, E.; Wycherley, J., Prescott Committee.

CLASS XXXI.

Hardware.

Jurors.—Dr. Von Steinbeis, Stuttgart, Chairman.

Section A.—J. G. Appold, F.R.S., London; W. Bird, London; Giulio Curioni, Italy; Daubrée, France; Chev. de Fridau, Austria; A. Grill, Sweden; H. E. Hoole, President of Section, Sheffield; J. Oakes, Alfreton; D. S. Price, Ph. D., F.C.S, Secretary, London; L. Ravené, jun., Zollverein; G. Shaw, Birmingham; L. Trasenter, Belgium. Associates: M. J. Harpley, London; C. Lan, France; A. Upward, London.

Section B.—S. Buckley, Birmingham; E. Gem, Birmingham; P. C. Hardwick, President of Section, London; V. Paillard, France; Ferdinand Stamm, Ph. D., Secretary, Austria; Dr. Von Steinbeis. Chairman, Zollverein; A. Tylor, Deputy Chairman, London.

Section C.—Robert Fletcher, Birmingham; Goldenberg, France; W. A. Rose, London; G. Stobwasser, President of Section, Zollverein; J. S. Wyon, Secretary, London.

Section A.—Manufactures in Iron.

MEDAL.—United Kingdom.—Avery, W. and T.; Baily, W. and Son; Barnard, Bishop, and Barnards; Barton, J.; Benham and Sons; Bennett, T.; Bennett W.; Billinge, J.; Binks, Brothers; Bolton, T. and Sons; Bradford, T.; Bramah and Co.; Brown and Green; Brown, Lenox, and Co.; Buist, G.; Bullock, T. and Son; Butler, J. and Sons; Carron Iron Company; Chubb and Son; Clark, T., C., and Co.; Coalbrookdale and Co.; Cornforth, J.; Cottam and Co.; Cotterill, E.; Day and Millward; Deane, E.; Dollar, T. A.; Duley and Sons; Edelsten and Williams; Edwards, F. and Son; Evans, J. and Co.; Feetham. M. and Co.; Field, W. and Son; Finlay, J.; Firman and Sons; Flavel, S. and Co.; General Iron Foundry Company; Glass, Elliott, and Co.; Greening, N. and Sons; Griffiths and Browett; Hammond, Turner, and Sons; Handyside, A. and Co.; Hargreaves, W.; Hawkins, J. and Co.; Heaton, R. and Sons; Hewens, R.; Hiatt and Co.; Hobbs, Ashley, and Co.; Hopkins, J. H. and Sons; Iles, C.; James and Sons; Jeakes, C. and Co.; Jenkins, Hill, and Jenkins; Jones and Rowe; Keith, G.; Kennard, R. W. and Co.; Kenrick, A. and Sons; Kent, G.; Knight, Merry, and Co.; Leoni, S.; Linley, T. and Sons; Mander, Weaver, and Co.; Martineau, F. E. and Co.; Maxwell, H. and Co.; Nettlefold and Chamberlain; Onions, J. C.; Patent Enamel Co.; Peyton and Peyton; Pierce, W.; Potter, T.; Price, C. and Co.; Price, G.; Radclyffe, T.; Reynolds, J.; Rollason, A. and Sons; Scott, J. W.; Siebe, D.; Exhibitor, Harrison, Smith, F. and Co.; Stickley, C.; Stuart and Smith; Summerscales, W. and Son; Tann, J.; Titford, R. V. and Co; Tucker and Reeves; Tylor and Pace; Warden, J. and Sons; Watkins and Keene; Watkin, W. and Co.; Webster and Horsfall; Wenham Lake Ice Company; Whitfield, T. and Co.; Williamson, W.; Wilkins and Weatherly; Winfield, R. W. and Son; Wright, P.; Yates, Heywood, and Drabble.

Victoria.—Hughes and Harvey.

Section B.—Manufactures in Brass and Copper.

MEDAL, United Kingdom.—Benhams and Froud; Bischoff, Brown, and Co.; Croll, Rait, and Co.; Duckham, H. A. F.; Glover, G., and Co.; Glover, T.; Guest and Chrimes; Hardman, J. and Co.; Hart and Son; Hinckes, J., and Son; Lambart, T., and Son; Leale, A.; Messenger and Sons; Newton, Keats, and Co., Philip, C. J.; Prosser, W., and H. J. Standly; Skidmore, Art-Manufacturers' Co.; Strode, W.; Sugg, W.; Thomason, J., and Co.; Tonks, W. and Sons; Warfield; Warner and Sons.

Section C.—Manufactures in Tin, Lead, Zinc, Pewter, and General Braziery.

MEDAL.—United Kingdom.—Chatterton, J.; Dixon, J., and Sons; Gilbert, J. A., and Co.; Loveridge, H., and Co.; Wilson, R. and W.

CLASS XXXII.

Steel.

Jurors.—Lord Wharncliffe, Chairman.

Section A.—J. Brown, President of Section, Sheffield; Fremy, Deputy Chairman, France; Robert Jackson, Secretary, Sheffield; Thomas Jessop, Sheffield; Dr. Karmarsch, Zollverein.

Section B.—Henry Atkin, London; De Hennezel, France; M. Hunter, jun., Secretary, Sheffield; William Matthews, Sheffield; Basil Roshkof, Russia; Baron Sobrero, Italy; F. Wertheim, President of Section, Austria.

Section A.—Steel Manufactures.

MEDAL.—United Kingdom.—Bessemer, H.; Boulton and Son; Cammell, and Co.; Gillott, J.; Goodman, G.; Hinks, Wells, and Co: Kirby, Beard, and Co.; Knights and Co.; Milward and Sons; Mitchell, W. (Birmingham); Mogg, and Co.; Myers and Son; Naylor, Vickers, and Co.; Page, W. and J.; Perry, J., and Co.; Shortridge, Howell, and Co.; Smith and Houghton; Thomas and Sons; Townsend and Co.; Turner, M., and Co.; Turton Brothers.

Section B.—Cutlery and Edge Tools.

MEDAL.—United Kingdom.—Addis, J. B.; Allarton and Powell; Baker, W.; Brookes and Crookes; Eadon and Sons; Eastwood, G; Fuller, J. H.; Gibbins and Sons; Gilpin, W., sen. and Co.; Greenslade, E. A. and W.; Hannah, A.; Hardy, T.; Hawcroft and Sons; Howarth, J.; Jowitt and Son; Linneker, R. and J.; Mappin, Brothers; Mappin and Co.; Marsh, Brothers and Co; Mechi and Basin; Parkin, J.; Peace, Ward, and Co.; Rodgers and Sons; Saynor and Cooke; Steer and Webster; Taylor, H.; Unwin and Rogers; Waldrow and Sons; Wilkinson, W. and Son; Wilkinson, T. and Son; Wostenholm and Son.

Canada.—Gaskin, Capt. R.; Tongue and Co.

Note.—In the preceding List of Awards it frequently happens that the same exhibitor has been voted awards by more than one jury. These duplicate awards have been allowed to remain on the record; but according to the decision of Her Majesty's Commissioners, and of the Council of Chairmen, only one medal will be given to an exhibitor, unless the objects rewarded are exhibited in distinct classes.

LYON PLAYFAIR,
Special Commissioner for Juries.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

Steam Engines, 16.
Boilers and Furnaces, *None.*
Roads and Vehicles, 3261, 1, 10, 12.
Ships and Boats, 3263, 9.
Cultivation of the Soil, 3265, 15.
Food and Beverages, 3257, 13.
Fibrous Fabrics, 3258, 3260, 3276, 7, 20.
Buildings and Building Materials, 11.
Lighting, Heating, and Ventilating, 3259, 3264, 3267, 6, 14, 17.
Furniture and Apparel, 3262, 3266, 3269, 3274, 2, 8.
Chemistry and Photography, *None.*
Warfare, 5.
Miscellaneous, 3268, 3270, 3271, 3272, 3273, 3275, 3, 4.

3257. W. E. Newton. *Improvements in the manufacture of cube sugar.* (A communication.) Dated Dec. 30, 1861.

This consists, 1, in exposing the grains or crystals to the action of steam, by which the surfaces are subjected to the necessary degrees of heat and moisture, to give them the requisite degree of adhesiveness to form the cubes. 2. In the formation of the cubes by means of machinery composed principally of an endless or continuous series of moulds fitted with compressing and discharging pistons, and having applied in combination with them a cam or cams or their equivalents for operating the pistons one or more at a time in regular succession throughout the whole series, so that if the moulders are regularly supplied with granular sugar, a continuous delivery of compactly-compressed cubes will be effected. *Patent completed.*

3258. J. B. Payne. *Improved machinery for the manufacture of laid and other twine, lines, ropes, bands, and other cordage, whether made of hemp, flax, or other fibrous substances, or of wire.* Dated Dec. 30, 1861.

This invention is not described apart from the drawings. *Patent completed.*

3259. A. I. Austen. *Improvements in the manufacture of night lights.* Dated Dec. 30, 1861.

This invention consists in producing transparency in the case, and a polish on the outside of the ordinary thick box or "round" used in the manufacture of night-lights, by saturating the box with a candle or night-light material of a higher melting point than the fatty material which the box surrounds. The method most suitable in producing this transparency and polish is to steep the box in a preparation of stearine and wax, which, when withdrawn, is allowed to drain in a hot closet; the boxes are then placed on a mandril, and while revolving in a lathe or otherwise a polish is produced by the friction of a flannel or other suitable pad. *Patent abandoned.*

3260. W. Tongue. *Improvements in the manufacture of certain descriptions of woven looped and bobbin net fabrics, by the application of certain fibrous materials thereto* Dated Dec. 31, 1861.

The first and second parts of this invention consist in the application to the manufacture of woven, looped, and bobbin net fabrics of fibres obtained from certain plants growing in Assam and other parts of Eastern Asia, and in all parts of the East Indian peninsula. The second part of the invention consists in crossing the warp thread in the manner known as cross weaving, when manufacturing woven fabrics known as "gauzes," in the manner and from the materials described in the second part of the invention. *Patent completed.*

3261. A. Macnair. *Improvements in axle boxes for railway carriages.* (A communication.) Dated Dec. 31, 1861.

Here the journal of the axle is formed and shaped in the ordinary manner, but instead of the usual bearing made of brass or other metal, a strong hoop of iron, steel, or other suitable metal is made; this hoop is turned or bored in the inside, so that the journal exactly fits into the shape in which the hoop is bored. This hoop is four or five times in its inside diameter greater than the external diameter of the journal; or it may be of other proportions. The hoop is carried by and connected to the inside of the axle box by a metal wheel of suitable size, also turned on its outside to the same shape and length as the shape and length of the journal, and this metal wheel revolves freely on a pin of steel, or other metal of suitable strength, securely fixed in the axle box. The axle box slides freely in the horn-plates, by the grooves formed on it outside. The journal is kept steady in the axle box by guides formed on the inside end of the box, which act as guides to the axle. *Patent abandoned.*

3262. W. Lougue. *Improvements in the manufacture of umbrellas and parasols.* Dated Dec. 31, 1861.

This consists in weaving the fabrics for covering umbrellas and parasols from "China grass" and "Rhea fibre," also from the fibre known as the "mudar" or "yercum fibre." *Patent completed.*

3263. T. and W. Green, and R. Mathers. *Improvements in chains for giving motion to chain-wheels, and in giving motion to machinery.* Dated Dec. 31, 1861.

This consists, 1, in constructing chains used for giving motion to chain-wheels with extra links, or what may be termed guard links on each side of the driving-links; these extra links are to overlap the edges of the teeth of the chain wheels, and they serve to keep the chain in its place on the wheels. When using these chains, flanges are not required in the chain wheels. 2. In giving motion to machinery by the combined use of a chain and chain wheels, and friction surfaces, such as a pulley and band or friction wheels, which wheels may be plain grooved. *Patent completed.*

3264. N. McHaffie. *Improvements in ventilators or valves for regulating the passage of air or other fluids, whether of a gaseous or liquid form.* Dated Dec. 31, 1861.

Here, when applying a ventilator or valve for admission of external air, the patentee causes the current of air to impinge on a surface so arranged that, when the current of air exceeds the velocity considered desirable, the surface may be able to yield to it, and on yielding may close or partially close the valve. When the force of the current diminishes, the valve again opens, it being so weighted as always to tend to do so. For the passage of liquids, this last-mentioned surface should be mounted on a horizontal axis, but instead of being at or near its lower extremity, it should be at or near its upper extremity, on account of the greater density of the fluid, the passage of which is sought to be regulated. *Patent completed.*

3265. T. Pickford. *Improvements in the manufacture of manure.* Dated Dec. 31, 1861.

In preparing manure according to this invention, the inventor azotizes, ammoniates, and manipulates Sombrero Island phosphate guano according to a new process, in order to produce valuable manure equal in all and superior in some qualities to the Peruvian guano. He effects this object by mixing in pans, tanks, or chests (or chests either lined with lead or not), the Sombrero Island phosphate guano and other animal or bone phosphates in certain proportions, small sea shells ground to a fine powder (cockle shells preferred). He then adds to about one ton of the above mixture about one cwt. of Peruvian guano, saturated with urine, diluted sulphuric acid, and muriate of sodium in a mixer, and adds certain proportions of magnesian limestone (say about 100 lbs.) powdered and mixed with bones or gas sulphates of ammonia. *Patent abandoned.*

3266. F. Tolhausen. *A new method and machinery for covering springs used for petticoats and other articles.* (A communication.) Dated Dec. 31, 1861.

This consists in coiling the thread round the spring at a greater or less angle of inclination; further, in dressing the said thread before or after coiling with the proper agglutinative, or gelatinous matter, such as gelatine or size, or dressing the spring previous to being coiled, so as to cause the coils to stick together and form one solid body like a woven fabric; and, lastly, in passing the springs or ribs so coiled through a set of embossed rollers, by which the cohesion of the coil is further improved upon, and the proper gloss and fabric-like appearance is given. *Patent abandoned.*

3267. W. Spence. *Improvements in deflectors for lamps.* (A communication.) Dated Dec. 31, 1861.

The object here is the prevention of the partial obscuration of light from the lamp, caused by surrounding the flame with a deflector composed of an opaque material, and consists in the substitution of a deflector composed of glass or other transparent material for that which is ordinarily composed of metal. The deflector is in form similar to those in ordinary use as applied to lamps in which kerosene and other heavy oils are burned, such form being that of a hollow cone with a hole at the top of the form required to suit the form of the wick. *Patent completed.*

3268. J. Haslem. *Improved apparatus for winding, holding, and letting go cords, bands, or chains.* Dated Dec. 31, 1861.

The first part of this invention refers to the formation of blind-rollers where the ordinary endless cord is used, and consists, first, in making the roller and pulley of one solid piece of wood; secondly, in making the pulley if separate of gutta percha, India-rubber, leather, baffalo hide, or horn; thirdly, in a substitute for the rack and pulley used to distend the endless cord. The second part of the invention refers to that class of blind furniture wherein a single cord is employed coiled on a barrel at one end of the roller, and consists, first, in making the barrel either of one piece of solid wood with the roller, or, if separate, of any of the substances above-mentioned; secondly, in an improved apparatus for holding and releasing the cord as required. *Patent completed.*

3269. W. H. Bailey. *Certain improvements in sewing machines.* Dated Dec. 31, 1861.

This invention is not described apart from the drawings. *Patent completed.*

3270 W. E. Newton. *Improved apparatus for obtaining motive power from explosive compounds.* (A communication.) Dated Dec. 31, 1861.

Here a cylinder is employed provided with two pistons, the rods of which pass through stuffing boxes or guides in the ends of the cylinder. An arrangement of valves is adapted to the middle part of the cylinder to admit the gases into the cylinder. The expansion of the gases when exploded will drive the pistons forward, and as the rods of the latter are connected to the lower ends of a pair of vibrating levers, which are suspended from suitable bearings, these levers are caused to vibrate on their centres, and by means of connecting rods they communicate rotary motion to a crank shaft. A fly-wheel and driving pulley are mounted on this crank-shaft, and, of course, rotate with it, and may be used for giving motion to any machinery. *Patent completed.*

3271. W. E. Newton. *Improved apparatus for boring rocks and other mineral substances.* (A communication.) Dated Dec. 31, 1861.

This invention is not described apart from the drawings. *Patent completed.*

3272 E. Liphaugne and D. Delbosque. *An improvement in advertisements.* Dated Dec. 31. 1861.

Provisional protection has not been granted for this invention.

3273. J. B. Cretal. *A new process of colouring smoking pipes.* Dated Dec. 31, 1861.

The inventor dips the pipes in a solution of alcohol, cashoo, and aloes, and he then puts them in an oven that can be heated to 300° centigrade. To colour the top of the pipe, or rather of its bowl, he dips it in a solution of milk and caramel (burnt sugar). The so-coloured pipes he varnishes with some carabee, and exposes them in an oven to a heat of 200° centigrade, or thereabout. *Patent abandoned.*

3274. E. T. Hughes. *Improvements in saddles.* (A communication.) Dated Dec. 31, 1861.

This consists in an arrangement of stops placed in an angular position upon the side of the saddle, so as to gather over the leg of the rider, and aid him in keeping down upon

his seat in resistance to either a sudden lateral movement of the horse, or to an abrupt check in his career; and also permit a very available support for the holsters of a military saddle, and to secure them certainty of position. *Patent completed.*

3275. R. A. BROOMAN. *Improvements in revivifying animal black or charcoal, in collecting ammoniacal gases generated in the revivification, in the clarification of saccharine liquors, and in apparatus employed in the revivification of the black, and in the filtering of saccharine liquors.* (A communication.) Dated Dec. 31, 1861.

This consists in revivifying animal black, or charcoal, by wet processes, hot water or steam, acting in the filtering vessels, whether for renewing its powers for absorbing lime, or for renewing its properties for absorbing azoted, ammoniacal, and colouring matters; secondly, in revivifying animal black by acids, to eliminate lime from defecated saccharine liquors; thirdly, in the clarification of saccharine liquors, juices, and syrups, by means of phosphates; fourthly, in certain different methods of revivification of animal black, which allow of the collection of the ammonia given off in the revivification; fifthly, in apparatus (which is not described apart from the drawings) for carrying parts of the invention into effect. *Patent completed.*

3276. A. and J. EDWARD. *Improvements in machinery or apparatus for spinning fibrous materials.* Dated Dec. 31, 1861.

The framing of this machine consists of the ordinary end standards or gables connected to longitudinal rails. The spindles are longer than those in ordinary use; they are carried in footstep and collar bearings in two stationary parallel rails in the usual way. The upper parts of the spindles pass through the movable rail or lifter, which is carried on sliding rods that are caused to descend as the yarn is wound on to the pirn. The spindles are driven in the usual way. At the part where each spindle passes through the lifter there is fitted in the movable rail a neck-brass or additional collar-bearing, which is screwed into the lifter, and on this neck-brass or collar-bearing the pirn rests. Behind the spindles, and in a plane above the lifter, is arranged a longitudinal rail, which rests on slide brackets. These brackets have at the lower part of each a rack, which is actuated by a pinion arranged opposite thereto on a horizontal shaft, which is driven from the upper gearing of the machine. The movable longitudinal rail has a pair of brackets bolted to its upper face, which carry a horizontal shaft, having fitted to it a pair of heart wheels. The peripheries of these wheels bear upon pulleys carried on the backward ends of two levers, which are centred on a bracket piece fixed to the traversing rail. This lever is connected by a link to a lifter, so that the motion of the heart-wheel gives a short vertical traverse thereto, and in this way builds up the cone of the pirn. *Patent completed.*

---

1. J. M. ROWAN. *Improvements in the manufacture of railway wheels and in apparatus to be used therein.* Dated Jan. 1, 1862.

This has reference to a previous patent dated November 28, 1861 (No. 3,000), and consists in forming a dove-tail groove on each side of the rim of the spoke frame, the groove on one side fitting a dove-tail rim projecting inwardly from the outer edge face of the tyre, whilst a dove-tail groove is formed round the inside cylindrical face of the tyre near the inner edge face, and in this groove there is inserted a series of segmental keys, which are formed with duplex dove-tails, so as to be held firmly in the tyre groove, and to clip and hold the spoke rim by locking in the dove-tail groove formed upon it. To admit the segmental keys, the part of the tyre forming the outer side of the groove is cut away at intervals, and the keys are introduced at the cut away parts, and forced round under the uncut parts. *Patent abandoned.*

2. N. C. SZERELMEY. *Improvements in the manufacture of leather cloth or imitation leather, and in rendering certain fabrics waterproof.* Dated Jan. 1, 1862.

The patentee claims the use of the substance called zopissa in the manufacture of leather cloth, or imitation leather, and in rendering linen, woollen, and other fabrics waterproof. Also a mode of making leather cloth or imitation leather. *Patent completed.*

3. J. H. JOHNSON. *Improvements in hose pipe joints or couplings.* (A communication.) Dated Jan. 1, 1862.

Here according to one modification, it is proposed to use two metal cylinders or collars fitted respectively in any convenient manner to the ends of the hose pipes to be coupled. One of these cylinders or collars is made to fit easily inside the other, and has a beveled groove made round it, a short distance from its main extremity or end face, which face bears against a packing ring, or washer of any suitable material, inserted inside the larger or outer cylinder. An inner projection or flange, which is beveled to correspond to the level of the groove in the inner cylinder, is formed on the inner surface of the outer cylinder, and fits into the groove above stated. On the diametrically opposite side of the outer cylinder to that in which the internal projection is situate, there is a wedge, or screw plug passing through the cylinder, and through a collar thereon, and provided at its outer end with a suitable head for turning the screw, whilst the inner end of the pin or plug is tapered or beveled to fit the groove in the inner cylinder before referred to. In coupling the parts, the screw pin or plug is partially withdrawn, so as to allow the inner cylinder to enter the outer one freely, and pass its end over the internal beveled projection, so as to cause such projection to fit into the beveled groove; the screw plug is now caused to enter the groove on the opposite side by turning it either by hand or a spanner, the effect being to lock the two parts effectually together. *Patent completed.*

4. T. HALL. *Removing weeds from canals, rivers and lakes after such weeds have been cut with a chain scythe or other machine, or implement applicable to that purpose, which invention I intend to designate and call a "weed dredging machine."* Dated Jan. 1, 1862.

The extreme length of the specification of this invention precludes our quoting it here at sufficient length for an intelligible abstract. *Patent abandoned.*

5. J. WALKER. *Improvements in the construction of forts and fortifications which are applicable to floating batteries.* Dated Jan. 1, 1862.

The patentee claims, 1, constructing floating vessels, or batteries, or structures, so that they may contain one or more forts or gun towers revolving in or by water, and rising or falling in or by water, in a tank or other suitable structure formed in or by such vessel or structure. 2, armour-plates forged, rolled or planed, formed, and fitted, as described, and of all dimensions. 3, solid flanged or flanged and webbed prongs, forged, rolled or planed, and cut in the form described, with square and keyed, or with round and screwed ends, and of all dimensions. 4, moving the head or stern of a ship or vessel 'short round,' by a force pump or other power, for the purpose specified, and for steering. 5, the mode of forming timber and sheathing the hulls, decks, and roofs of vessels as described. And, lastly, the bridge-shaped ribs for vessels. *Patent completed.*

6. T. C. CLARKE. *Improvements in the construction of apparatus for heating and circulating water and other liquids.* Dated Jan. 1, 1862.

This relates to the construction of the bottom or the fore part of those apparatuses usually built in brick work, and known as cast boilers, such boilers being mostly used for heating and circulating water or oil through pipes or tubes for warming green-houses and other buildings. To obtain a large heating surface and economy of fuel, the patentee casts the said apparatus of a cylindrical form, with a water jacket around the same, and with hollow fire bars across the bottom, so that at the back of almost every part where the heat impinges there is a water space, and as all the water spaces communicate with each other, a circulation is maintained, as is well known. In the side of the cylindrical casing before named, there is an opening in the brick-work through which to supply fuel. Near the bottom there are water supply or return pipes, and near the top are the exit or hot water discharge pipes, which may be connected to another boiler placed above the one just described, so that the water may be further raised in temperature before discharged into the circulating pipes, and the waste heat economised. To prevent waste of fuel there is a cover or flue plate placed on the top of the boiler to prevent the heat escaping too rapidly, which may be regulated by the dampers. *Patent completed.*

7. JOHN BRADBURY. *Improvements in self-acting mules.* Dated Jan. 1, 1862.

This relates to improved modes of turning the cam shaft, and has for its object the prevention of breakages, and causing certainty of action. Instead of the ordinary friction pulley having four grooved cavities, and the escape lever and parts connected with it, the inventor uses, at the end of the cam shaft, a boss or plate having four teeth or projections, acted upon one after the other by a rod having at the end a small pulley. The said rod is moved upwards or forwards, at the required time, by four pins upon a revolving plate or pin wheel, put in motion by gearing communicating with the rim shaft. The pins on the pin wheel are adjusted at various distances apart, according to the required number of the twist of the yarn, and the blank part of the wheel allows time for the coming out of the carriage. The aforesaid cam shaft, after each movement, is held steady by a lever and lock wheel, and the movements are performed with ease and certainty. *Patent abandoned.*

8. R. A. BROOMAN. *Improvements in shears or scissors.* (A communication.) Dated Jan. 1, 1862.

This invention is intended chiefly to be applied for severing the large threads surrounding net, tulle, and machine-made lace, for which purpose ordinary scissors have been hitherto used. The invention consists in the arrangement of several pairs of cutting blades in one and the same instrument. Two plates, the lengths of which are regulated according to the number of cutting blades employed, are connected to handles; the cutting blades of the scissors are secured to the plates by screws inserted in slots formed in them; a guard-plate covers the heads of the screws which secure the upper cutting blade to prevent the threads catching in them. The ends of the upper blades are beveled, which, in combination with guides formed of thin metal connecting two adjacent cutting blades, guide the threads to be cut between the two blades. Springs between the handles keep the blades apart until pressure is applied to them. *Patent completed.*

9. R. A. BROOMAN. *Improvements in supporting and propelling vessels.* (A communication.) Dated Jan. 1, 1862.

This invention consists in supporting vessels on the water, and propelling them by means of two or more sets of drums, one set or all of which is or are armed with floats or paddles. The vessel may be cylindrical, and may be made conical, or of any other convenient shape, both at bow and at stern. It is supported clear of the water, but may be furnished with a keel entering the water. The paddle drums are driven by steam or other power contained in the vessel. The vessel may be suspended from the drum shafts by strong springs, similar to those used for locomotive engines. The vessels may be furnished with one or two rudders. *Patent abandoned.*

10. W. BUSH. *Improvements in omnibuses and other carriages.* Dated Jan. 1, 1862.

This consists, 1, in constructing omnibuses and other carriages with parts thereof double, so that the bottom, sides, and top may, when required, be drawn out, and afford increased accommodation. 2, in a method of constructing trucks and carriages, so that they may be used on rail or tramway and on common roads. *Patent abandoned.*

11. B. RHODES. *Improvements in forming or making straight and bent pipes, and bends for pipes, and also vessels, and in coating and protecting objects and articles of various forms intended to be employed for various purposes.* Dated Jan. 1, 1862.

This consists in using elastic fabrics in combination with bitumen or bituminous mastics or compositions, for the purpose of forming vessels of various kinds of regular and irregular shapes, and also covering or coating various articles and things for the purpose of protecting them, rendering them capable of resisting the action of moisture or atmospheric influence, as also for the purpose of rendering them more perfect non-conductors of electricity, as well as to render articles so coated subservient to other useful purposes. *Patent completed.*

12. E. BANFIELD. *Improvements in lubricating and maintaining in working order axle journals and brasses, applicable also to other journals and bearings.* Dated Jan. 1, 1862.

This consists in using hay, straw, grass, hemp, or hair, manufactured or unmanufactured, or the shavings or clips of wood, which are filled into or packed in the axle-box or reservoir containing the oil or lubricating fluid, used for lubricating and maintaining in working order, by capillary attraction, the working surfaces of journals and bearings. *Patent abandoned.*

13. W. B. PATTRICK. *Improvements in the manufacture of sugar, and in the apparatus employed therein.* Dated Jan. 1, 1862.

Here the patentee makes use of a closed vessel or vacuum-pan, and he heats the saccharine syrups or solutions therein to a low temperature, considerably below the boiling point, or 212° Fahr., by hot water, air, or vapour, caused to circulate in pipes in or around such vessel, or in the jacket or outer case thereof, combined with the use of air heated to about the same temperature forced through openings in a pipe or pipes, applied so that the air may be distributed amongst, and pass through, the syrup or solution, and thereby aid in driving off the aqueous particles contained therein in the form of vapour, which are then drawn off by the air-pump or other means. By these means improved colour and increased amount of crystals will be obtained with less molasses or treacle. *Patent completed.*

14. E. F. DAVIS. *Improvements in gas burners.* Dated Jan. 1, 1862.

The object here is to cause the gas, while passing into and through the burner, to become regulated and controlled with regard to its pressure, to be at the same time purified, its illuminating power increased, and its consumption economised. The lower part of the burner consists of a receptacle containing charcoal; above the charcoal a perforated cover or disc, having the edge furnished with a screw thread (immediately below which is a gauze wire to prevent the charcoal stopping up the perforator), is screwed down inside the receptacle, which has a corresponding thread cut therein, so as to form a cap, and force down the charcoal, as may be required according to the pressure of the gas. The upper part of the burner consists of a dome and a nipple screwed thereon, the interior and upper portion of the dome being furnished with a double layer of wire gauze, a similar duplicate layer being placed in the lower portion of the burner beneath the charcoal. The dome is to be screwed on the lower part of the burner, and the whole is then ready to be attached by a male or female screw at the bottom of the burner to the gas pipe. The gas will then pass through the layers of gauze, and through the charcoal and perforated disc into the dome, and through the upper layers of gauze into the nipple, becoming in its passage not only purified or rendered smokeless and increased in its illuminating properties, but regulated in its passage, and its consumption proportionally economised. *Patent completed.*

15. J. HOWARD and E. T. BOUSFIELD. *Improved apparatus applicable to steam cultivation.* Dated Jan. 1, 1862.

This consists, 1, in an improved snatch-block. The addition of a guide or friction-roller is made to the ordinary double snatch-block, which block, when in use, is placed in front of the windlass, the ropes being carried from the pulleys of the snatch-block in any required direction. It relates, 2, to the construction of double-action ploughs or cultivators to be operated by steam-power, and consists in an arrangement for suspending the ploughs out of work, and in a simpler and better arrangement than has heretofore been adopted for steering the implement. *Patent completed.*

16. W. E. NEWTON. *Improvements in coffee-pots and boilers for culinary purposes, part of which improvements are also applicable for generating steam.* (A communication.) Dated Jan. 1, 1862.

This consists, 1, in combining a coiled tube with a boiler, central tubes, and perforated food-holder or receptacle, so that, when the heat is applied to the apparatus or device, and the water commences to be heated, a circulation or current will be formed within the boiler, and the water very expeditiously heated and boiled, while the substance or material to be boiled or decocted will be disposed in the most advantageous manner in the current of water to favour the cooking or extracting process. 2, in using in connection with the boiler or coiled tube and food-holder, or receptacle aforesaid, one or more supplemental chambers or vessels, placed under and over the other, and communicating with each other and the boiler by a tube or tubes constructed and arranged to favour the ascent of steam or heated air, with the supplemental chambers for warming or cooking articles of food, and at the same time serve as a means to keep the cover or lid of the receptacle or boiler in proper position. *Patent abandoned.*

17. J. J. GUTKNECHT. *Improvements in meters for measuring gas, water, and other fluids, under any pressure, even the smallest, without making any change in the apparatus.* Dated Jan. 1, 1862.

The patentee claims, 1, the arrangement of fluid-measuring apparatus, in which the capacity of the measuring chamber is controlled by a piston and flexible diaphragm, by whose motion the quantity of fluid passing through the water is indicated and registered, all as described. 2, the arrangement of parts described as applied to a fluid meter, whereby the valve which regulates the admission and escape of the fluid to and from the measuring chamber is caused to change its position quickly at the completion of the stroke of the measuring piston or diaphragm by the action of springs placed in position for that purpose, as described. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated April 14, 1862.

1072. J. Childs, Victoria Street, Pimlico, gentleman. Improvements in the manufacture of wax matches.

Dated May 22, 1862.

1553. G. F. Göransson, Gefle, Sweden, iron master. Improvements in the construction and arrangement of armour plates, applicable to ships, forts, batteries, and other structures, and to a mode of securing the same.

Dated May 30, 1862.

1625. P. U. Payras, 15 Passage des Petites Ecuries, Paris, commission agent. Improvements in protecting dry or green hides from vermin.

1626. J. Gurrin, Stroud, Gloucestershire, woollen merchant. A new mode of telegraphic communication between separate buildings or parts of buildings.

Dated June 4, 1862.

1679. C. S. Cahill, 9, Gerrard Street, River Terrace, Islington, gentleman. Improvements in the manufacture of felted fabrics suitable for hats, bonnets, and other purposes.

Dated June 9, 1862.

1717. E. Hottin, 26 Rue de Rivoli, Paris, agent. A composition for rendering uninflammable linen, flax, silk, cotton, wood-work, and other articles or materials.

1722. A. J. Joyce, Cambridge Terrace, gentleman. Improvements in lighting and heating.

Dated June 12, 1862.

1747. I. Spight, Glandford Briggs, Lincoln, ironfounder and agricultural machine maker. Improvements in horse hoes

1749. A. A. Lerenard, 60 Boulevart de Strasbourg, Paris, practical engineer. A new and improved cement or mastic for making joints of steam, water, or gas pipes or chambers.

1753. B. George, Kingsland Road, gentleman. Improvements in the construction of portable beds, bolsters, pillows, and sofa and other cushions.

Dated June 13, 1862.

1755. W. Smith, 48, Briggate, Leeds, merchant. Improvements in apparatus for cutting or dividing soap.

1757. A. Longbottom, Hammersmith. Improvements in the manufacture of artificial stone.

1759. J. H. Glew, Howland Street, Fitzroy Square. Improvements in sewing machines.

1761. T. W. Fleming, 10 Lancaster Gate, Bayswater. Improvements in preparing charges for fire-arms.

1763. W. E. Newton, 66 Chancery Lane. Improvements in fire-arms, and in the attachment of bayonets or swords thereto. (A communication.)

1765. J. Ives, New York, U.S. Improved apparatus for expressing juice from fruit and other vegetable substances.

Dated June 14, 1862.

1769. J. Sawyer, Noble Street, engineer, and G. Padgham, Dalston, gentleman. Improvements in steam boiler and other furnaces, applicable in part to grates of various kinds.

1773. W. Bouch, Shildon, Durham, engineer. Improvements in cranes.

1775. W. Wighton, Edinburgh, watchmaker. Improvements in apparatus for regulating watches and other time keepers.

Dated June 17, 1862.

1796. J. Kellow and H. Short, Delabole, Cornwall, mineralogists. Improvements in the manufacture of blasting powder.

Dated June 19, 1862.

1805. A. Howat, Farnworth, near Bolton-le-Moors, Lancashire, brassfounder. Improvements in the construction of water gauges and blow-off taps for steam boilers and other purposes.

1807. W. Stokes, Birmingham, gun barrel rifler, and C. W. James, Birmingham, gun manufacturer, and J. Stokes, Birmingham, gun barrel rifler. New or improved machinery for stocking and screwing guns and pistols.

1809. C. Cartwright, 1 Liverpool Street, Moorfields. Improved means of stopping or retarding trains on railways.

1811. E. J. Davis, West Smithfield. Improvements in treating and preparing food for horses and other animals.

1813. W. Thomson, Thorney Gas and Water Works, Thorney, near Peterborough. Improvements in machinery for making bricks, tiles, and other articles.

Dated June 20, 1862.

1815. J. G. Dupuch, Paris, brassfounder. Improvements in cocks for regulating the supply of gas.

1817. W. E. Gedge, 11 Wellington Street, Strand. Improvements in the manufacture of candlesticks, and in machinery or apparatus used in such manufacture. (A communication.)

1818. J. Bedford, 52 Rue Charlot, Paris, manufacturer. Improvements in the irons and cutters of planes, and in the methed of manufacturing the same. (A communication)

1819. W. Malins, Pershore, Worcestershire. An improved protective covering for agricultural or other similar purposes.

1821. B. M. Mody, 4 Trafalgar Square. Improvements in varnish or polish

1822. J. W. Taylor, Newsome, near Huddersfield, manufacturer. Improvements in valves, and in means for regulating and indicating the flow and pressure of fluids.

1823. D. Middleton, Burton-by-Lincoln, agriculturist. Improvements in cranes for lifting weights into and out of carts, and for other purposes.

1825. A. Warner, Threadneedle Street. Improvements in the manufacture of pigments or paints from certain refuse materials.

Dated June 21, 1862.

1831. G. Simpson, Glasgow, civil and mining engineer. Improvements in machinery for working, boring, and mining or excavating tools, and mine and other pumps.

1832. H. and J. Davenport, Bradford, Yorkshire, reed and heald makers. Improvements in means or apparatus for the manufacture of loom healds or harness.

1833. J. Anderton, Accrington, Lancashire, manufacturer. Certain improvements applied to the tape-leg or sizing machine, and in the apparatus employed therein, for the purpose of improving the yarn.

1834. S. Holman, 18 Cannon Street, engineer. Improvements in pumps and valves.

1837. J. H. Redstone, Indianapolis, Marion, U.S., engineer. Improvements in the construction of boilers of steam engines. (Partly a communication.)

1841. E. Edmonds, Berryfield, Wilts. Improvements in the manufacture of felted articles and fabrics, and in the apparatus employed therein. (Partly a communication.)

Dated June 23, 1862.

1843. H. McKenzie and P. Ramsay, Glasgow, manufacturers. Improvements in cylindrical or circular brushes or rollers for various manufacturing machines.

1844. H. Ponsonby, Liverpool, provision merchant. Improvements in top sail sheet bits or bolts.

1847. W. Barr, Coventry, designer. An improved manufacture of raised or brocaded fabrics woven in cotton or flax, either alone or in combination with wool.

Dated June 24, 1862.

1849. A. Ripley, Brook Street, West Square, Lambeth, engineer. Improvements in the construction of damper governors or regulators.

1850. W. Hargreaves, whitesmith, and G. H. Leather, worsted spinner, Bradford, Yorkshire. Improvements in machinery or apparatus for combing wool, hair silk, cotton, flax, and other fibrous substances.

1851. T. Carr, New Ferry, Chester, glue manufacturer. An improved machine for grinding, kneading, washing, and other like purposes.

1853. G. Collier, Halifax, and J. W. Crossley, Brighouse. Improvements in means or apparatus for hot pressing, which improvements are also applicable to other heating purposes.

1857. E. C. Nicholson, Atlas Works, Locksfields, manufacturing chemist. Improvements in the preparation of colouring matters applicable to dyeing and printing.

Dated June 25, 1862.

1859. M. A. F. Mennons, 24 Rue du Mont Thabor, Paris. Improvements in steam boiler furnaces. (A communication.)

1861. J. Blair, Caledon Mill, Manchester, wadding manufacturer. Improvements in the manufacture of wadding.

1863. G. Haseltine, 100 Fleet Street, American barrister-at-law. Improvements in vaporising lamps, for burning petroleum or coal oil. (A communication.)

1864. F. Tolhausen, 17 Rue du Faubourg, Montmartre, Paris, civil engineer. An improved lock or locking apparatus. (A communication.)

1867. E. H. Huch, Brunswick, and F. J. Windhausen, Duderstadt, Hanover. Improvements in caloric engines named 'fire-air engines.'

1869. G. Turner, 13 Rose Terrace, Brompton, machinist. Improvements in mincing apparatus, such improvements being also applicable to machines for grinding coffee and spices.

1871. W. Clark, 53 Chancery Lane, engineer. An improved frame for holding photographic pictures. (A communication.)

Dated June 27, 1862.

1884. E. Hunt and H. D. Pochin, Salford, chemists. An improved condensing apparatus.

1886. J. Lord, Todmorden, machine maker, and J. Brown, Burnley, overlooker. Certain improvements in power looms for weaving.

1888. R. A. Brooman, 166 Fleet Street, patent agent. A method or methods of preparing paper for the reception of photographic pictures or impressions, in order that the said pictures or impressions may be transferred to and fixed on wood, porcelain, and other surfaces. (A communication.)

Dated June 28, 1862.

1898. J. Garnier, Devonport, lieutenant in the Royal Engineers. Improvements in ordnance and in projectiles.

1904. N. Thompson, 15 Abbey Gardens, St. John's Wood. Improvements in apparatus for stopping bottles, jars, and other vessels, and in instruments for applying and removing such stopping apparatus.

Dated July 1, 1862.

1914. J. Parkinson, Bury, engineer, and J. Marsland, Newchurch, engineer. Improvements in apparatus for regulating the flow and pressure of steam and other fluids.

1916. E. Pourpoint, 15 Passage des Petites Ecuries, Paris, linen draper. An improved wool washing machine.

1918. C. Lungley, Deptford, ship builder. Improvements in constructing, building, and working floating docks and other floating bodies, and in pumping apparatus to be employed therein.

1922. J. M. Dunlop, Manchester, engineer. Improvements in cotton gins.

Dated July 2, 1862.

1926. J. James, Uskside Iron Works, Newport, manufacturer. An improved mode of welding railway crossings.

1928. B. Johnson, Chester, engineer. Improvements in rope wheels for mines, collieries, and other similar purposes.

1932. J. Steel, Stirling, plumber. Improvements in water-closets.

1934. J. Webster, Birmingham, engineer. Improved apparatus for the manufacture of gas for illumination.

1936. J. M. Hetherington, Manchester, machine maker, and T. Jackson, Stockport, manager. Improvements in machinery or apparatus for preparing, spinning, and doubling cotton and other fibrous materials.

Dated July 3, 1862.

1938. G. H. Birkbeck, 34 Southampton Buildings, Chancery Lane, engineer. Improvements in the construction of mechanical horses. (A communication.)

1940. W. M. Williams, Handsworth, Staffordshire, teacher. Improvements in apparatus for the distillation of coal and peat and such other substances as are or may be used for the manufacture of solid and liquid volatile hydro-carbons.

1942. T. O. Dixon, Steeton, bobbin manufacturer. Improvement in means or apparatus for heating or warming rooms or buildings with steam, and in carrying off the condensed steam or water therefrom.

Dated July 8, 1862.

1967. O. W. Child, New York. A new and useful composition to be used in shaft journal boxes. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

562. A. E. Ragon. Electric alarums. (A communication.)
563. A. Potts. Vegetable substances.
564. P. Robertson. Manufacture of ammoniacal salts.
566. J. G. Jennings. Construction of chimneys or flues.
568. L. Martin. Candle lamp.
576. J. Schofield. Looms.
579. A. Bedborough. Pillar letter-boxes and letter-bags.
586. J. Ellis. Fastening chains.
588. P. and F. Schafer. Travelling bags.
604. J. Barker. Casting drums, pullies, gear, and other wheels.
607. J. G. Shipley. Bridle-heads, reins, and bits.
608. M. B. Newton. Drain pipes.
609. T. Farrimond. Safety cage.
611. J. Carpendale and T. Middleton. Chasing on copper.
613. T. Ball, W. Ball, and J. Wilkins. Warp fabrics.
614. R. Wright. Heating and clarifying saccharine fluids.
622. A. Blair. Rotatory engines.
623. W. Paterson, W. A. Sanderson, and R. Sanderson, jun. Finishing woven fabrics.
625. J. Platt. Cleaning cotton from seeds.
626. J. Deane. Revolving fire-arms.
631. W. Palmer. Manufacture of candles.
632. J. Fleming. Pressing cotton. (A communication.)
640. R. A. Brooman. Producing drawings by the aid of photography. (A communication.)
656. O. and J. Kerautret. Construction and ornamentation of buildings.
657. E. G. Camp. Brushes.
659. T. B. and W. Wilson. Splitting cane.
664. A. René Le M. de Normandy. Connecting gas and other pipes.
673. P. Gondolo. Baking oven.
679. W. E. Newton. Manufacture of cartridges. A communication.
684. J. Hunter. Apparatus for removing slag from furnaces
695. J. B. Howell. Manufacture of chains and chain cables.
701. A. Quinard. Horse shoe nails.
707. G. T. Bousfield. Machinery for digging and disintegrating the earth. (A communication.)
713. H. Emanuel. Manufacture of ornaments.
731. L. P. Mongruel. Cold vapour generator.
732. W. Bowser. Ships' fire hearths.
754. A. A. Beaumont and J. A. Escalier. Flying top.
1084. A. V. Newton. Manufacture of blasting powder. (A communication.)
1178. G. N. Bates. Dressing lace and other fabrics.
1189. W. E. Newton. Manufacture of imitation lace, net, or open-work fabrics. (A communication.)
1215. J. Shaw. Engines and indicators. (A communication.)
1559. J. Ward. Manufacture of textile or looped fabrics.
1733. J. G. Appold. Regulating the discharge of water and other liquids, and air and other gases.
1775. W. Wighton. Regulating watches and other timekeepers.
1830. J. Taylor. "Doffer" or "stripper" for carding engines for preparing cotton and other fibrous substances.
1850. W. Hargreaves and G. H. Leather. Machinery or apparatus for combing wool.
1886. J. Lord and J. Brown. Power looms for weaving.
1967. O. W. Child. Composition to be used in shaft journal boxes. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed July 11, 1862.

107. S. W. Marsh.
108. T. Harrison and J. G. Harrison.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JULY 25, 1862.

THE CONSTITUTION OF THE ADMIRALTY.

In the history of the world, from the earliest ages up to modern times, mystery has been one of the most, if not the most, powerful means of government. The Lama of Thibet in his inscrutable nonentity, the veiled prophet, the Council of Ten, the terrible tribunal of Loyola, the eccentric brotherhood of Freemasons and Odd Fellows, have, through the agency of the unknown and the incomprehensible, exercised unbounded influence over their followers, their suppliants, or their victims, and gained power or popularity by the inscrutable character of their organisation and proceedings. But of all the mysterious institutions which ever existed and afforded food for the historian, the poet, and the dramatist, there is none to be compared to the English Admiralty for the profound intricacy and hopeless impenetrability of its mode of conducting the naval administration of this country.

The number of communications we receive from persons who have suffered cruel neglect from the dull routine of that department, and the facts which have come to light in connection with the revolution in naval construction which is now in progress, lead us to believe that we shall render a great public service by laying bare the mysteries of Admiralty mismanagement.

At this moment there is no question of more vital importance to the nation than the reconstruction of the navy. If she is to maintain the empire of the seas, England must possess the best appointed and most efficiently protected armour-plated fleet in the world. We have published much on this subject; but, in the end, we know our countrymen will acknowledge that there never was a case that required a more vigilant supervision than the manner in which the public money is wasted and the national security imperilled, by the incapacity of the officials in the naval department to grapple with the vast undertaking of constructing iron-cased men of war. Under the mask of pompous formalities and unmeaning routine, with the aid of parliamentary effrontery, absurd blunders are committed and concealed; great authorities, as they are termed, gain the official ear, and, by not opposing the prejudices of the Controller's department, secure their own ends; whilst the counsels of able men, expressly appointed to advise the Admiralty, if they do not coincide with the views of the executive, are wholly disregarded.

Having made these introductory remarks to arrest the attention of our readers, we come to facts.

Something has already been made public, by recent experiments at Shoeburyness, about the terrible blunder of the Government constructors in the plan of armour-plating a new class of frigates exceeding the Warrior in dimensions, power, and expense. Four vessels of this class are under construction, namely, the Minotaur, the Northumberland, the Prince Albert, and the Agincourt, and will cost more than a million. Other classes of iron-mailed ships are being constructed, including Mr. Reed's singular combination of wood and iron.

In defiance of past experience, Government have repeated the folly of adopting modes of construction and systems of armour-plating without making any previous trial. With the history of the Warrior before them, it is inconceivable how the Admiralty can again commit so great an error. We are naturally led to consider what is the cause of this neglect of duty, and we have been at some pains to investigate the subject. The result of our inquiry is not satisfactory. The construction of the Warrior without any previous experiment trials; the mistakes in some of her arrangements, which target trials at a small expense would have prevented; the never-ending alterations in some parts of her structure; the alarming accounts of her inefficiency as a fighting and a sea-going ship; the mystery and contradictions about the experiments at Shoeburyness, of which the object is to test the relative value of guns and iron armour, and improve the construction of both; the hasty and inconsiderate adoption of designs for the new classes of ships referred to — all these circumstances, carefully passed in review, bring us to the conclusion that in the administrative and executive departments of the Admiralty there exists an amount of prejudice, a want of practical knowledge in iron ship-building, and a total absence of engineering ability, or experience for the construction of naval armour, which are obstructive to improvement, damaging to the national interests, and the source of extravagant and wasteful expenditure. For these evils there is no remedy but a radical reform and reorganisation of the Admiralty.

Some of the abuses of the system are so manifest, they only require to be mentioned to become apparent. The Lords' Commissioners, that is, the administrative branch, refer all questions of construction to the Controllers of the Navy, who represent the executive branch, where it is considered that all the constructive knowledge, scientific and practical, requisite in naval architecture, is concentrated. But, in fact, what is the composition of that department? We find in it a valuable accumulation of knowledge in wooden ship-building, founded on careful training in the school of naval construction, and practical experience in the Government dockyards. The officials, who by merit or seniority have been promoted to the head of the constructive department, and who, in fact, are its directors, under nominally the orders of the Controller, are disciples of the wood school, believe in wood, are prejudiced against iron, and have no knowledge of iron naval architecture but what they have picked up in the yards of iron ship-builders. They are learning their lesson in iron, and no doubt have made the most of their opportunities, but they are not competent to direct the counsels of the Admiralty for the construction of iron ships. When we come to naval armour, the important discovery of yesterday — which is engineering science of the highest order — the deficiency is greater, in fact, absolute. Its first elements are not understood; how should they be? How can men, who have passed their lives in learning the theory and practice of the construction of wooden vessels, know anything about iron ships or iron armour? One might as well expect a carpenter or a joiner to be an adept in a blacksmith's or an engineer's work. The Controller of the Navy is not expected to be a practical ship-builder or an engineer.

This statement of facts gives us an insight into the secret working of our naval administration. The Lords refer every technical matter relating to naval construction to the Controller; the Controller refers to assistant officers who are incompetent to give sound advice on iron ships or naval armour; and the result is what might be expected, that, with the utmost good will on the part of these official counsellors, the opinions they hold and the conclusions they come to are not reliable.

To do the Lords' Commissioners justice, they are perfectly aware of the inadequacy of the Controller's department to come to right conclusions, or to give good advice on many points relating to iron ships and naval armour. In order to enable the Admiralty to obtain sound practical information on the matters which the Controller's department do not understand, the special committee on iron, composed of men whose aptitude for the duties which devolved upon them, were so warmly and deservedly eulogised by the Secretary for the Admiralty, a consulting committee of four eminent iron ship-builders, and a special committee on coppering iron ships, were appointed, and experiments with guns on iron plates at Shoeburyness and Portsmouth, have been carried on extensively, under the direction of the first-named committee.

When, however, we come to investigate the proceedings of the Admiralty in constructing armour-plated men-of-war, we find them characterised by a lamentable perseverance in the old system of reference from the Lords' Commissioners to the Controller's department, and an almost total disregard, in a practical sense, of the valuable teachings of experiments comprised in the reports and recommendations of the committees which were formed for the guidance of the Admiralty.

The reason of these results — or rather no results—is departmental jealousy. The public service is suffering so greatly, and the public money is wasted so lavishly, the truth must be spoken. The only means of overcoming these evils, which are the cancer of the national exchequer, is a reconstruction of the department which, by the mere *vis inertia* of obstruction, puts a stop to improvement, spends millions in waste, and impedes the development of correct and intelligent principles for the construction of an iron navy on a sound, durable, and economical plan.

To prove that the view here presented of Admiralty administration is not unfounded or overdrawn, we will give a few illustrations.

When, more than two years ago, it was decided to construct armour-plated iron ships, the most eminent iron ship-builders, at the request of the Admiralty, sent in designs for the new class of men-of-war. We have the testimony of Mr. Laird, one of the firms which furnished designs, that no attention was paid to the plans and suggestions of himself and other practical ship-builders; but the Warrior-type, designed by the Controller's department, was adopted as the plan of construction for six large vessels, which were ordered to be laid down about the same time. There are differences of dimensions, form, and armament in these vessels, but in the main features of their construction they are all alike. The ordinary plan of iron ships built for the commercial navy was adopted, without any provision for strengthening the frames and skin in the manner required by the enormous weight of armour which they had to carry. The system of armour-plating was a fac-simile copy of that of the La Gloire, fastened with through-bolts to timber backing, and the addition of what was considered a great improvement, tonguing and grooving the edges of the plates.

Before these six vessels were built, and up to the time of launching all of them, no experiment was made to test the efficiency of a system which was applied to them simulta-

neously at an expense of nearly two millions. Any private speculator on a scale not so colossal would have made some trials before embarking his capital; but this thought never occurred to the Admiralty. Many months after the Warrior was at sea, the experiments of the iron-plate committee gave rise to misgivings in the Admiralty mind. A section of the Warrior was constructed as a target and submitted to the fire of artillery at Shoeburyness. The force of heavy projectiles soon showed the defects of the mode of armour-plating adopted. The supposed improvement of tonguing and grooving turned out a serious blunder: it had cost an extra expense of some £10,000 or £12,000 for the Warrior, and as much more for every other ship to which it was applied. This sum would have been saved if a Warrior target trial had been made before the plan of tongueing and grooving was finally adopted. The through-bolt fastening and perforation of bolt holes in the plates are recognised as the source of destruction to the plates; and the wood backing affords no support sufficient to prevent the armour plates being bulged, driven into the wood at the places struck, and buckled at the ends. The frames and skin were ascertained to be too weak for the weight of armour hung upon them by the points of the bolts. Two years ago a few thousand pounds spent in experiments would have solved all these points and saved immense sums, for we see it looming in not a very remote future, that every vessel cased with iron on the plan of the Warrior will have to be stripped of her armour and protected with a better devised system.

One would have thought that this experience would have brought the Admiralty to a more rational mode of proceeding, but the blindness of routine is incurable. Six more iron-clad ships are being built, and, regardless of the warnings of the experiments at Shoeburyness, the Admiralty have ordered them to be covered with armour plates on the Warrior plan, with the exception of relinquishing tonguing and grooving, reducing the thickness of the teak backing, and increasing that of the armour plates; but the objectionable methods of fastening with through-bolts, perforating holes in the plates and wood backing, are retained. The lessons learnt by the experiments on the Warrior section are thrown away; but, what is worse, insurmountable obstacles are opposed to promising plans *recommended by the iron-plate committee.*

It will be alleged that several plans of armour-plating have been tried with targets, ordered by the Admiralty, including those on the Fairbairn, Samuda, and Scott Russell systems, and not one of them have been proved to possess powers of resistance equal to those of the Warrior section. This is only partially true, and, if established as a fact, it does not prove that no better plan can be discovered, nor does it justify a reckless perseverance in an avowedly imperfect system, without a trial of other plans which have long ago been submitted to the Admiralty and recommended for trial by the iron-plate committee.

It is a fact which we are enabled to make public on undoubted authority, which demands the most serious scrutiny, that the committee, in their report, which is so mysteriously withheld, recommended five plans of naval armour for trial, neither of which the Admiralty has ordered to be tried. On this matter there is a state of antagonism between the committee and the Controller's department, the grant of money to try the plans approved by the former being refused on the ground of economy; but no thought is taken of the extravagant experiment of armour-plating ships on a plan acknowledged to be defective.

The parsimony which appropriates hundreds of thousands of pounds to repeat a system known by trial to be ineffective, and refuses the funds for experiments on well-considered plans, may truly be said to be "straining at a "gnat and swallowing a camel." We shall return to this subject, and show how the sanction of the Admiralty for target trials at the public expense is obtained in some cases and withheld in others.

INTERNATIONAL EXHIBITION.

MARINE ENGINEERING.

Now that the Jurors' Awards are made, we may fairly enter into a minute examination of what the Exhibition presents to us as examples of the marine engine practice of the present day; at least, as respects this country and several of the most important seats of manufacture on the Continent. We have reserved our remarks upon this subject—one of the most important which any mechanical journal can consider—not only on account of the numerous additions which have from time to time been made to the collection, both in the way of drawings and models, since the day of opening, but also in order that we may do justice to those who, from one cause or another, were unable to present their plans either upon the scale, or in the form best fitted for attracting the attention of the jurors, or, lastly, within the time specified in which the jurors' reports had to be completed, and their awards made.

We do not for a moment mean to insinuate that the jurors, in the execution of their arduous duties, did not fairly consider the various objects to which their attention was called, or that they willingly or purposely overlooked anything exhibited at the time their examinations were made; but we do know that in several cases, from omissions in the catalogue, as also from the absence of any systematic plan of inviting *every* exhibitor to meet them to explain his production, no small amount of injustice has been done. We also know that, upon the attention of the jurors being called to some of these cases, they have subsequently expressed their sincere regret that means were not adopted for bringing to their knowledge any omissions prior to the termination of their labours, which they were unable to extend beyond the middle of last month, with the single exception of a few extra days given to examine objects sent from some of the colonies, the arrival of which had been unavoidably delayed.

Each exhibitor has sent, if not what he liked, at least what he could; and unless those for whom some of the marine engines have been made had been willing for them to be sent to the Exhibition, either the manufacturer would not have exhibited anything, or else what now is represented by a 400 or 600-horse power engine would have simply been shown in a model or a drawing. The means, or want of means, of some of the exhibitors, has had much to do with the mode in which the things they have exhibited are presented to the public. Those who could not or would not afford to make engines of any size, contented themselves with models or drawings, the models being either of a showy or attractive character, and exhibited in motion, or of a more humble nature, made of wood and without arrangements for showing them at work.

Now, although we have no desire of blaming the jurors for either much they have done or left undone, we cannot fail to notice that most of the exhibitors of marine engines, and, indeed, of articles of all kinds as well in the marine engine class as in other classes, who have exemplified their manufactures by very large and imposing pieces of workmanship, have invariably been the most successful in obtaining favourable notice from the jurors. Yet it will be seen at once that such machines mostly represent only what has been done over and over again; not that they are the less valuable articles for exhibition on that account, perhaps, but still calculated to throw unduly into the shade such productions as are of a more progressive nature, and which are more often represented by models or drawings.

We do not forget that the manufacturer of an article well made and fully answering its intended purpose, however old in design that article may be, might fairly have a medal awarded to him; although the originally understood condition of space being given, was that the article exhibited should have been produced since 1851. What we object to is, that proposals for constructing engines or other things in a new way or on a new plan, should have been so suspiciously looked upon by the jurors, as they evidently have been. It is true that in the instructions given to them, they were specially warned not to award medals for untried inventions, except with the utmost caution, so that we must blame the Commissioners rather than the jurors, although there are many signs of the jurors having acted upon these instructions with unnecessary exactness.

It is almost needless for us to inform our readers that new projects do not often emanate from well-established manufacturers in any trade. Their interest mostly lies in repeating, in the greatest numbers possible, whatever they manufacture; loss of time, extra cost, to say nothing of mental labour, being more or less involved, and sometimes very deeply involved, in the production of new machines, or the introduction of new features in old ones. We do not deny that, as a matter of trade policy, the opposition of many manufacturers to change, or the improvement of engines or tools made by them, is right; but this fact only renders it of the greatest possible consequence, that in awarding prizes upon occasions such as the present Exhibition, the judges should pay the most minute attention to new projects exhibited, not passing by anything, however roughly or inadequately represented, until they have well examined it and ascertained its merits or otherwise. These gentlemen would, no doubt, repudiate with great indignation the idea that they had in any case done this, but we happen to know that they have done so, although we frankly admit that they have done so unwittingly.

We shall next week show in what instances signs of this disrespect, for *schemes* as they are frequently invidiously called, are apparent, merely observing now that in no case have the jurors stumbled over a 600-horse power engine without being made fully aware of its existence. In judging of the merits of any machine, we fully admit the immense amount of responsibility which the knowledge of the fact of its being the tenth, twentieth, or fortieth, made from the same patterns, at once removes; and we feel fully also the responsibility of expressing an opinion on an untried arrangement, be it for what purpose it may. If there are some people who like to think, there are, doubtless, many more who prefer not having to think at all—who most willingly hand this work over to those who, they are willing to persuade themselves, are much better able to decide upon difficult questions than themselves. Who,

in having to judge of the merits of a marine engine, for instance, would not feel a great weight removed from his shoulders if he ascertained that Messrs. Maudslay or Penn had adopted it or approved of it? Without for a moment suspecting himself of deferring to authority, or of not exercising his independent judgment in the matter, we can hardly doubt that a person, however competent he might be to form a correct opinion himself, would much more readily arrive at a conclusion and with infinitely less trouble, than he would do were the knowledge of the fact referred to withheld from him. He would, in reality, have had more than half his work done for him, so leaving him a comparatively easy task to perform. This respect for authority it is, of course, very difficult to avoid feeling, although, whenever things have to be judged of on their own merits, it would be highly desirable that the judges should know as little as possible of either the makers or the number made.

We think it would not have been too much to expect the jurors of the several classes to go fully into, and express an opinion of the probable advantages of, arrangements proposed, although they might never have been practically carried out. In awarding a medal for an untried invention, they could have stated in every case the circumstances under which their approval was given, and by this means avoided the risk of setting an undue value upon any article whose efficiency had not been proved. We are aware that the executive of all our scientific institutions combine in setting their faces against communications on proposed undertakings, as against those descriptive of what has actually been done; but we protest strongly against this disinclination to examine schemes. If an engineer, upon being called upon to design, say a machine for an entirely new purpose, or to improve an old machine, does so to the best of his ability, and is then desirous of submitting his plans to his professional brethren before incurring the expense of carrying such plans into execution, we maintain that the rules of no society should prevent his doing so; and further, that it is the duty of those who belong to such societies to give him what aid they can in suggesting alterations in his design, if such shall appear to them desirable. It is no answer to this idea of the duties of the elder members of scientific societies, to say that few engineers would avail themselves of this mode of testing the probable soundness of their views: this may be so, but in many cases it would save both much useless expense and anxiety. The well-known fact, that communications of the kind referred to are almost universally discouraged, prevents persons making any attempt at offering them.

When a thing has been made, and tried, and found successful, it is, of course, of immense importance to professional men to know the particulars and results; but is it not also of equal importance that engineers should discuss the best modes of working out problems as yet unsolved? We have little need for discussion about plans the success of which practice has confirmed; it is schemes, and those almost alone, that need it.

About 240 tons of iron ore are raised daily for shipment at the Jackson mine, Marquette, Lake Superior.

Iron sleepers have been laid down on the Madras (Indian) railroad, in place of wooden sleepers. It has been found that wooden sleepers decay so rapidly in tropical climates, that iron has been resorted to as a more economical material. This railroad is 406 miles in length, and stretches across the Indian Peninsula from Madras to Beypoor.

THE POST OFFICE.

A LECTURE BY MR. COMMISSIONER HILL, RECORDER OF BIRMINGHAM.*

THE first indication of a letter post is stated by German authors to have been found in the republic of the Hanse Towns as early as the thirteenth century. Shortly afterwards it was adopted by the Teutonic knights, who, like him of the "Canterbury Tales," made war on the infidels in Lithuania and the adjacent districts eastward. We may next trace a line of posts in the Tyrol, laid down in the reign of the Emperor Maximilian, who naturally desired to connect Lombardy with his Austrian dominions. The merit of this project is given by historians to the Lombard princes of the house of Thurn and Taxis, as they were designated after their removal to Germany. Under the Emperor Charles V. they established a line from Vienna to Brussels, thus connecting the Empire with its outlying possessions in Flanders. Until the reign of Henry VIII., letters in England were conveyed by special messengers—sometimes on foot, sometimes on horseback—and, again, by carriers, who, as we learn from Shakespear, had no relays, the same horse either carrying its pack or drawing its cart from day to day. How far England was behind some other nations in very important social arrangements, is indicated by the circumstance that long before we had a post for inland letters, the foreign merchants resident here enjoyed a stated interchange of correspondence with the Continent. This undertaking had its origin during the reign of Henry VIII., or prior to its commencement. In that of James I., from a complaint by the English merchants that the foreign postmaster delayed their letters, the King took the appointment into his own hands. It might be fairly presumed, even in the absence of direct evidence, that the postboy who carried despatches or accompanied the traveller during a stage of his journey to take back the post-horse, would be induced now and then to carry a private letter, so that in the course of years a usage profitable to all parties would grow up, which would engraft a letter post (of a rude kind, perhaps) on a system which the law intended only for despatches and for travellers. The hypothesis is confirmed by history, and this practice eventually became so extensive as to attract the attention of the Government. The years 1635 and 1637 witnessed the issue by Charles I. of his famous proclamation establishing our post-office on its present foundation, and directing that it should extend to Scotland and Ireland. The merit of this enterprise would seem to belong to Thomas Witherings, who was appointed first Inland Postmaster-General, he being already one of the masters of the foreign post. Soon afterwards the ever-memorable troubles of that unhappy reign broke out. The proclamations had claimed for the Crown a right of monopoly. It will create no surprise to learn that this prerogative was questioned by Parliament; nor that when the Houses became paramount over the King, they confirmed the monopoly, transferring it, however, to themselves, and closed a rival post-office which, after Parliament had contested the Kings's right, had been set on foot by the City of London. As the conflict between the Parliament and the City (no such unequal combatants in those days as they would be in the present) would call for legal knowledge on the part of the Postmaster-General, his office was united to that of Attorney-General, in the person of Mr. Prideaux. He claimed, probably with justice, the credit of having so improved and expanded the system as to make it not only self-supporting, but even to yield a profit. Taught by the success of the City enterprise, he lowered the rates of postage and increased the frequency of despatches, thus evincing that he not only apprehended, but acted upon principles which, although they have ever since received lip-homage, have too often been disregarded in practice, official men preferring immediate petty gain to large profits in the not distant future. In spite of great deficiencies in the service, the revenue of the Post-office, says Lord Macaulay, was from the first increasing.

In the year of the Restoration the net receipts were estimated at about 20,000*l*. At the close of the reign of Charles II., the net receipts were little short of 50,000*l*., gross about 70,000*l*. But the proceeds came partly from the monopoly of post-horses, which was a considerable source of profit. About the year 1683, Robert Murray, an upholsterer of London, set up a Penny Post, which delivered letters and parcels six or eight times a day in the busy and crowded streets near the Exchange, and four times a day in the outskirts of the capital, the Royal Post-office having made no provision for correspondence between one part of London and another. This undertaking he assigned to William Dockra; but as soon as it became clear that the speculation would be lucrative, the Duke of York, on whom the whole net revenue of the Post-office had been settled by his brother, complained of the Penny Post as an infraction of his monopoly, and the courts of law decided in his favour. Murray's invention was thus wrested from Dockra, and its profits went to swell the income of the Duke. The fusion of the two systems was imperfect, the letter-carriers belonging to each being still confined to their former duties, so that they would often be found in the same street, and not seldom would meet at the same door; whereas if one had handed over his letters to the other, and had then retired, the work might have been performed just as well. It would hardly obtain belief, but for the notoriety of the fact, that this waste of labour, which to the public was a waste of money constantly increasing, survived to the year 1854. So dear, from long association, had this absurdity become to official men, that although it was attacked in the report of the Commissioners of Inquiry as early as 1829, and although its abolition was an object of earnest desire with the author of Penny Postage, who included the change in his proposal when he submitted it to the nation and to Parliament, yet it was not until fourteen years after he entered upon the administration of the Post-office that he was enabled to overcome the impediments which the usage of nearly two centuries had accumulated in the way of this obvious improvement. Until 1720 the lines of postal communication had been radial from each metropolis of the three kingdoms, the number of cross-posts being comparatively few. But in that year the well-known Ralph Allen, then at the head of the Bath Post-office, made a contract with the Government to establish a cross-post between the cities of Exeter and Chester, by way of Bristol, Gloucester, and Worcester, thus connecting the West of England with the mail route to Ireland, and giving postal intercommunication with many towns of importance. His terms were—to bear himself all the cost of the service, to pay a fixed rent, and to retain the surplus. This contract was renewed and extended from time to time, so as to include other branches of road, and terminated only with his death, in 1764. Mr. Palmer (a great name in the annals of the Post-office) says the net profits of this contract to its holder amounted to 12,000*l*. a year, or, in the total, to rather more than half a million! This is the only instance of unclouded good fortune in the career of postal reformers. Eighteen years after the death of Allen appears John Palmer, proprietor and manager of the theatres of Bristol and Bath. The most obvious feature of his plans was the substitution of mail-coaches for boys on horseback, or for mail-carts, though he introduced many other improvements. He encountered much opposition, but the Minister, the younger Pitt, adopted his plans, and Mr. Palmer was employed to carry them into effect. His opponents bided their time, and two years afterwards, when his plans were yet only in partial operation, he had to encounter another struggle, and was defeated. The Minister, although he gave up the inventor, retained the invention. It had been agreed that Palmer was to have 1,500*l*. a year, and $2\frac{1}{2}$ per cent. upon all excess of revenue beyond a fixed sum. When ejected from the Post-office, not only did his salary terminate, but instead of his $2\frac{1}{2}$ per cent. he was obliged to accept a life annuity of 3,000*l*. This, even at that early date, was below the proceeds of his percentage, while the rapidly advancing revenue soon made the difference far

* Delivered before the Royal Institution.

wider. He appealed against this injustice, and eventually obtained a Parliamentary grant of 50,000*l.*; an amount, however, wholly inadequate to satisfy his claim.

To what foster-parents the young system was consigned on the loss of its father, may be gathered from certain criticisms proffered by the gentlemen of the Post-office on Palmer's proposals, even after they had had some brief and partial trial. Mr. Draper objects to mail coaches as running *too fast.* He declares that the post cannot travel with the expedition of chaises and diligences on account of business needing to be done at the Post-office in each town through which it passes — the fearful velocity which Mr. Draper deprecates rising possibly to six, or, in some cases, even to seven miles an hour. Be it remembered, however, that prior to Mr. Palmer's innovations, the average rate of the mail, including stoppages, was only three miles and a half per hour, which, in the opinion of the office, left nothing to be desired! In truth, speed appears to have been looked upon with great suspicion. Palmer had maintained that the post should outstrip all other conveyances; but the judicious Mr. Hodgson says, "I do not see why the post *should* be the swiftest conveyance. Personal conveyances, I apprehend, should be much more, and particularly with people travelling on business." Palmer found the net annual revenue of the Post-office about 150,000*l.* By the year 1814, in the face of an enhanced tariff, it had risen tenfold, namely, to 1,500,000*l.* — an augmentation chiefly attributable to the greater speed and punctuality secured by his improvements, though aided unquestionably by the national advancement in population and wealth. But thenceforward, until the epoch of Penny Postage, the impulse given to the increase of letters by the causes already pointed out, and indeed, by all others — especially by Macadam's admirable invention for bettering our roads, which enabled the mails to attain a rate, including stoppages, of ten miles an hour — proved to have become exhausted. For twenty years the number of letters passing through the Post-office remained stationary, amidst the rapid development of our manufactures and our commerce, the concentration of the national mind on the arts of peace, the consequent expansion of correspondence, and the innumerable facilities for its distribution which had been thus created and had been necessarily displayed before the slumberous eyes of the postal authorities. The augmentation of correspondence had broken through the monopoly of the Post-office, guarded although it was by high penalties, rigidly enforced. The mail coaches were outstripped by the improved stage coaches, which set the penal laws at defiance and carried an enormous number of contraband letters. But in spite of harsh laws harshly executed, of a straitened service, and of exorbitant rates, the Post-office still remained a popular and respected institution. At length, however, it discovered that it had traded too long on its reputation. Murmurs were heard among the people, and the discontented found a champion in the late Mr. Wallace, M.P. for Greenock, who frequently called the attention of the House to the preposterous rates of our postage. The desire for change grew with a steady growth.

In the year 1837 Mr. Rowland Hill, then filling the position of secretary to the Commissioners for managing the affairs of South Australia, a person scarcely known beyond the circle of his family and his friends, put forth a scheme of postal reform which, being named after its most striking feature, was called Penny Postage. He proposed the uniform rate of a penny for all letters under half an ounce, to whatever part of the United Kingdom they might be carried. Hitherto, if a letter consisted of two pieces of paper, however small, it was charged double postage. Treble letters paid treble postage; quadruple letters, and all other multiples paid according to weight, but on a scale still increasing in proportion to distance. Taking all matters into account, he struck an average, whence it appeared that by his plan the public might command for 1*d.* as much postal service as could be had on the then established rates for 9*d.* The people at large, the manufacturing and mercantile classes, the clergy — who witnessed every day the privations endured by the poor for want of a post office within their means to use — all united in loud and earnest prayers to the Legislature to confer upon them the boon which had been held up before their eyes. On the other hand, the heads of both the great parties in the State were impressed with the fiscal dangers of the proposed experiment; many believing that the project involved not merely an extinguishment of all revenue from letters, but, in addition, a ruinous subsidy to defray the expenses of the service. Not that Mr. Hill had left his plan unsupported by allegations of fact and by arguments which, in the event of the facts being sustained in proof, showed that the attractive results promised might be achieved without any ultimate diminution of the net revenue to a more serious extent than from 1,500,000*l.*, at which it then stood, to 1,200,000*l.* For a long series of years prior to 1837 the state of the Post-office had been a favourite subject of inquiry both by Royal Commissioners and Parliamentary committees, although the only very conspicuous product of these investigations was a formidable pile of blue books. To Mr. Hill, however, who had never entered a post-office in his life, these books were a mine of knowledge, enabling him to frame a set of queries, to some of which he succeeded in procuring answers. But these were neither abundant nor accurate. For instance, it was essential that he should ascertain within certain limits the number of chargeable letters passing through the British post-offices in each year. No satisfactory information on this head was the Post-office able to afford. Upon the best data within his reach, he computed the annual number at about 88½ millions; but after some time, having to a certain extent been able to correct his data, he revised his estimate, which he finally settled at 79½ millions. The Post-office estimated the number at 42 or 43 millions, then at 58 millions, next at 67 millions, and subsequently at 70 millions. But the Committee of 1838, after a most laborious and searching scrutiny, conducted with untiring zeal, and with a degree of ability which cannot be too highly appreciated, arrived at the conclusion that the real number was 77½ millions. Eventually it was admitted by the Post-office itself to amount to 76 millions, which number was finally adopted. As the scheme of Penny Postage was based on the understanding that the ultimate loss to the revenue would not exceed 300,000*l.* per annum, a tolerably accurate computation of the real number of letters was one of the problems regarding the amount of increase in correspondence required to fulfil this condition, it being self-evident that if the Post-office had been correct in its estimate of 43 millions, the required multiplication must be very much larger than if the then existing number, as was now conceded, amounted to 76 millions. The Postmaster-General contended that a twelvefold increase would be necessary, while Mr. Hill calculated that a five-fold increase would suffice. To enable the Committee to form a judgment of the sources of increase, he began by adducing evidence to prove the vast multitude of contraband letters which, if postage could be reduced to a penny, there would be no temptation to transmit through a surreptitious medium. He then proceeded to show that the number of contraband letters, great as it was, must sink into insignificance when compared with that which the high tariff prevented from being written at all. It is believed that on the institution of Penny Postage contraband transmission ceased altogether, and yet the first year added but 93 millions of letters to the 76 millions of the old system, while some portion of this 93 millions must clearly be placed to the account of letters which, but for the reduction in postage, would not have come into existence. The augmentations of subsequent years have exceeded the limits of the wildest aspirations. But Mr. Hill did not depend altogether on the effect to be produced by swelling the grand total of letters. He laid great stress on diminishing to the Post-office the expense of the service—the cost per letter, not the total expense—*that*, by the expected great increase of letters, was sure to be enhanced. This important end he proposed to attain by the combination of two expedients. One was uniformity of postage. The other the relief of the office, by the employment of stamps, from the onerous duty of collecting postage. That both these changes must be highly economical is obvious. The taxation of letters, as it was then called, meaning thereby the task of ascertaining the amount of postage for each letter, and registering it upon the letter itself, was a slow and complex process, the greater part of which uniform postage did away with. But the principal item of cost had always been the delivery of letters from house to house. Under the old system the all but universal usage was for the sender to post his letter unpaid. The inevitable consumption of time thus caused in the collection of postage would be fresh in the memory of a large portion of the audience. Neither of the two branches of postal service thus cheapened presented any obstacle to the application of the principle of uniformity; but the third, namely, the journey which the letter made from the office of reception to that of destination, would appear at first sight of necessity to demand different rates of remuneration. No one was prepared to believe that the transit of a letter from St. Martin's-le-Grand to Barnet, the first stage on the road to Edinburgh, would cost practically the same as the whole journey, and yet Mr. Hill found, on laborious investigation, that such was the fact — the sum for the whole journey only amounting to one-ninth of a farthing! Thus, it is clear that strict justice, to say nothing of convenience to the Post-office, which means economy, is more closely approached by making no variation of charge in respect of greater or smaller distances of conveyance than could be attained by acting on any differential scale imaginable, unless, indeed, we had a coinage descending far below farthings. By the result of this investigation, which I think I am justified in calling a discovery, all objections to adopting the principle of uniformity were fully answered, and Mr. Hill's case was complete. The Committee reported in his favour; the project was embodied in a Bill; passed the Legislature the next session, and, at the commencement of the year 1840, was carried into operation.

And here time warns me to break off my narrative. I will conclude with a brief comparison of postal affairs as they stood at the publication of Mr. Rowland Hill's plan, with their present state; premising that the results which I have now to exhibit could not have been obtained without hearty and intelligent co-operation on the part of many gentlemen in the Post-office, who in the discharge of their respective duties have laboured with fidelity and devotion to promote the new system to the best of their ability. I cannot bring myself to pass their exertions by in utter silence, although I have no space for a more explicit notification of their services. As late as the year 1838, of the 2,100 districts of the registrars of births, deaths, and marriages in England and Wales, about 400, then containing 1,500,000 inhabitants, were destitute of a single post-office. The average extent of each district was nearly 20 square miles. Several of these postal deserts were considerably larger than the county of Middlesex! The average population of the chief place of each district was 1,400, and its average distance from the nearest post-office between four and five miles. Yet the ramifications of our postal system pervaded England far more thoroughly than they did the remaining divisions of the United Kingdom. Many other English and Welsh districts, though possessing post-offices, were yet so scantily supplied with them in proportion to their area, that in all probability 4,000,000 of the population of England and Wales, amounting at that date to one-quarter of the whole, must be held to have been destitute of postal accommodation. The great extent of the deficiency might be also gathered from the single fact that, while England and Wales contain about 11,000 parishes, the total number of their post-offices of all descriptions was only 3,000. At the present day the comparison stands thus:—The number in England and Wales has increased to 11,000, making it scarcely possible that any one of the registrars'

districts should now remain unsupplied with a post-office. The offices in Scotland and Ireland have also received considerable augmentation, the number in the United Kingdom having risen from 4,518 to 14,358. In 1838 Mr. Hill suggested the institution of day mails, to facilitate the despatch of letters. Now a mail by day as well as by night is despatched to most of the towns in England and Ireland. A large number have the advantage of two day mails, and some have even three or more. In the metropolis, under the old system, there were but six deliveries *per diem*. There are now eleven. Several of the suburban districts have six deliveries a day. The measure which rendered these improvements practicable was the division of the metropolis into ten postal districts. It came into partial operation in 1856, and is now almost complete. Each of these districts is treated as a separate post town. This arrangement has been followed by a vast and rapid increase of letters posted and delivered within the London district. During the five years preceding 1856, the average annual advance in the number of metropolitan letters was only 3¾ per cent. By 1858 it had risen to 12 per cent. These letters far exceed the total number from all sources—home or foreign—delivered throughout the whole island of Great Britain (London included) in 1839. They amount to 68 millions, being only 8 millions less than the grand total of the United Kingdom for that year. Subdividing London has also effected a considerable acceleration in the first delivery of each day. Postage to and from the colonies and foreign parts has been much lowered, while the transit has been greatly quickened. In 1839 the number of newspapers delivered in the United Kingdom was about 44½ millions. At that date every copy, by law, bore a stamp, which, however, had the advantage of franking it when sent by post. This privilege furnished a strong motive to proprietors and newsmen to distribute their impressions through that channel; whereas at present, if copies are sent by any other means than through the post, no expense is incurred in stamps. Nevertheless, the number despatched through the Post-office last year reached 72½ millions.

The privilege of sending books and works of art by post at a reasonable charge is one of Mr. Hill's improvements. Medicines, watches, patterns, botanical specimens, seeds, and many other articles now pass largely through the office, to the convenience of all, but more especially of residents in the country: for it is not undervaluing the great benefits we have derived from the multiplication of railways to remark that they do not, and probably never can without the aid of the Post-office, distribute parcels even to all our towns, much less to our villages and single houses; whereas the proportion of letters and other posted packets delivered by the letter-carriers at the houses of those to whom they are addressed is now probably not less than 95 per cent. of the total number despatched. Of late years the rapid development of the book-post, which dates from 1848, has been remarkable. In 1854 the number of such packets was only 750,000, yet last year it had swollen to twelve millions.

An important branch of the service, largely developed since the institution of Penny Postage, is the system of money-orders. In 1839, the total number issued for the United Kingdom was 188,921, and the amount of money 313,124*l.* In 1861, the number reached 7,580,455, and the amount was 14,616,348*l.* And during that interval, although the price of money-orders has been reduced to one-half, the growth of the system has been accompanied by a change most advantageous to the department. In the first years the service entailed a loss, which for 1847 amounted to 10,000*l.* In 1860, it brought a profit of 28,000*l.* Intercommunication of every kind told upon the increase of letters, and, no doubt, the last addition to the benefits conferred by the Post-office, namely, its Savings-banks, now rapidly spreading over the land, will be followed by similar consequences.

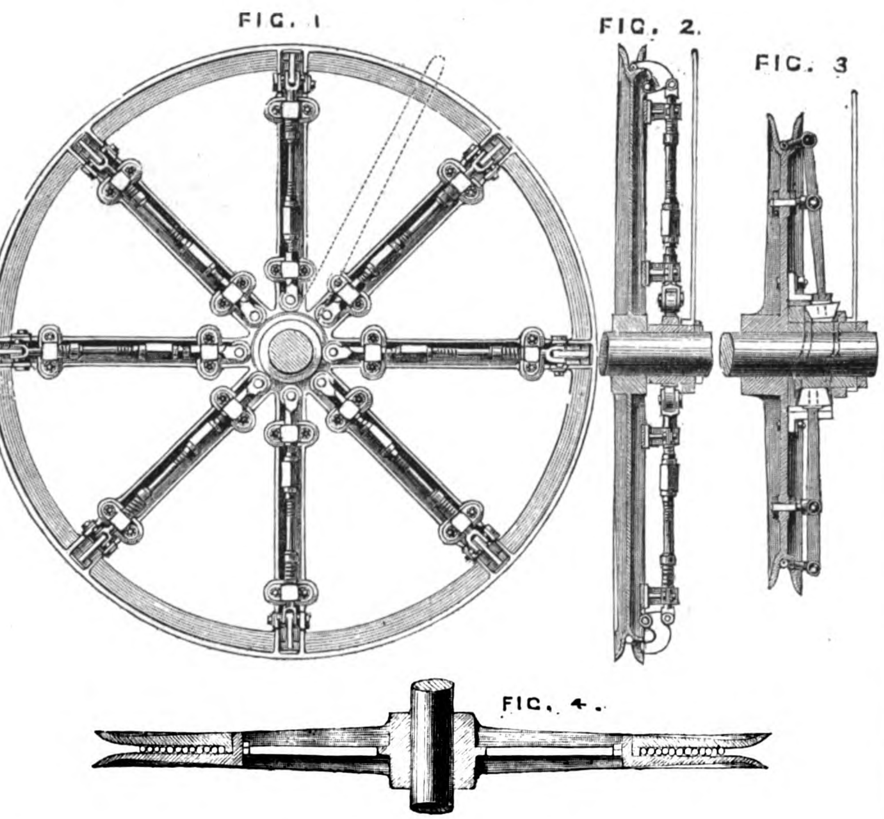
From the various causes thus co-operating to the increase of letters, I pass to effects. The number of chargeable letters delivered from the British offices in the last complete year before the reduction of postage was, as I have said, taken at 76 millions. The number in 1861 had risen to the stupendous amount of 593 millions, being nearly an eightfold multiplication of the former number. Let us study the proportion of letters to population at the two extremes. In 1839 it stood thus:—In England and Wales four letters per annum to each individual, in Ireland one, in Scotland three, being an average of three to each person in the United Kingdom. In 1861 it had grown in England and Wales to twenty-four per head, in Ireland to nine, in Scotland to nineteen, being an average of twenty per head for the United Kingdom. This enormous increase might be placed in still another light. The total weight of letters, exclusive of newspapers and other matter, during the year 1839, was 758 tons. In 1861 it had risen to 4,300 tons. The increase of the average daily mileage of the mails is very striking. It was estimated that in 1839 it did not exceed 54,000 miles per diem, whereas, in 1861, it had risen to 149,000, being six times the circumference of the globe. The staff of officers of all ranks and both sexes constantly employed in the labours of the Post-office was, in 1839, by rough estimate, about 8,000. In 1861 it was, by exact enumeration, 25,473. In addition to this force, many persons are engaged for a portion of their time. The gross revenue in 1838 was 2,346,278*l.*; in 1861, upwards of three millions and a half. Hence it appears that, notwithstanding the wonderful reduction, whereby the public now obtains far more of the article postage, for the same price, than it did formerly, yet that its expenditure in postage exceeds by more than one-half the amount so spent under the old exorbitant rates. The net revenue for the last year exceeds 1,500,000*l.*, so that, as regards both gross and net revenue, the facts have gone beyond Mr. Hill's original estimate. Nor is the promise for the future less brilliant than the experience of the past. Correspondence is still advancing by rapid strides. One feature in this vast accession cannot but give rise to sanguine expectations. Whatever the vicissitudes in our harvests — whatever the fluctuations of our commerce — whether we are in the enjoyment of peace or suffer the privations of war — each revolving year adds to the mass of our correspondence. The tide of our letters, like that from the Pontic to the Propontic Sea, knows no ebb. 1861, though by no means a year of unclouded prosperity, added an influx of twenty-nine millions — an addition even beyond the average of former years. Such, then, is the success of Penny Postage, and such are its prospects. Still, though no peril can be discerned, the instinctive feelings of mankind and the teachings of history warn us always to be prepared, if not for reverses, yet for some interruption in this course of unexampled prosperity. That, should checks occur, they will be transient and casual, we may reasonably expect, since correspondence does not flourish or fade with the changes of manners or fashions. Its growth is governed by causes not peculiar to any one country, but common to all. This is demonstrated by the rapid spread of the new system throughout the civilised world. One source of danger is dried up. The Post-office no longer assumes to be perfect, and its conductors have renounced their claims to infallibility. Suggested improvements, if they sustain the necessary test of rigid scrutiny, are welcomed, and not, as of old, frowned away. The department acts under the conviction that to thrive it must keep ahead of rivals — that it must discard the confidence heretofore placed in legal prohibitions, and seek continuance of success only by deserving it.

The iron trade continues much in the same state as last week. There are some orders in the district from America. Plates of small dimensions and sheets are in fair request, but for angle iron and rounds the demand is not at all brisk. Good samples of pig iron are fetching better prices than they were, but the rates are far from being remunerative. The demand for large coal still rules dull, but the price, with some few exceptions, remains unaltered. Lumps and fine slack form an exception. Ironstone, the produce of the district, has an upward tendency, and labour is more in request.

ART IN COPPER.—The malleable quality of copper and its adaptability to the purposes of art have seldom been more fully demonstrated than by Mr. Thomas Phillips, of Snow Hill, in a work of very high merit, of which the spirited design is only equalled by the ambition displayed in its execution. Of all forms of animal life, none have presented more difficulties, and none have been attempted with less success by workers in stone or metal, than the forms and attitudes of birds, whether in a state of motion or repose. This defect, due to the materials used, more than to the deficiencies of the artist, has been boldly grappled with, and successfully overcome by Mr. T. Phillips, senior. His figure of a "golden eagle" is the first attempt made to render feather for feather in either metal or stone. The eagle, which is of the natural size, stands on the summit of a rugged and precipitous rock, in a bold and threatening attitude. With wings outspread ready for a dash at his quarry, or to withstand a human foe, the bird, with one claw advanced, firmly grasps with his talons the rocky ledge, while, with head protruding, and open beak, he absolutely seems to scream warning and defiance. The keen eye peering from under the shadowing ridge of the skull, the rising feathers of the crest, the swell and ruffling of the muscular neck, form a picture of savage anger as true to nature as it is admirably conceived and executed. The whole figure is instinct with life, and has more the appearance of a real bird electrotyped by some miracle than aught else to which it can be compared. Every one of the minute feathers which cluster round the neck, the fine hair-like down which runs from the beak to the eye, the soft cushion of plumage at the junction of the wings and body, are here separate, and can be each separately raised by the finger. The half hairy, half feathery legs of the bird are wonderful in the fineness of the down which overspreads them. The most extraordinary triumph of Mr. Phillips's skill, however, is shown in the extremely minute feathers which cover the frame of the pinions and which conceal the fastenings of the large feathers forming the tips of the wings. It would be impossible to overrate this portion of the work, so numerous and so thick are the feathers, and so soft and deep is the effect produced. The rock which forms the eagle's eyrie, a fine mass of tin and antimony in combination, is of bold workmanship, and forms a pleasing contrast to the somewhat dusky colour of the plumage. Nothing can be more happy than the colouring of the figure of the bird. The metallic lustre of feathers, so difficult to imitate in painting, is here rendered with great felicity. Equally good also is the horn-like appearance given to the beak and talons, while the yellow and wrinkled scales of the feet are life-like. The mode of colouring which Mr. Phillips has employed is a secret of his own, and was discovered by him in the course of executing this figure. It is an improvement on the old system, inasmuch as it supersedes the aid of a battery by a new process of what may be called cold electrotyping. Its chief advantage over the ordinary method consists in the variety of colouring on the same surface which it allows, and its superior economy. For six years Mr. Phillips has been employed in bringing this work of art to its present condition. More than 10,000 feathers, formed from ordinary copper-plate, all made by hand, some of which had to pass twenty-six or twenty-seven times under the hammer and graver, were necessary for the plumage alone, and show the unwearied patience and industry employed on what has evidently been a labour of love. Mr. Phillips, we understand, proposes shortly to allow the public to judge of its merits.—*Times*.

At a recent meeting of the Austrian Society of Engineers, Mons. Bender, Chief Inspector, gave an account of an apparatus invented by Mons. Schan, to prevent incrustations in boilers. It consists of a closed cylinder placed high up, and attached to the boiler by a short pipe. In this cylinder the feed-water is sprayed by a rosette, which reduces it to minute drops, so that the steam instantly heats it to the boiling point, before it reaches the boiler. This increase of temperature precipitates the solid matters which are deposited in the cylinder. The advantages of this have been established by experiments on a large scale: a locomotive fitted with this apparatus has run 5,500 miles in several trips; it has deposited 267lbs.=0·014 of matter, soft like soap, while the boiler remained clean. The result was the more remarkable, because at the beginning of the experiment it was covered with a solid crust 5-16 in. thick, which had completely disappeared during the travels. Mons. Egerth, who presided, observed that when the feed-water was returned to the tender after being much heated, it caused considerable deposit, while the boiler remained nearly clean.

BURROWS AND DOUGAN'S PATENT WINDING DRUMS.



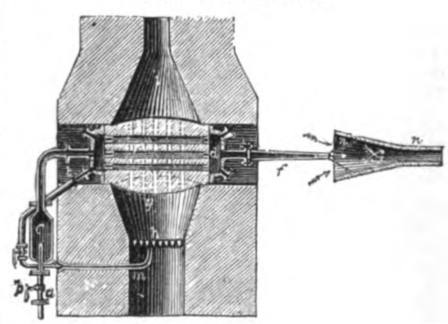
Messrs. Burrows, of Wigan, and Joseph Dougan, of Haigh, Lancashire, engineers, have recently patented an invention for improvements in winding or driving drums or pulleys. The first part of this invention consists in the application of power or pressure to some part or parts of the rope, band, or chain during the time in which such parts or portions of the rope remain in contact with the drum or pulley, by which means an increased amount of adhesion is obtained, and a correspondingly greater power for driving machinery, drawing or lifting weights, and similar purposes. At a number of points in the circumference of the winding drum, or driving drum, or pulley, we attach clips or holding pieces, which are caused to press upon the rope, band, or chain whilst it is in contact with the pulley, and to force it against the sides or bottom of the groove in the pulley. The clips turn upon centres so as to be withdrawn from the rope or chain at or near the point at which it leaves the drum or pulley, and are attached to or acted upon by rods radiating from the centre of the pulley, and having antifriction rollers at their inner extremities, which are in contact with the circumference of a cam placed on the drum shaft, a portion of which cam corresponding to the portion of the pulley which is in contact with the rope, is formed to a greater radius than the rest, so that (the cam being held from revolving with the pulley) as each antifriction roller arrives at the raised portion of the cam, the rod to which it is attached is forced outwards, and acting upon the clip causes it to press upon the rope as long as the roller continues to run on the raised portion of the cam, being released by a small spring or other suitable apparatus, when the roller is clear of the raised part of the cam; or the clips may be attached to the outer extremities of levers radiating from the centre of the pulley, and having antifraction rollers at their inner ends acted upon by a suitable cam, for the purpose of closing the holding pieces on to the rope at the proper time, and by a corresponding cam reversed for the purpose of releasing the clips.

The second part of this invention applies to winding drums or pulleys for round ropes in particular, employed for winding coals, &c., from mines or other similar purposes, and is designed more especially for the purpose of compensating in a higher degree than has been usual hitherto with round ropes for the extreme weight of the rope or ropes, thereby diminishing the extreme load or pressure upon the engine, or otherwise enabling the same engine to do more duty with the same pressure or their equivalents. This improvement consists in arranging the sides or plains of winding drums, sheaves, or pulleys parallel as near as may be to each other, leaving a width or space between the insides of the planes of each drum, sheave, or pulley equal to or only a little in excess of the diameter of the rope to be used, so that when the rope is attached to the drum and the drum is caused to rotate, each consecutive coil will be laid or wound upon the preceding coil, and so on in succession, instead of as is usual coiling upon a drum side by side, or to the extent of a few laps only in depth. By this arrangement the practical diameter or leverage of the drum is increased as the rope is wound on, thus wholly or partially equalising the power required for raising such length of rope and load throughout the process of winding.

DAGUZAN'S IMPROVED METHOD OF PAVING ROADS.

Monsieur V. L. Daguzan, of Paris, proposes to pave roadways in the manner shown above, which consists in the superposition of two roads or ways, one underneath composed of trenches or gutters made of beton, and covered with bitumen, or other water-resisting composition, serving to conduct the water and detritus into the drains, and sufficiently strong to support the upper way for the circulation of horses, carriages, and foot passengers. The upper road or way is composed of slabs or flags placed horizontally side by side, with spaces left at certain distances between them for the passage through them of water, detritus, and other matters into the drains. These slabs or flags may be of granite, or other stone or substance sufficiently strong and suitable for the purpose. Slabs made of cast-iron are preferred, having cellular openings or spaces, in which are applied and fixed by bitumen or other suitable substance, blocks of sandstone, porphyry, granite, or wood, impregnated or not with preservative substances. The distance between the two ways may vary: thus, the upper road or way may be close to and be supported on parts of the lower road or way, provided with canals or conduits for running off the waters, detritus, and other matters driven into the drains by flushing or by cleaning tools; or the distance between the two roads or ways may be several yards, in which case the slabs or flags forming the upper way are supported by walls, posts, columns, arcades, vaults, or other suitable supports, so that the cleaning may be easily effected, and at convenient times underneath the upper way. With this latter construction drains may be placed in the centre of the lower road or way, which will render the cleaning easy, and permit of placing under the upper way water and gas pipes, and telegraphic wires, which may be placed between the two ways, so that their keeping in order and repairing may be performed without stopping the circulation, or very rarely.

BROOMAN'S IMPROVEMENTS IN SUPER-HEATING STEAM.



The accompanying engraving illustrates, in vertical section, a furnace and vessel for superheating steam, which vessel the inventor, M. Testud de Beauregard, of Paris, terms an "Aërhydric Blower."

The invention relates to the generation and employment of dry and superheated steam at a temperature of about 390° Fahrenheit, or of a gas fixed or not, the pressure of which shall be equal to what may be necessary for the particular application for which it is to be used. This steam or gas is caused to escape from an orifice by virtue of its compression into another orifice, calculated according to the quantity of air required in a given time. The mixture of steam or gas and air is projected upon ignited combustible matter. There is then produced the phenomenon of double decomposition; the air yields its oxygen to the combustible matter to assist its combustion, and the steam already divided will become decomposed into oxygen and hydrogen, so as to produce the highest combustion. This blower is applicable to various industrial uses.

1st. It is an advantageous and economical substitute for the blowers for forge fires, blast furnaces, and other uses as at present made.

2nd. When used with steam generators, fire bars may be dispensed with; no smoke will issue and a great development of caloric will result.

3rd. For locomotives the blower acts either for drawing in air, and allows of a measurable quantity according to requirement or as a supply of combustible; the steam transformed into hydrogen and oxygen aids as an economical and powerful caloric agent.

4th. By its employment pure and carburetted hydrogen gas may be obtained, which may be used as a heating or as a reducing agent.

This method of superheating steam or gases to a high temperature may be employed in the reduction of metals, in the desulphuration of ores and coke, in the firing of china and earthenwares and glass, in the baking of bricks and plaster, and in the burning of lime, in carbonisation, distillation, and otherwise.

a is a pipe provided with a tap *b* for conveying the superheated steam or gas into a chamber *c*, where the steam is dried or deprived of its watery portion. The steam leaves the chamber *c* for the superheater, which is made of cast iron or fire clay, and consists of a superheating vessel *d* placed in and across a furnace; horizontal steam tubes *e, e*, are placed in this vessel through which the steam circulates, is superheated, and escapes by the pipe *f*. *g, g*, are vertical tubes, indicated by dotted lines in the superheater to allow of the gases and products of combustion passing through them from the grate *a* to the chimney *i*; *l* is a pipe, one end of which is in connection with the superheating vessel *d*, and the other with a passage *m*, whereby steam is led under the grate before or after being superheated, to act as a blower to the furnace and superheater. Steam to be superheated enters through the pipe *a*, furnished with the cock *b*, into the drying chamber *c*, from which a pipe conducts it into the superheating vessel *d*, in traversing the horizontal tubes *e, e*, in which it becomes superheated; it issues from the superheating vessel into an outlet pipe *f*, the nozzle of which enters a tube *n*, in the side of a blast furnace or kiln, the mouth of which is funnel-shaped. The section of the outlet pipe *f* is calculated according to the quantity required in a unit of time; its nozzle should be removed so much farther from the mouth of the funnel-shaped tube *n* as the pressure is to be increased. The mouth of the funnel is also calculated according to the quantity of air to be introduced concurrently with the steam or gas in the same unit of time. The smallest opening is a section which will allow of the addition of the quantities of air and of steam or gas which are to be projected under the pressure necessary to the combustion to be obtained. There are cups in the superheating vessel containing metals or alloys of different degrees of fusibility, which answer as pyrometers, and are for the purpose of enabling the person in charge to regulate the fire. A pipe furnished with a cock is carried from the superheating vessel and enters another, the outlet from which is under the fire bars. Thus a blower is provided to the apparatus itself.

NEW MODE OF MAP ENGRAVING.

At a recent meeting of the Franklin Institute, Philadelphia, Samuel Sartain, Esq., engraver, of that city, exhibited an impression of a large map, devised and executed on a new and effective plan by Col. Baron Egloffstein, U.S.A. It illustrates the labours of the U. S. expedition for exploring the *Colorado River of the West* and surrounding country in New Mexico.

Baron Egloffstein, the topographer of the expedition, conceived the idea of endeavouring to give his map the appearance of a small plaster model of the country; and to do this he treats the forms of nature as an artist would draw any form before him — that is, by giving the real light and shade that would be developed by light falling on the model at a suitable angle. The mountains have their shadow-side engraved in the usual manner by "*hachures*," but the light-side is only slightly tinted in parts to develop detail of form, and is brilliantly relieved by a tint spreading over the level plain like an Indian-ink wash; this tint is made of several grades of strength, intended to show the *relative altitude* of the several plateaus over which it is spread, the lowest or alluvial lands having the darkest tint, and the loftiest table-lands having the most delicate.

The result in the present map is bold and striking, showing at a glance the nature of the whole country, enabling anyone to perceive the character, prominence, and relation of the different parts. This region of country has features unsurpassed in their kind for grandeur and sublimity; the Colorado of the West flows for 300 miles of its course through Cañons whose sides often rise perpendicularly from 3,000 to 6,000 feet in height; the "Great Cañon of the Colorado" is the most magnificent gorge as well as the grandest geological section of which we have any knowledge. For this reason Colonel Egloffstein's system of mapping has unquestionable advantages; its freedom from conventionality and its truth to nature give it a power, unattainable by the old system, of representing forms so that they are intelligible to every eye.

The French at one time used a system of topography similar to this; it had light-sides and shade-sides to the mountains, but they did not tint the level plain, on which so much of the character and beauty of this style depends. The tint on the steel plate shown is machine-ruled (nearly 200 lines to the inch), and graded to the requisite strength by acids, giving by its fineness the appearance of delicate India-ink tints: this portion of the work was executed by Mr. Samuel Sartain, and excels as a specimen of this method of engraving.

Colonel Egloffstein deserves the thanks of the *public* for enabling them to read some of the results of scientific labours with an *ease* that was before only possible to the professional topographer, and at perhaps less expense than by the old system.

OVERWORKED RAILWAY ENGINE-DRIVERS.

On Tuesday last, in the House of Commons, Mr. Cobbett called attention to the petition of engine-drivers and firemen, working on several lines of railway, complaining of the excessive number of the hours during which they worked continually, also to other petitions on the same subject, and moved "That a committee be appointed to enquire into the matter of the said petitions." He said that the grievance complained of affected a large body of working men, and also the public. Some eighteen months ago he was applied to by a number of engine-drivers and firemen on the Great Western, the Lancashire and Yorkshire, and four or five other railways, to bring their case before Parliament. They represented that they were kept at work for so many hours continuously that their health was injured, and the lives of passengers placed in jeopardy. The averages of their hours on certain railways were respectively 14, 16½, 15, 16, 14, and 15 in the 24 hours. The greatest number of hours at which men worked consecutively were 20, 25, 23, 23, 26, 28, and 24, on different railways respectively. The petition of the engine-drivers and firemen was signed by 700 men. The body consisted of many thousands, who were respectable, and had great influence. Those who complained said that their hours were unnecessarily long, and, with proper management, might be shortened. It was only on seven lines of railway that complaints were made. On others, including the Great Northern, there was no such grievance. When first applied to he recommended these men to appeal to their directors, and then to the Board of Trade. They had done so, and had failed to obtain redress, and therefore he brought the subject before the House. In one of the many cases which had been laid before him, a man had worked as many as fifty-six hours in three days — pretty nearly fifty-six consecutive hours — and in another case a man who had worked nineteen and three quarter hours was obliged to resume duty after a rest of two and a quarter hours. An article in the *Quarterly Review* traced a collision on one of the Scotch lines to the exhaustion from over work of the men in charge of a train. One man had told him that he frequently slept for miles on his engine, and when he awoke he could tell where he was only from some peculiarity in some posts by the side of the line. Such things placed the public, when travelling by railway, in considerable peril. In addition to the petition of the engine-drivers and firemen, he had presented thirteen petitions from the inhabitants of towns on the railways in question, signed by mayors, town-councillors, magistrates, clergymen, and merchants, who stated that they knew that the engine-drivers on the lines on which they travelled were overworked, and that their own lives were jeopardised. They therefore prayed the House to pass some measure upon the subject. He now made his motion as a matter of form; and if a committee were not granted, owing to the lateness of the session, and no other result followed, he would, in a future session, do something more than merely call attention to the subject.

Mr. Gibson said that it was true that a deputation of engine-drivers had attended at the Board of Trade, representing that they were suffering under a system of very long hours of labour. It did not appear, however, that the whole body, as a class, agreed to the necessity of Parliamentary interference between themselves and their employers. They admitted that those who were moving in this matter formed only a small portion of the engine-drivers. No doubt there were particular cases of persons working long hours; and, if such a practice were general upon the railways of the United Kingdom, the engine-drivers would be unable to exercise the vigilance necessary for the safety of the public. But, as a matter of fact, he was informed by the inspectors of the Board of Trade that accidents had very rarely occurred through the long hours of work by the engine-drivers. Besides, it appeared to him that it would be altogether a new principle to interfere in such a case. Parliament had protected women, children, and young persons in factories; but it had never yet regulated the labours of adult men. It would be much wiser to leave the engine-drivers to settle their own affairs with their masters, than for the Legislature to take them under its special protection, especially as they were a most intelligent class of persons, quite capable of taking care of themselves. Theirs was highly skilled labour; they were paid extra for extra hours; and it was of their own will if they worked long hours. Under these circumstances he hoped his hon. friend would allow the matter to rest where it was.

Mr. Hadfield asked for the names of the railways which were stated to overwork their engine-drivers. Mr. Cobbett replied the Blythe and Tyne, the Lancashire and Yorkshire, the London and North Western, Sheffield and Lincolnshire, Midland, and South Yorkshire. The motion was then withdrawn.

An important undertaking in connection with India is announced in the "Oriental Canal and Irrigation Company." The general objects are the construction and maintenance of various works of water transit, in order to improve the navigation of rivers, and to adapt them to irrigation and other profitable purposes. But the particular work proposed to be immediately undertaken is the construction of a navigable canal to connect the Indus at Jerruck with Kurrachee. This will save about eighty miles in distance, much expense, and a great deal of time in the conveyance of goods between Scinde and Kurrachee; it will further irrigate and fertilise an immense district suited to the production of the best cotton, as well as sugar and indigo; and lastly, it will be the means of supplying the entire community of Kurrachee with fresh water. All are sources of profit. These and other works will be complete in themselves, and thus each successive undertaking will add to the usefulness of the Company. The first capital is to be 250,000*l.* in 10*l.* shares, but it is ultimately intended to increase it to 500,000*l.* The chairman of the company is Colonel Grimes, and the consulting engineer, Colonel J. F. Smith, late of the Madras Engineers.

WALKER'S PATENT FLOATING BATTERY.

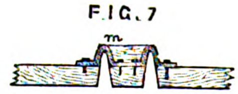

FIG. 4

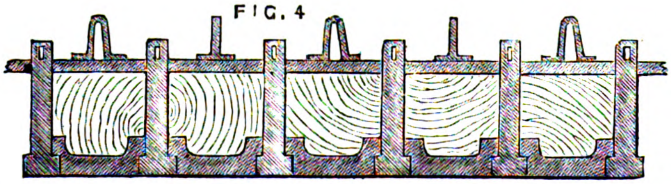


[TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR, — I have sent you a few plain sketches of a floating battery which I proposed to Lord Palmerston ten months ago. Nearly all our principal rivers have no protection whatever. Neither Glasgow nor Liverpool has anything in the shape of security from being shelled, should any hostile vessel think it desirable to do so. Fixed forts, no doubt, are very well, if you could only get those obstinate people with their ships, who mean mischief, to come near enough to be shot at; but steam has altered the whole aspect of attack and defence, and therefore we must have a number of forts that can be concentrated in a few hours to meet them at any point wherever they may come or go.

Fig. 1 shows the deck of a floating battery with tower arranged for five guns: this size is intended for great speed as well as great shot power; for protecting harbours on rivers the same kind of vessel is arranged for ten or twelve guns. As the tower is turned round, each gun may be brought to bear rapidly on the same point of any vessel trying to pass; to have to reload and fire the same gun, the enemy would be out of reach. Shot, to be really effective on plated vessels, must be point blank, and if ten shots can be made to hit the same place, it will be more effective still: in this way two good things are gained, while the tower guns are striking one point, it is turning a new face to the enemy. The dotted lines P P show the mode of keeping the head of the vessel at right angles to any enemy that may approach, and can be worked by man or steam power; it also enables a vessel to be manœuvred when at anchor. *m m* shows the mode of covering the deck and top of tower shot-proof, and at the same time giving ample ventilation.

Fig. 2 shows the elevation of the same vessel with armour plates, bulwarks, tower, &c. S is a shot-proof passage from wheel to tower.

Fig. 3 shows a section of the same vessel with tower placed in water for the purpose of raising or lowering as the gunner may require, which also enables the man to turn it easily round. The defence part of this vessel is entirely outside, to give stability when firing, and is 4 feet below the water line, and 3 feet above the surface of the deck. The standards for bulwarks drop into the bridge irons, *b*, riveted inside of the skin, so that the whole can be cleared away in a few minutes. A 5 feet opening, *e e*, is left on each side of the tower and side of the ship for a passage to and fro.

Figs. 4 and 5 show the form and mode of fastening the armour plates. The great object of this plan is to make the joints the strongest part of the plate. The plates being narrow, the middle can be easily strengthened and made secure, and, being all exactly alike, they can be easily repaired.

Fig. 6 shows the mode of covering the iron hull with timber and coppering it in the usual way; 4-inch double tee irons are riveted all round the bottom to the single tee irons inside of vessel; at

the top of every other double tee iron the flange is cut away 9 inches down and close to the web; then by shaping pieces of timber to a mould, they are put in at this opening and driven down till the whole space is covered. In this way the vessel is strengthened without bolts; felt may then be put on and coppered over. There are several other points of considerable value which could be mentioned, but I am afraid that even this will take up too much of your valuable space; but still, anything that will give us greater security than fixed forts, I am sure will claim your kind attention.

J. Walker.

25 City Road.

THOMPSON AND MAWSON'S RAILWAY APPARATUS FOR COMMUNICATING BETWEEN GUARD AND DRIVER.

Provisional protection has just been granted to Messrs. Thompson and Mawson, of Bolton-le-Moors, for "Improvements in railway apparatuses for communicating between guard and driver, and for coupling and uncoupling the carriages, parts of which apparatuses are applicable to connecting pipes and tubes," which they describe as follows:

Our invention for improvements in apparatuses for communicating between guard and driver consists of the arrangements hereafter described. We carry a pipe or tube through every carriage, and form the connections between every two carriages by means of two trumpet-mouthed tubes pressed into contact with each other by means of coiled or other springs, and free to recede within the tubes in the carriages for a certain distance; or we form our connection by means of a flexible pipe, by preference of indiarubber; one end of the pipe is fixed to the end of the tube running through the carriage, while the other end is fixed to a bell or other shaped mouth, the lips or edges of which have connected to them guide-rods free to slide in and out of the carriage, and kept extended by coiled or other suitable springs. This flexible spring-pipe coupling is applicable to pipes for conveying liquids and fluids generally.

When required to increase the intensity of the sound produced by the guard in communicating through the tube with the driver, or *vice versâ*, we place a valve near the mouthpiece, and in front of that valve introduce a bell-mouthed curved tube, open outside the carriage for the purpose of catching the wind, and of driving forward the sound made after the valve is opened.

For coupling carriages, our invention consists of two fixed hooks and of two movable ones. One fixed hook and one movable hook are fitted to each carriage, to a boss placed on the end of a bar capable of being protruded from and drawn towards the carriage. The movable hooks are pinned to the bosses on the bars, and have springs fitted to them, to cause them to assume constantly a position parallel to the rails; to each of the bosses a lever is fitted, and also a weight. The coupling is effected by the carriages being brought together, when the spring-hooks will become engaged in the fixed hooks. To uncouple, turn the boss by means of the lever, when two of the hooks on one boss will be turned and freed from one another; a weight is employed for bringing back the hooks into position, when the lever is let go.

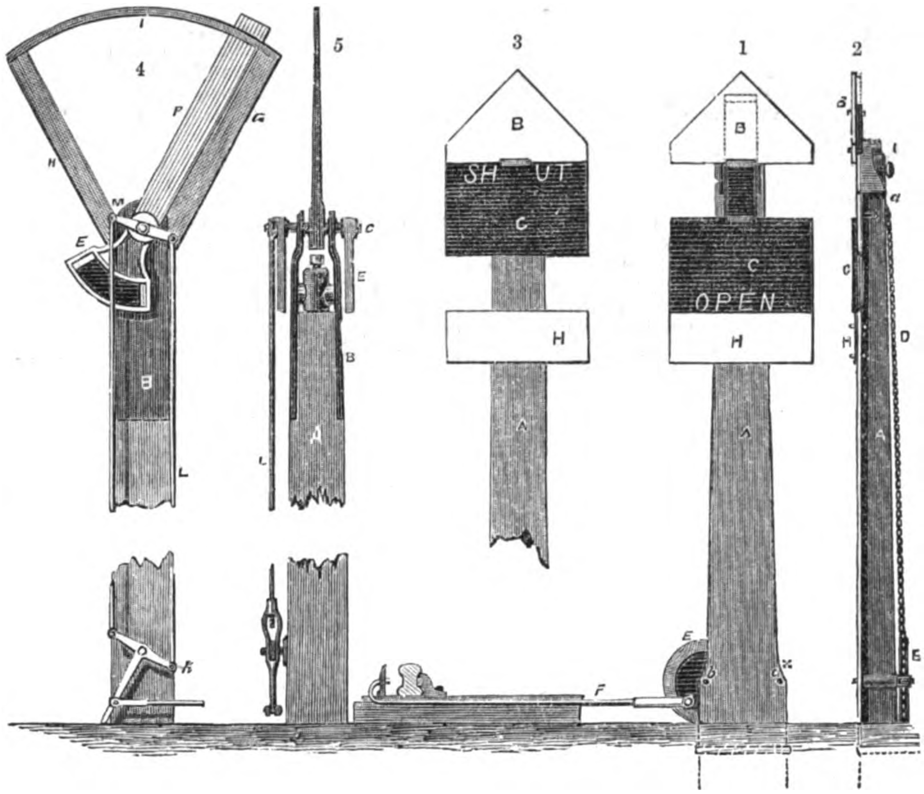
Another of our coupling apparatuses consists of an adjustable anchor-headed hook connected to each of the carriages to be coupled. First, a bar, with screw or other means of shortening and lengthening the coupling, is fitted to the carriage; the bar terminates at its outer end in a bow. Through the ends of the bow a spindle is passed; this spindle carries a roller or drum, to which a bar carrying an anchor or double hook is fastened; arms extend towards the centre of the bow from the roller, and carry a cross head through a collar, in which an upright rod is passed; on the bottom of this rod is a weight, free to be moved up and down by means of a nut. The weight forms a counterpoise to the hook and hook-bar, and, by raising or lowering the weight, the inclination of the hook and bar is regulated, and this for the purpose of suiting carriages of different heights. A lever handle is connected to the weight rods. Coupling is effected upon the carriages being brought together by one anchor hook, the heads of which are conical, sliding over and becoming engaged in the other. The uncoupling is effected by one of the hooks being turned laterally through the lever handle.

Another of our coupling apparatuses consists of two hooks movable upon a centre. One hook is connected to the end of one coupling bar, and a corresponding hook to the other. When the hooks come in contact, the ends play, give way, and the hooks pass each other; springs draw them into the former position, and the hooks, meeting in the contrary direction, become engaged.

NEW IRON-PLATED FEDERALIST SHIPS.

The last accounts which have come to hand from New York state that the twelve new iron-clad vessels which have recently been ordered to be constructed, are to be of a more formidable character than any now afloat in any country. Captain Ericsson has contracted with the Government to build six new Monitors. The plan will be the same as of that vessel, but some new ones will be about 300 feet in length, while the Monitor is only 170 feet long. Each will be 1805 tons burden, 1450 tons displacement, and 11 feet draught. They will be armed with two 15-inch guns. Several deficiencies in the Monitor will be rectified in these batteries—the pilot-house being placed on the revolving turret, and ventilations passing the roof of the latter instead of through the deck. The turrets are to be 21 feet in diameter, and 11 inches thick. The speed is to be ten miles an hour. Four of these vessels are to be ready by the 1st proximo, and two by the 1st September; 2,800 men are at work upon these six vessels, and it is fully anticipated that they will be completed by the stipulated time. A new sort of gunboat is also being built, which will be entirely of iron, having no woodwork whatever in its frames or sides. Its length will be 165 feet, breadth of beam 36 feet, depth of hold 13 feet 6 inches. It is to be propelled by four propeller engines. At the bow there is to be a large and formidable iron prow or ram, nine feet in length.

STEVENS'S IMPROVEMENTS IN POINT INDICATORS FOR RAILWAYS.



Mr. J. J. Stevens, of Darlington Works, Southwark, has recently patented an invention for "Improvements in point indicators for railways."

This invention is intended to indicate to the person in charge of the working of the points, when such points are at a distance from him, the proper action or otherwise of the points which he desires to work.

For this purpose a pillar is erected at the side of or opposite to the points, on the upper part of which there is a diaphragm of any desired shape, divided into two parts, capable of being separated and of being brought close together; the lower part of the disc is made movable, while the other part is stationary. By a chain or bar, the movable part is connected to a wheel or pulley at the bottom or lower part of the pillar, and to this wheel is also connected a rod attached to the "fly-rail." The point is worked by the attendant, through chains, wires, or rods, by means of a pull-over lever, in the ordinary manner; and upon the "fly rail" being brought in contact with the main rail, the parts of the disc are separated or are closed, according to the manner in which the indicator is set to act. The attendant has thus indicated to him that the points have acted in the manner he has desired, or that they have not so acted, when he can take measures accordingly.

In order to render this a night as well as a day indicator, a lamp is erected at the back of the disc with coloured glasses, which may be made by showing a different colour, or by not showing any light at all, to indicate that the points have acted properly or the reverse.

In some cases the indicators are made double, that is to say, it is caused to face both to the attendant and to the driver of the train, and thus indicate to both parties in opposite directions at the same time.

Fig. 1 is a front elevation, and Fig. 2 is a side elevation, of one of the point indicators. Fig. 1 shows its connection to the fly-rail. A is a pillar, which may be of iron or wood; B is a plate fixed on the upper part of the pillar; C is a movable plate free to be moved up and down by a chain D passing over a pulley *a*, and fixed to the pulley E, which is connected by the rod F to the fly-rail G. H is a stop fixed on the pillar A, upon which the movable plate C rests when at the bottom

of its course. Fig. 3 is an elevation of the upper part of the pillar, showing the indicator shut. In order to make the indicator a night as well as a day signal, a lamp is fixed, and coloured glasses are fitted in the upper part of the pillar, as shown at Figs. 1 and 2. The coloured glasses are fixed in a frame which rests at bottom upon the movable plate C; and this frame rises and falls with the movable plate, as indicated by the dotted lines at the back of the fixed plate B. For the purpose of showing the white and green glasses, portions are cut away from the fixed and movable plates. For the proper working of the points, it is necessary that the fly-rail should be either entirely open, or wholly closed. When open, the movable plate is separated to its fullest extent, rests upon the stop, and the white glass is visible at the bottom of the fixed plate B, indicating "all clear," as shown at Fig. 1. When, on the contrary, the point is closed, and the fly-rail rests against the main-rail, the movable plate C is raised to the top of its course, and comes in contact with the bottom of the fixed plate B, and the green glass indicating caution is visible. In the event of the fly-rail being stopped from getting home in one direction or the other, the movable plate C does not reach the end of its course, and exposes the red glass indicating danger. Should the reverse movement be required in the indicator, then the pulley E is shifted from the axis *b* to the axis *c* on the pillar A.

Fig. 4 is a front elevation, and Fig. 5 a side view of an indicator for showing a signal both to the attendant working the points and to the engine-driver. A is the pillar, to the upper part of which metal plates B B are fixed; these plates terminate at top in eyes which receive and form bearings for the axis C. The movable indicator plate P fits into or is formed in a piece with a socket D, or fixture in the axis C. E E are quadrant frames, keyed or otherwise, fixed tight on the axis C; the lower part of the frames carries coloured glasses which move opposite apertures in the plates B B, to allow of the passage of light from the double-glassed lamp F, placed between them and on the top of the pillar A. G is a fixed plate upon which the movable indicator-plate rests, say to indicate the points right for a branch line; and H is another fixed plate against which the movable plate rests, to indicate say the points right for the main line. I is a guide-rail between the plates G and H. The fly-rail is connected to the movable indicator plate through a T lever, K, connecting-rods L L, and a cross-bar M, keyed or otherwise fixed on the axis C. As in the indicator first described, if the fly-rail should not get home in one direction or the other, the indicator plate does not reach one or other of the fixed plates G H, and the red glasses appear to show danger both to the engine-driver and to the pointsman.

THE INTERNATIONAL EXHIBITION.

Class I.

(From *The Times*.)

Sharp strictures have appeared in these columns on some of the classes of the Zollverein Department, and we have heard well-informed Germans fully admit their justice. It now affords us pleasure to apply very different language to Class I. of this department, and bestow upon it high praise. It must not be supposed that the Zollverein is adequately represented in this collection, which is confined almost entirely to Prussia and Nassau. Possibly, the other members of this great Customs' Union may have been disinclined to manifest too close an intimacy with Prussia; and one member, Hanover, has openly severed all connection, and exhibits her products in a corner beyond the frontier of the Union — a sad example of disunion and isolation. The collection has been formed under the direction of Von Dechen, of Bonn, and arranged by Dr. Hermann Wedding, of Berlin. The exhibitors are under no small degree of obligation to these gentlemen for the admirable manner in which they have accomplished their task. Of its kind, no collection in the Exhibition can be more instructive than this. It is accompanied by a descriptive catalogue in English (large 8vo., pp. 106), which is copious without superfluity, and is exactly what it should be, with the single exception that it contains no information as to prices. The sole interest of many of the objects of Class I. depends on price. At the Exhibition of 1851 several excellent priced catalogues were published, among which may be mentioned those of Austria, Saxony, Russia, Belgium, and Spain. However, as it is, this catalogue is a valuable record of important facts, scientific as well as commercial, and we advise all who are interested in the subject to endeavour to procure one, especially as it is not sold, but distributed gratuitously on application.

The collection contains almost every known description of iron ore — namely, magnetic oxide, specular ore, red and brown hæmatite, spathose carbonate, and argillaceous ore, including blackband; and even bog iron ore is not absent. The specimens, which are large and well-selected, are arranged in ascending geological order, and nearly every member of the series has its representative. Thus, ores are shown from igneous and metamorphic rocks, and the following formations:—The Devonian, the carboniferous, the new red sandstone, the magnesian limestone, the trias, the lias, the oolite, the wealden, the cretaceous, and the tertiaries. The gems are the magnificent spathose carbonates from Siegen. The upper Devonian beds of Westphalia and Nassau have been found very productive of red ores of good quality; and a series of these forms an important part of the general collection. Complete information will be found in the special catalogue concerning the mode of occurrence and the localities of all these ores. We would direct attention to the Nos. 620, 621, 622 of this catalogue (No. 695 in the official catalogue), as illustrative of a process of converting the fine powder of a brown iron ore into compact masses suitable for smelting. The powder is separated by washing with water in the state of mud, which is left to consolidate sufficiently in shallow pits, and is then made into bricks; these are dried and burnt, and so rendered fit for smelting.

We understand that this interesting and instructive collection of the mineral products of the Zollverein has been offered as a present to one of our national museums, and that it has been declined on account of want of space. We trust, however, that it will not leave London, as we believe that permanent and readily accessible collections of the mineral resources of foreign countries will prove of great practical utility to our miners and metallurgists. Such collections may not, like the showy objects of decorative art, attract flocks of sightseers, but they may convey solid instruction to the observant minds of the few, and so be the means of promoting the material interests of the nation in a degree that can be little anticipated. The value of a museum is not to be measured by the mere number of gazing spectators, but by the earnest students who frequent it for the sole desire of obtaining knowledge. We beg to assure the worthy Curator of the Museum of Practical Geology, who has addressed a letter to this journal, impugning the accuracy of our statement, that Mr. Blackwell's collection of ores is only dimly visible, but the preceding observations are not intended in disparagement of the collections under his charge. The Curator invites inspection of Mr. Blackwell's collection on *fine* days; but he should also have added *dull* days, which sometimes occur in London. We invite inspection in any kind of weather in confirmation of the accuracy of our statement; and we suggest that the positions assigned to the pottery and iron ores should be compared with respect to degree of illumination.

Austria presents many objects of interest in Class I., but there is no special collection of iron ores — not, certainly, because she is deficient in these valuable minerals. There is an excellent catalogue in English, published by order of the Minister for Commerce and National Economy, with the title of "Austria at the International Exhibition of 1862;" and in this it is stated (p. 9) that in 1860 about 1,000,000 tons of spathose carbonate, argillaceous ores, red, brown, and magnetic oxide of iron, were raised, and yielded upwards of 300,000 tons of pig iron. Under No. 44 will be found samples of iron ore, stated on good authority to have been derived from the lower Silurian beds. The catalogue contains much useful and well-digested information, not only about Class I., but the Austrian empire generally, with reference to its area, administration, and commerce. We have heard some of our ironmasters recently complain of the cessation of their trade with Austria in consequence of increased import duties; and on mentioning this circumstance a few days ago to one of the best authorities on the subject of iron in the Austrian dominions, a native resident in Styria, we were informed, in a strain of some exultation, that this change of duties had proved highly advantageous to the Austrian iron works. This may be true; but whether the change will tend to promote the prosperity of the empire generally, is another and very different question, about which nothing was said.

Russia is satisfactorily represented in Class I. The collection contains many interesting objects, but is displayed in a somewhat slovenly manner. Russia has long been celebrated for her production of certain descriptions of iron, to which we shall direct attention in a subsequent article. Scarcely any specimens of iron ore worthy of particular notice are shown. One of the most conspicuous objects is a 12-pounder cast-steel gun, which is reported to have sustained 4,000 rounds without injury.

Sweden, as might be anticipated, is strong in iron. Her chief ore is magnetic oxide, of which fine and characteristic specimens from various localities are exhibited. An instructive series of the far-famed Dannemora ores and the associated rocks specially deserves attention — see No. 9. The ores from this locality are among the finest in the world; and the iron which they yield always commands a high price, on account of its producing good steel. The Swedish iron ores differ much in quality, even when in appearance they closely resemble each other. One cause of the excellence of such as are considered the best is, without doubt, the absence of phosphorus, which is constantly present in sensible proportions in nearly all British iron ores, except the red hæmatites. The lake and bog iron ores of Sweden are well illustrated. The former are particularly interesting from their mode of occurrence. They are found at the bottom of the lakes and are dredged up, and after the lapse of many years again accumulate. They are in the state of small rounded particles and flat coinlike cakes, and consist essentially of brown iron ore. In 1860 not less than 22,000 tons of lake and bog ores were raised. They furnish a fluid pig iron suitable for fine castings in which strength is not an object.

Although we propose to reserve our observations on the iron and steel exhibited for a general and connected review, yet we cannot here refrain from inviting careful attention to one object in Class I. of Sweden. It is the fore part of an iron paddle steamer, 200 feet long and of 120-horse power, which, during a fog in September 1860, and while going at the rate of eight or nine knots an hour, struck on a rock. The iron, to use Mr. Cobden's once celebrated simile, was "crumpled up like a piece of brown paper," and yet the vessel got off and proceeded without difficulty to Stockholm, about 100 miles distant. A sketch is given, showing the exact spot where the blow was received in relation to the water line. The plates were made and the vessel was built at the Motala Iron Works. No object in the entire Exhibition can appear less attractive to the eye than this, and yet when its story is told not one should excite greater interest, at least in the minds of Englishmen. Here we have ocular demonstration of the rough treatment which a ship made of really good iron has received with comparative impunity. Plates to be used in the building of iron ships ought, like boiler plates, to be made of the most tenacious iron; whereas it is well known that in the manufacture of the so-called "boat-plates" the worst iron has often been employed. Cheapness has been the cry, and

"boat plates" have been required at prices utterly incompatible with goodness of quality. The ship-owner cuts down the shipbuilder, who in his turn cuts down the iron-master, and the result is a wretched thing called a ship, which will inevitably go to the bottom under a tithe of the injury sustained by the Swedish vessel. We know not how many lives have been sacrificed to cheap "boat-plates." There is good reason for believing that during the last few years more than one accident at sea would not have been attended with such wholesale destruction of human life as happened if the ships concerned had been made of even moderately good iron. In the reconstruction of the navy, this question of the best iron for plates is of vital importance. A bad plate for such a purpose is dear at any price, and no false economy must be tolerated with regard to the iron intended for Her Majesty's ships. We have reason to know that the authorities, both military and naval, are now fully impressed with the absolute necessity of employing, irrespective of cost, only those qualities of iron which have been found by experience best adapted to the various purposes of war. The experimental investigation on iron armour for ships has now extended over eighteen months, and is still in progress. Information has been collected on the subject from every source; the opinions of the proprietors or managers of many of the leading iron-making firms in different parts of the country have been procured and recorded; plates of iron of various kinds, and manufactured in different ways, have been tested under conditions calculated to afford decisive comparative results; the maker of each plate has been invited to witness the effects of its trial; and a spirit of laudable rivalry has thus been excited which cannot fail to secure the best results for the nation. There has been no hole-and-corner work, but all has been done in the presence of witnesses who would be sure to detect the least unfairness, and who, by thus seeing with their own eyes the effects of modern artillery—effects of which no adequate conception can otherwise be obtained—have derived practical information of the highest value. It has sometimes been amusing to witness the eager excitement, reminding one of the racecourse, evinced by spectators interested in an experiment. The Committee on Iron, to which this investigation has been confided, presented a few months ago a Blue-book, consisting of 283 pages, with numerous illustrations, not forgetting, like the Thames Embankment Committee, the index—and a second will assuredly follow. But this volume is, we believe, a sealed book.

(To be concluded next week.)

Correspondence.

[We do not hold ourselves responsible for the statements of our Correspondents.]

THE STRAIGHT LINE *VERSUS* THE WAVE LINE FOR VESSELS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—I confess to a little surprise that Mr. Cheverton can coolly talk about his "refutation" of the wave-line theory, when he has not yet brought a single argument against it, but merely made two or three assertions of the views he takes; and when he calls my illustrations *idle*, it must be on account of his perfect misunderstanding of the subject he writes upon; and I am sorry he is unable to see the complete appropriateness of my illustrations.

The *uniform motion* he advocates is quite unnecessary, because a vessel in motion is only in contact with each particle in its course for a few moments; it is constantly coming in contact with fresh particles, each of which has to receive a reciprocating motion at right angles, or nearly so, to the course of the vessel, and then the vessel has done with it for the rest of the voyage. As Mr. Scott Russell says: "The "form of least resistance should be such as to remove "the particles of water out of the way of the ship just "sufficiently far to let the largest section pass, and "not a jot farther;" and this *cannot* be accomplished by *uniform* motion.

Secondly, *uniform motion* cannot be obtained with any form! And if Mr. C. will try experiments before he writes, he will find that water is quite as difficult to coerce into uniform motion as machinery.

I must repeat my advice to Mr. Cheverton to refresh his memory by referring to the many published arguments upon the subject, and if he refers to Mr. Scott Russell's admirable papers read at the Institute of Naval Architects, he will find every objection he can possibly bring against it fully answered.

I am, Sir,
Your obedient servant,
T. MOY.

1 Clifford's Inn, July 22, 1862.

COMBUSTION IN CONDENSED AIR.

SIR,—It has long been known that the heat and light evolved when any combustible matter is burned vary in a high but imperfectly-determined ratio with every variation in the density of the atmosphere in which this combustion is effected. Sir Humphrey Davy, more than forty years ago, tried some experiments, the result of which was to show that the heat, &c., from burning sulphur and alcohol rapidly diminished when the fuel was burnt in rarefied air, and increased if the air was condensed. More recently, Dr. Frankland has carried through an elaborate series of experiments by burning candles and other combustibles at different heights during an ascent of Mont Blanc. The results were explained in a lecture delivered before the Royal Society last year.

From the facts ascertained by Dr. Frankland, he came to the conclusion, that while the quantity of material burnt did not perceptibly alter under every range of atmospheric pressure, the proportion of light evolved decreased 5·1-hundredths for every fall of one inch in the mercurial barometer; that is to say, that if the unit of light from a candle or lamp, when the barometer marks 30 inches, is assumed to be =100, the light emitted when the mercury falls to 29° is less than 95, sinks below 90 when the air is of a density represented by 28 inches, and so on. This proportion Dr. Frankland believes to be accurate: at all events, within a certain range both of the ascending and the descending scales of atmospheric pressure.

The visible effects upon the flame of candles burnt under diminished densities of air are precisely those which might have been predicted on *à priori* considerations. As the air becomes rarer, the flame becomes large and feeble; the blue non-luminous portion augments in size until, at a certain point of altitude—*id est*, of rarefaction—it occupies the whole space filled with the burning particles. The reason is obvious. Every atom of hydrogen requires, by weight, about 8 times the same quantity of oxygen to burn it; and every grain of carbon requires three of oxygen, forming respectively water and carbonic acid gas. As 100 cubic inches of air, at the ordinary pressure, contain about 6 grains of oxygen, and as combustion stops when the supply of oxygen is less than double (treble?), the theoretical quantum required for combination, the gaseous or vaporised particles of fuel must, in burning, occupy such a space as that for every grain consumed they shall obtain a feeding supply of at least 200 cubic inches of air. This is the case at ordinary densities, with the barometer at 30°. As the density diminishes, the space must be enlarged, and *vice versâ*. The consequent influence upon the development of light and heat, when the air grows denser, may be assigned to a combination of two causes, viz.:—

I. A larger number of burning and incandescent particles are packed into the same space.

II. The atoms of oxygen and fuel are pressed into closer contact, and the chemical action of which the devolution of heat and light is the consequence, proceeds with increased intensity.

As a familiar example, we know that the slight condensation of air produced by cold ($=\frac{1}{480}$ in volume for every 1° Fahr.) causes a noticeable increase in the heat and light of a common fire, finding expression in the phrase that it "burns frosty."

Dr. Frankland believes that his "modulus" of 5 in the 100 for every mercurial inch of barometrical pressure obtains only through a limited range, being too high for very low pressures. *E converso*, we may conclude that it is too low for the higher densities. Experiments on this point have yet to be tried. But, taking the average as it stands, and as it has been tested by sufficient experience, we come to this conclusion—that if the atmosphere were condensed to a double pressure, viz. 60 inches of mercury, the heat and light evolved from any burning fuel would be increased in the proportion of $5{\cdot}1 \times 30$: 100; that is to say, by 153 per cent. At 90 inches the increase would be 306; and at 120 inches—representing a "bursting pressure" on the reservoir of only 45 lbs. per square inch—the gain would be at the lowest estimate 459 per cent., enhancing the original 100 of calorific or luminous effect to 559; thus in practice eliciting a nearly sixfold useful result as obtained from the combustion of any given quantity of fuel.

In its application to illuminative purposes there are some serious practical difficulties to be overcome; but the principle thus enunciated can be utilised in the production of heat without encountering any obstacles which cannot be surmounted by a little ingenuity. It is not difficult to construct chambers of any size air-tight and strong enough to bear heavy pressure, into which, as into a diving-bell or other subaqueous apparatus, air is forced and renewed, in quantities sufficient to meet the demands of the furnaces, &c. at work, and of the men employed to work them. The anticipated results are, that the fuel is more rapidly and freely burnt; that the heat produced is enormously intensified, and, at the same time, kept under complete command; that (when required) a degree of heat can be obtained by the combustion of ordinary coke or coal, exceeding that now attainable only by the oxyhydrogen blow-pipe; that all smoke will be consumed; and that the products of combustion, or of the various smelting and other processes carried on in the furnace, are under complete command, and may be so treated as to neutralise everything that is offensive, and utilise everything that is useful.

J.

THE ADMIRALTY AND INVENTORS.

SIR,—Accept my best thanks for the kindly notice of my suggestions and propositions, which appeared in last week's Magazine, under the head of "The Iron Walls of Old England," in the concluding letter of your able correspondent, "Civilian." I am greatly obliged by all manly, open, and honest criticism, for it is the true furnace to try the pure metal, if it exist. My only object in submitting my plans and propositions to the English Governmental authorities has been to do good, by simply suggesting such ideas as appeared to me feasible, as a working practical engineer of thirty years' experience among some of the largest works of the kingdom. But I regret to say my settled conviction is, that unless a man can command a full purse or high patronage, his offers (be they ever so good or valuable) will be coolly rejected by a stereotyped red tape letter, which neither condemns, approves, or adopts. This principle of "systematic rejection" is most ably shown in your leading article, page 30, "Inventors and the Admiralty," and in which you propose, or rather repeat your prior propositions, for the formation of a qualified and independent committee of gentlemen, of practical experience and liberal views, who will patiently and industriously separate the wheat from the chaff, by testing fairly and practically those samples which will bear fair handling and recognition, and by which assortment immense advantages would be secured for the country's best interests, in the selection of that which is now rejected, without reason or judgment; for I had a convincing proof of this a few years since in the receipt of an official letter, in reply to an offer of mine (made in writing), which I followed up by twenty-one personal applications; and this reply coolly informed me "that my plans and models had received investigation and inspection, and were considered not adapted for the service;" when I proved at once that my plans and models were in my own possession, and had never been examined or investigated by this (so-called) Committee in any way whatever! I was obliged to be content with the addenda information, "that I was not the only one, by many, who had been served so badly."

It is high time for England's best interests that such things should be reformed. It is this which is driving our best mechanics and inventive talent out of the kingdom. "Fair play and no favour" is all that is honestly asked for, by good and deserving men, who have their country's best interests at heart; and I trust the time is not far distant when an Englishman will find his best friends and his highest patronage can be secured in the land of his birth and training.

Yours respectfully,
W. AUSTIN, C.E.

31 Hamilton Terrace, Milford, S. Wales,
July 19, 1862.

Gossip.

Preparations are being made in Westminster Abbey for the reception of a stained glass window, which has just been completed, to perpetuate the memory of the Stephensons and other eminent engineers. In the body of the window some of the greatest engineering and architectural works of ancient and modern times are represented, and above these, at the top of the window, in five-foil, bust portraits of eminent engineers are appropriately arranged. A figure of Robert Stephenson (whose remains lie in the Abbey) is placed in the centre. Above, is his father, George Stephenson. On one side is Thomas Telford; on the other, John Smeaton; and below, the figures of James Watt, and Joseph Rennie. In order to give modern costume the more dignified and imposing appearance which belongs to the ancients, a scarf is thrown over the shoulders of each individual. The architectural works represented are bordered with ornamental tracery on each side. They consist of, on the one half of the window, the ark, the erecting of the tabernacle, the first temple, the second temple, and Menai bridge; and on the other half, the building of Nineveh, the treasure cities of Egypt, the aqueduct near Pyrgo, the Colosseum at Rome, and the high-level bridge at Newcastle-upon-Tyne.

At the evening sitting of the House of Commons on Tuesday last, General Lindsay moved a resolution to the effect that Captain Grant was entitled to some remuneration for the services he had rendered in the improvement of the means of cooking for the army. He explained the circumstances in 1855, under which Captain Grant had set up his apparatus in the camp at Aldershott, and described its superiority over the old practice which had prevailed in the barracks. It had been in operation at Aldershott ever since, and at the present time cooking was done by it for 20,000 men. Not only so, but the system had been extended to Shorncliffe, and Woolwich, and other places. But Captain Grant had not received any compensation whatever, and was 280*l.* out of pocket; and this was certainly not fair treatment. There were seven reports from commissions, consisting of commissioned officers, in which testimony was borne to the efficiency of Captain Grant's apparatus. Amongst the officers who reported in favour of it were Lord Rokeby, Sir R. Dacre, Sir J. Pennefather, and Brigadier Stanelly.—The motion was opposed by Sir G. C. Lewis, and after some discussion was negatived by a majority of one vote, 51 voting for it, and 52 against.

On Tuesday last, the Racoon, 22, 1,467 tons, 400-horse power, was taken out of Chatham harbour on Tuesday to the Maplin Sands, for the purpose of testing the working of her engines, and ascertaining her rate of speed since the alteration of her machinery, which was made at Chatham under the superintendence of Mr. Baker, chief engineer of the dockyard. The trial was made under the direction of Capt. Thompson, commanding the steam reserve in the Medway; Mr. Rumble, chief inspector of machinery afloat; and Mr. Baker and staff, from Chatham dockyard; the engines being in charge of Mr. Bonney, chief engineer of the Racoon. During the trial six runs were made at the measured mile, with full boiler-power, giving an average of 10·75 knots per hour at full speed, half-speed not being tried. The result of the trial was hardly so satisfactory as had been anticipated, the vessel, since the alterations and improvements made in her machinery, having been expected to attain a higher rate of speed. During the runs the number of revolutions made by the screw was 58 at full speed, with a pitch of 26, the screw being Smith's common propeller, not variable, with the leading corners removed. The draught of water forward was 16 feet, and aft 17 feet 2 inches; vacuum, 26; and the temperature of the engine-room, 68.

"One object," writes Mr. W. Lassall, from Malta, on the 13th of May last, "on which I scarcely intended to bestow any attention, has fascinated me greatly—I allude to the moon, in which I see minute details with a hardness and sharpness and reality I have never seen before. My opportunities of scrutiny have, however, been fewer than might have been supposed from my having frequently been engaged in showing this very popular object to many visitors. Yet, notwithstanding that, I have thus been able to see more into the moon than ever before—so much so, that I believe if a carpet the size of Lincoln's-inn-fields were laid down upon its surface, I should be able to tell whether it was round or square. I see nothing more than a repetition of the same volcanic texture, the same cold, crude, silent, and desolate character which smaller telescopes usually exhibit."

FANCY RIFLES.—A correspondent of the *Times* says:—"The tabular statement of which I send you a copy, giving the result of the trials recently made under the superintendence of the Ordnance Select Committee, to test the relative merits of the small-bore service rifles, is so favourable to Lancaster's system that I am induced to beg you will inform those interested as I am in procuring the best rifle, whether these trials, reported to have been made with the greatest care, are to be relied on, and whether the oval bore is preferred in the service. These returns show that the small-bore Enfield is superior to the Whitworth, and that the Lancaster is 50 per cent. better at all ranges. I understand that the diagrams represent the targets made by five rifles of each kind firing 20 rounds of Whitworth ammunition; that the arms were not only all made under the direction of Colonel Dixon at Enfield, but that the Whitworths were finished and turned out by Mr. Whitworth himself, impressed with all the excellence his peculiar system is capable of imparting:—

EXPERIMENTS WITH SMALL-BORE (·451) RIFLES.

	300 Yds. Inches.	500 Yds. Feet.	800 Yds. Feet.	1000 Yds. Feet.	1200 Yds. Feet.
Lancaster	4·20	0·50	1·01	1·87	3·90
Enfield	5·25	0·87	1·76	2·55	4·40
Whitworth	5·76	0·70	1·62	2·88	5·52

Mr. W. Baliard, of New York, has an invention, which consists of constructing a vessel of frames of iron and interposed frames of wood, and in covering the frame with two or more series of flat diagonal bars crossing each other in opposite directions, and an outer series of longitudinal plates, the whole being bolted together and combining to make a very strong vessel, capable, in a high degree, of resisting the impact of heavy projectiles. Its ports are made with angular or V-shaped faces, that the projectiles may glance off in striking. Between the port-holes there are constructed heavy wooden buttresses, which make the ports like the embrasures of forts.

The International Electric Telegraph Company is about to lay a cable from the Ness Point to the coast of Holland, and men are now engaged in laying down pipes to carry the wire from Lowestoft telegraph office to the Ness Point.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINE, &c., 34, 65, 85.
BOILERS AND FURNACES, &c., 92.
ROADS AND VEHICLES, &c., 33, 44, 77.
SHIPS AND BOATS, &c., 36, 47, 72.
CULTIVATION OF SOIL, &c., 27, 71.
FOOD AND BEVERAGES, &c., 18, 63.
FIBROUS FABRICS, &c., 20, 31, 45, 46, 47, 54, 64, 87.
BUILDING MATERIALS, &c., 76.
LIGHTING, HEATING, &c., 25, 30, 32, 37, 60, 61, 66, 67, 69, 73, 81, 84, 90.
FURNITURE AND APPAREL, &c., 19, 26, 40, 43, 51, 53, 57, 75, 91, 94.
METALS, &c., 28, 29, 56, 86, 88.
CHEMISTRY AND PHOTOGRAPHY, &c., 23, 95.
ELECTRICAL APPARATUS, &c., 58, 59, 79.
WARFARE, &c., 22, 24, 52, 68, 89.
LETTER-PRESS PRINTING, &c., 38.
MISCELLANEOUS, 21, 35, 39, 41, 42, 43, 50, 55, 62, 70, 74, 78, 80, 82, 83, 93.

18. W. EDGE. *Improved apparatus for roasting coffee.* Dated Jan. 2, 1862. (A communication.)

This apparatus is composed of a sphere of sheet iron or other metal (to be turned over a fire by the aid of a crank) surrounded by an envelope or casing of similar material, or of cast iron, which will cause the flame and smoke from a fire beneath to circulate all around the sphere, and which will have a fixed and a movable part. The fixed part (which should be of the thinnest cast iron) will have a sloping cut to permit the passage of the revolving sphere, the axle of which it will support, and to which it will be nearly concentric, but, by reason of the sloping cut, interrupted, and, as it were, cut by a horizontal plane; and on this side it will be covered with another casing slightly eccentric to and forming part of the first, a passage being left for the smoke which will redescend between them and escape through a pipe joined thereto. The movable part of the casing will be arranged so as to lift and turn back behind the fixed part to give passage to the sphere when it is desired to inspect or arrest the roasting. *Patent abandoned.*

19. A. M. P. AIRIAN. *A new musical instrument called "lute organ."* Dated Jan. 2, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

20. W. A. FELL. *Improvements in the manufacture of bobbins, and in the means or apparatus employed therein.* Dated Jan. 2, 1862.

This consists in a mode of manufacturing bobbins in parts held together by screwing. The formation of the fitting parts, and the connection thereof, are obtained by mechanical means. *Patent completed.*

21. M. CARTWRIGHT. *Improvements in the manufacture of models and of plates or pieces for artificial teeth.* Dated Jan. 2, 1862.

This consists in a method of manufacturing models used for preparing "plates" or "pieces" for artificial teeth of vulcanite, ebonite, or hardened rubber, alone or combined with soft vulcanized rubber; also in combining or amalgamating indiarubber and guttapercha with metals for the manufacture of artificial teeth or pieces, and for other purposes. *Patent abandoned.*

22. G. JEFFRIES. *Improvements in breech-loading fire-arms and in the apparatus for the manufacture of cartridges.* Dated Jan. 2, 1862.

According to one part of this invention, the inventor mounts the barrels on a centre or axis on one side of the centre line of the piece, and at a distance of some inches in advance of the breech end of the barrel. This centre or axis is carried in a suitable bearing connected with the false breech, and which is flat and at right angles to the centre line. The breech ends of the barrels are so made as to fit closely against the false breech, when the barrels are in their places ready for firing; but in turning the barrels partly round laterally about their axes, the breech ends of the barrels will immediately be freed from the false breech, the axis as before mentioned being placed at a distance from the centre line of the piece. When the barrels have been moved a sufficient distance sideways to allow cartridges to be introduced freely into their breech ends, they are stopped by a spring-catch provided for the purpose. The barrels are retained firmly in position for firing by a specially-constructed wedge piece. *Patent completed.*

23. H. ESCHWEGE. *Improvements in treating wood and other vegetable spirit.* Dated Jan. 2, 1862.

The patentee has ascertained by numerous experiments that charcoal—particularly well-burnt wood charcoal—when used at ordinary temperatures in a series of filters of sufficient size, has a most beneficial effect in purifying spirit (whether obtained in the manner of wood spirit, or from fermented vegetable substances), if the affinity which the spirit has for certain impurities be first destroyed by largely diluting it with water, and then subjecting this distilled spirit to the action of a series of wood-charcoal filters (preferring at all times that the temperature should not exceed 70° Fahr.), so that each successive filter shall effect the filtration of a purer and purer spirit, the same spirit never passing through a filter to which it has already yielded its impurities, but only through filters lower down in the series. When it is ascertained that the filtered diluted spirit which is coming away from the last filter of the series is not any longer sufficiently pure, the first filter of the series is to be removed and a fresh filter to be introduced and made the last filter of the series; and the supply of diluted spirit is to be introduced into what was the second filter of the series, and so on continuously as the filters require to be changed. After this process of purification the filtered spirit is to be brought to the desired strength by distillation. *Patent completed.*

24. E. NUGENT. *Improvements in fire-arms.* Dated Jan. 3, 1862.

This relates to a class of fire arms intended to be used chiefly for field service in the army, and for action in the navy. The arm is designed to fire small balls with great rapidity and accuracy by giving the usual form and partially fixed support of a gun-carriage to an arm capable of combining accuracy and rapidity. The invention is not described in detail apart from the drawings. *Patent completed.*

25. G. STRACEY. *Improvements in the manufacture of artificial fuel (fuel).* Dated Jan. 3, 1862.

Here the inventor takes aluminous matter and carbonate of lime, and combines them with coal and saw-dust and a very small proportion of cut straw, in the proportions of about four parts of carbonate of lime to one of aluminous matter, and about four parts of saw-dust to one part of coal, and he mixes these together with a small quantity of cut straw, and this mixture he subjects to a powerful pressure, forming it into blocks of different sizes as desired. The above fuel requires to have a small portion of coal or coke burnt with it to produce a brilliant and powerful fire, and fuel thus manufactured is considerably less costly than coal or coke, and is well adapted for furnaces, kitchen-ranges, stoves, hot-houses, &c. *Patent abandoned.*

26. T. S. BELLOCHE and H. BOLLACK. *An improved parasol.* Dated Jan. 3, 1862.

This consists in constructing the frames of parasols in two parts, jointed together with a free hinge; the top part of the frame is attached to the handle, and overlaps and works freely on it; the other or overlapped portion of the frame is attached in the usual way at the top. When the parasol is closed, the lower half of the frame, with the cover stretched upon it, will fold back over the upper part, forming a shape similar to a cone, the apex downwards. By forming the edge of the cover with a border or trimming of artificial flowers, the parasol when shut will represent a large bouquet or vase of flowers. *Patent completed.*

27. W. E. GEDGE. *Improvements in apparatus for dressing, cleaning, or sifting grain.* (A communication.) Dated Jan. 4, 1862.

This invention is not described apart from the drawings. *Patent completed.*

28. G. W. ARUNDELL. *An improved method and improved apparatus for treating and dressing ores and minerals, particularly applicable to tin, lead, copper, zinc, and iron ores.* (A communication.) Dated Jan. 4, 1862.

This invention is not described apart from the drawings. *Patent completed.*

29. I. W. ARUNDELL. *An improved method and improved apparatus for removing impurities from coal, parts of which invention are applicable for the separation and cleansing of ores and other minerals.* (A communication.) Dated Jan. 4, 1862.

Here the screenings are caused to fall upon a shoot over which a stream of water flows, and with the water are passed by the shoot into a hollow drum perforated at the sides, this first drum being placed within a larger drum perforated with smaller holes than the inner drum, the screenings as they fall from the drum being deposited on to a rotating picking table; a boy removes all slate and other impurities, and a fixed scraper causes the cleaned coal to fall into a tram-wagon, or other receptacle. *Patent abandoned.*

30. I. W. ARUNDELL. *An improved method of communicating motion to fan ventilators, particularly applicable to ventilating mines.* (A communication.) Dated Jan. 4, 1862.

This consists in having a screw cut on the axis of the fans in which the teeth of a toothed wheel of suitable size work. The teeth of the toothed wheel are cut obliquely, and of the same pitch as the screw. The wheel must be of sufficient size to cause the fans to revolve with the required velocity, but the size of the wheel need not be greater than to cause the fan to revolve ten times while the wheel revolves once. The wheel may be driven by manual or other motive power. *Patent abandoned.*

31. C. CROSS and E. PADMORE. *Improvements in the manufacture of piled fabrics, and in machinery or apparatus employed therein.* Dated Jan. 4, 1862.

This consists: 1, in arranging the pick so as to form both the foundation and pile of the fabric; 2, in introducing various materials of different colours into the pile fabrics; 3, in cutting the pile of any weft pile fabric as the fabric is woven, by introducing into each race a strip of metal, having a sharp cutting edge, so that, as the fabric advances to the breast beam, each race may be cut and the pile thereby formed. *Patent abandoned.*

32. R. H. COTTER. *An improved apparatus for suddenly producing a permanent light.* Dated Jan. 4, 1862.

This consists of a lamp provided with a wick for burning paraffine, coal oil, or other inflammable fluid, in connection with an apparatus for striking an ordinary Congreve or other friction match. *Patent abandoned.*

33. G. LEYSHON and D. BECKLEY. *An improvement or improvements in breaks for retarding and stopping carriages on railways.* Dated Jan. 4, 1862.

In carrying out this invention, the inventors fix upon one or both of the axles of the carriage a disc, or break-wheel, and over the said break-wheel or wheels is a shaft supported in bearings on the bottom of the carriage, and running parallel with the longer sides of the carriage. Around each of the break-wheels is a clip or nearly circular band or bar of iron, and on the said shaft, and immediately above the break-wheel, is a screw which engages in a screw-box or nut on one end of the said clip. The other end of the said clip has a nut through a hole in which the shaft passes, the said nut being incapable of moving along the said shaft. When the shaft is turned in one direction, the two ends of the clip are brought nearer to each other, and the clip is tightened on the break-wheel; and when the shaft is turned in the other direction, the two ends of the clip are separated, and the clip is no longer pressed upon the break-wheel. *Patent abandoned.*

34. J. HOWDEN. *Improvements in steam-engines and boilers.* Dated Jan. 4, 1862.

This invention refers to a previous patent, dated Nov. 21, 1860, and comprises much detail, which we cannot devote space to here. *Patent completed.*

35. H. D. POCHIN. *An improved soap or size.* Dated Jan. 4, 1862.

Here the patentee takes the ordinary resin of commerce and grinds it to a fine powder, and afterwards mixes it with soda-ash or pearl-ash. He places this mixture in a pan and heats it either with steam or fire heat until complete combination has been effected. When cold he breaks it up into small pieces or grinds it to powder. In making the size he dissolves a certain quantity of the anhydrous soap in water, and adds thereto an aqueous solution of his patent aluminous cake, ammonia, alum, or other aluminous salt. *Patent completed.*

36. G. T. BOUSFIELD. *Certain new and useful improvements in machinery for propelling water-craft.* (A communication.) Dated Jan. 4, 1862.

The object here is to enable screw propellers to be located at or near the longitudinal centre of a vessel, and at the same time to be wholly or partially submerged. To this end the first part of the invention consists in combining a screw propeller with a recess in the side of the body of the vessel, so that a portion of the propeller revolves in the recess and a portion thereof revolves outside of the recess. The object of the second part is to enable a gudgeon of the shaft of a screw propeller to be sustained in a bearing under the surface of the water and outside of the vessel's side: this part of the invention consists in combining a screw propeller with a chamber projecting from the vessel's side, the chamber being located in such a position that it contains within it the pillow block of the propeller shaft. *Patent completed.*

37. A. WARNER. *Improvements in preparing materials for and in purifying coal gas.* Dated Jan. 4, 1862.

Here the inventor employs the cinder or oxide of iron obtained from puddling, reheating, and refining furnaces used in the manufacture of iron, and which are now, for the most part, waste products in such manufacture. These materials are ground and then washed in water, and are used in apparatus such as are used when purifying gas by what are known as the dry processes. *Patent abandoned.*

38. J. CORYTON. *An improved type machine.* Dated Jan. 4, 1862.

This consists of a machine in which the types are successively stamped upon a travelling bar of lead, or other soft substance, the matrices being composed in a steel or other hard metal box, which moves at right angles, or nearly so, to such bar of lead, &c. The words and symbols when formed are set up in a grooved chase, and are available as printing surfaces in any of the modes of printing ordinarily employed. *Patent abandoned.*

39. A. V. NEWTON. *An improved manufacture of cigars.* (A communication.) Dated Jan. 6, 1862.

Here a gauze tubing is filled with fine cut tobacco and surrounded by a binder and wrapper of leaf tobacco. *Patent completed.*

40. G. G. W. and J. BETJEMANN. *Improvements in dressing-cases, applicable to other cases and boxes.* Dated Jan. 6, 1862.

This consists in an arrangement of quadrants, levers, and connecting rods, for opening or letting down a front flap and of opening out one side tray at one or both sides of the dressing-case, upon the raising of the top or lid thereof. The action may be applied to both flap and side tray, or side trays, or to either separately. *Patent completed.*

41. P. B. O'NEILL. *Improvements in screw wrenches or spanners.* Dated Jan. 6, 1862.

Here, when constructing a wrench, the inventor employs a suitable rod or metal bar, one end of which is formed as a handle, and the other end is forked. To the ends of the two prongs of the forked bar one jaw of the wrench is fixed firmly; the other, or movable jaw, has a slit formed in it, through which the prongs of the fork pass, so that the movable jaw may be capable of sliding on the forked bar towards or from the fixed jaw. For securing the movable jaw two spring catches, turning on a pin or pins, are fitted into the slot through the jaw, so that they stand in the space between the prongs of the forked bar, and teeth are formed on the inner sides of each prong of the fork for these catches to take into. Hence, in order to shift the movable jaw from one position to another, it is only necessary to free the spring catches from the teeth on the forked bar to slide the jaw to the position required, and allow the catches again to drop into the teeth. Modifications are included. *Patent completed.*

42. W. T. KITE. *Improvements in the manufacture of starch and in apparatus employed therein.* Dated Jan. 6, 1862.

Here the inventor takes flour, and makes it into dough by kneading it with a suitable quantity of water. The dough when made is placed in a trough or vessel in which are surfaces having points or spikes upon them, and these surfaces, having a vibratory or other movement communicated to them, continually perforate the dough; streams of water run over the dough during this operation, and wash away the starch from it. The spikes penetrating the mass of dough insure the access of the water to every portion of it. The water with the starch escapes from the trough or vessel through holes covered with wire gauze or finely perforated metal; it runs into a vat where the starch is deposited; the supernatant water is let off, and the starch is again mixed up with a small quantity of water, to which acetic acid is added. This mixture is allowed to stand, by which the impurities from the starch rise to the surface, and are skimmed off. When the purification is complete, the starch is made up for sale in the usual way. *Patent abandoned.*

43. F. BROWN. *Improvements in kitchen ranges and cooking apparatus.* Dated Jan. 6, 1862.

Here a boiler is applied to the side of the fireplace of a range, and is so arranged as to allow heat and the products of combustion to pass under or over, or both over and under, the boiler at the side of the fire. Beyond the boiler is an oven or ovens, so arranged with a flue or flues that the heat and products after so passing the boiler (at the side of the fire) may then be conducted over or under, or both under and over, the oven or ovens which are beyond the boiler. Dampers or slides are used to regulate and direct the course of the heat and products of combustion from the fire to the oven or ovens beyond the boiler. A hot plate or plates is or are arranged over the boiler and oven or ovens. *Patent completed.*

44. F. SHAW. *A system of stopping railway trains.* Dated Jan. 7, 1862.

This consists in an arrangement whereby all the carriages or wagons composing a train may be furnished with independent break power, and to effect this object the patentee proposes to apply breaks to all the wheels of a four-wheel carriage, and to the four outer wheels of a carriage having six wheels, the breaks to be so connected to the buffer rods by spring levers that, by pressure upon the buffers, the breaks are applied to the periphery of the wheels. *Patent completed.*

45. I. HIGGINS and T. S. WHITWORTH. *Improvements in machinery or apparatus for spinning and doubling cotton and other fibrous materials.* Dated Jan. 7, 1862.

This consists, 1, in a method of obtaining the drag, and consists in causing the spindle to be pressed by a metallic surface. According to another part of the invention the patentees support the spindle by a tube projecting into the bobbin, and the bobbin by a cap which is carried by the spindle. Another part consists in so mounting the flyer that it may be moved sideways from the spindle, so as to facilitate the removal of the cop or bobbin. Another part relates to a method of obtaining an end for the commencement of another cop or bobbin, and consists in a provision for raising the spindle, so as to bring a bare part up to the level of the guide or other apparatus through which the yarn or thread passes. *Patent completed.*

46. J. TATHAM. *Improvements in machinery or apparatus for preparing, spinning, and doubling cotton and other fibrous materials.* Dated Jan. 7, 1862.

This consists, 1, in the use of that form of sheet metal usually termed corrugated, for the covers of scutchers or openers, also for the covers of carding engines, and for the manufacture of cylinders to be used as surface motion drums, that is to say, such drums as are used for unwinding or winding fibrous materials by revolving in contact therewith. Also the patentee uses the said corrugated metal for making cylinders to be used as clearers for the top rollers of preparing and spinning machinery. The drums and rollers as aforesaid, may be fitted with axles in any ordinary way. Another part of the invention relates to the doffer or stripper combs of carding engines, and consists, 1, in forming them after the manner of "angle iron;" or he forms the section of the said combs or strippers as a curve which may constitute a whole circle. *Patent completed.*

47. B. FOSTER. *Improvements in machinery or apparatus for spinning and doubling wool and other fibrous materials.* Dated Jan. 7, 1862.

Provisional protection has not been allowed for this invention.

48. A. WALLIS and C. HASLEM. *Improvements in rotary screens.* Dated Jan. 7, 1862.

Here, in forming rotary screens, the patentees make up a frame of metal bars, as before, and these bars are notched at the periphery of the drum externally at the places where the wire (which is applied as before or in separate hoops) rests upon them. When the bars so formed are made up into a frame, these notches are to be on the exterior of the frame; the notches in the bar receive the wire and prevent it moving laterally. The wire is prevented springing out of the notches by riveting over the projections or studs between the coils of wire. *Patent completed.*

49. D. BEALE. *An improved method of fastening iron plates to ships' sides.* Dated Jan. 8, 1862.

Here the inventor commences at the lower part of the vessel by driving from the outside peculiar formed bolts, which he calls "dovetail eye bolts," through the eye of which is inserted a dowel or pin through the vessel's side, leaving the head of the bolt and dowel or pin projecting outside the vessel. The plates are so constructed with recesses at the lower edge as to receive the dovetail head of the bolt, and the dowel or pin, and the upper edge with holes to receive the dowels or pins only. One end of the plates will be grooved, and the other end tongued. The plates are then placed so that the heads of the bolts and dowels or pins shall fit in the recesses of the same; another row of the same kind of bolts without the dowel or pin is driven above these plates, and then the dowel or pin is driven through the eye of the bolt, and into the holes or recesses in the upper edge of the plates, whereby saving of labour is effected and few bolts required. The bolts are fastened on the inside of the vessel by nuts and screws. *Patent abandoned.*

50. L. WUNDER. *Improvements in the manufacture and composition of soap.* Dated Jan. 8, 1862.

Here the soap is to be composed of equal parts of the best tallow and of the finest cocoa-nut oil, well boiled with water, to which will be added about 2 lbs. weight of salt, and a quarter of a pound of burnt alum ("alumium ustum") for every 200 lbs. weight of the above fatty matters, to which, when taken off clean from the deposit, will be added natron and kali, in the proportion of about 90 lbs. of natron and 100 lbs. of kali to every 200 lbs. of the fatty matters. To every 100 lbs. weight of the mass will be added about 2 lbs. weight of finest catechu, and about 5 oz. of tincture of armica, and it will be perfumed by the addition of about 1 oz. of cinnamon oil, 2 oz. of oil of lavender, and 2 oz. of cumin oil or other perfumes. *Patent abandoned.*

51. A. HEATH. *Improvements in the construction of ink-stands.* Dated Jan. 8, 1862.

This consists principally in being able to fill the smaller vessels or ink-cup at pleasure, from the larger one in which it is placed, in protecting the point of the pen from the sediment of the ink, and in limiting the quantity of ink in the cup, so that the pen can only take up so much as it will hold, but which quantity may be increased or diminished, to suit the pen in use at the pleasure of the writer. *Patent completed.*

52. S. JESSON, J. BATSON, J. MOORE, and J. ROBERTS. *Improvements in the manufacture of gun-barrels and wrought-iron tubing.* Dated Jan. 8, 1862.

Here the inventors take a bloom of wrought iron, and, after beating it, pass it through a pair of grooved rolls, by which it is elongated and its diameter reduced. This billet, while hot, is now passed through a second pair of grooved rolls, the grooves of which rolls give to the billet the shape of a semi-hollow cylinder or half tube, the interior being nearly semi-cylindrical, and the exterior having three or more planes or sides. The edges of the half-tube are not plain, but have each a bead or rib running along its whole length. The inventors take a second billet, and by grooved rolls they roll it into a shape similar to that last described, excepting that, in place of ribs or beads running along the edges, they make grooves or depressions in the edges of a figure corresponding to that of the ribs or beads on the first-made half-tube. The two half tubes are then placed together, so that the beads or ribs on the edges of one engage in the grooves or depressions in the edges of the other. The two half-tubes thus fitted together are heated in a mill furnace, the partially-formed tube resting on one of the planes on its outside. It is heated to a welding heat, and, properly heated, is removed from the furnace, and passed through a pair of grooved rolls, by the pressure of which the two half tubes are welded together. *Patent abandoned.*

53. C. and T. PILKINGTON. *Improvements in skates.* Dated Jan. 8, 1862.

This consists of a metallic skate composed of any suitable description of metal, such as iron, steel, tin, zinc, brass, German silver, or other metal, or combination of tin or more metals, either in alloy or otherwise. The form of the body of the skate is stamped out or raised by dies in the usual form of skate clog. The sole is similarly shaped and soldered on. *Patent completed.*

54. J. BARBER. *Improvements in hand-mules, consisting of a break and backing off motion.* Dated Jan. 8, 1862.

Here the inventor places a pulley upon the main shaft of the mule, and a corresponding fast and loose pulley on the first mover, the strap being adjusted so as to drive in the contrary direction to the revolution of the driving pulley. This strap passes through a strap-fork attached to a sliding-bar, to which is connected a weighted bell-crank lever, which has a constant tendency to throw the strap on to the fast pulley, but is prevented from doing so by a catch which holds against a projection on the sliding-bar. A short time before the 'draw' or stretch of yarn has received its full quantity of twist, a finger on the twist-shaft strikes the above-mentioned catch, releasing the sliding-bar, which the weighted lever sets in motion, causing it, by means of the strap-fork attached thereto, to throw the strap from the loose pulley on to the fast pulleys. The strap thus applied, and moving in the opposite direction to the driving-strap, acts as a powerful break in checking the velocity of the first mover, and reversing its motion, thus entirely superseding the manual labour of the spinner in "breaking" and "backing off." The breaking is finished and the backing off commenced simultaneously with the time that the draw has received its full amount of twist, and immediately before the spindles commence "winding on." *Patent abandoned.*

55. J STENHOUSE. *Improvements in rendering certain substances less pervious to air and liquids.* Dated Jan. 8, 1862.

This consists in the use of paraffine for rendering leather, thread, cord, ropes, and textile fabrics composed of cotton, linen, or wool, &c., less pervious to air and liquids. *Patent completed.*

56. H. BESSEMER. *Improvements in the machinery and apparatus employed in the manufacture of malleable iron and steel.* Dated Jan. 8, 1862.

This consists in certain combined arrangements, whereby the steam employed for forcing air is generated by means of the heat escaping from the reverberating furnaces used in melting the iron to be converted. Also in the opening and closing of the passage conducting air into the connecting vessels, by means of the rotatory action of such vessels acting on a suitable valve. Also in the employment of several separate tuyer boxes attached to the under side of converting vessels, in which the air is forced vertically upwards through the molten metal. Also in the use of tuyer boxes, with sepa-

rate compartments for the several tuyers employed. Also in giving rotatory or semi-rotatory motion to converting vessels that are supported on fixed standards or foundations by means of hydrostatic force. Also in employing a pair of converting vessels so placed in regard to each other that the flame and splashes emitted therefrom shall be projected in opposite directions, the said vessels being capable of discharging the converted metal into a ladle placed between them. Also in the use of chimneys, with an open space beneath them for giving access to converting vessels employed in the production of malleable iron or steel, by forcing air through the fluid metal. Also in the use of two converting vessels with separate chimneys, and one hydraulic casting crane, grouped together as shown in the drawings. Also in the use of hydraulic cranes in casting malleable iron or steel, as described. There are various features included in the specification. *Patent completed.*

57. W. BRADSHAW. *Improvements in watches.* Dated Jan. 8, 1862.

This relates to a novel arrangement of the works for actuating a centre seconds wheel and hand. By this improvement the centre seconds hand is mounted on a pivot, and is carried over the other handles without the necessity of using the extra wheel which is usually used for this purpose in watches provided with a centre seconds hand. The power for actuating the centre seconds hand is gained from the third wheel, and is carried out by two extra wheels and three pinions; one of the wheels is on the centre seconds shaft, and the other is an intermediate wheel which actuates the fly pinion. The second power is directly connected with the independent seconds hand being attached to the same arbor or shaft that carries the seconds hand. For this purpose there is an extra power or spring enclosed in a box or collet on the seconds hand shaft, and on this same shaft is a pinion which gears into and is driven by the third wheel. *Patent completed.*

58. H. COOK. *An improved mode of and apparatus for propelling by the agency of electricity.* Dated Jan. 8, 1862.

The patentee claims the application of the tractive power of electric coils to cause an armature of iron constructed in the form of a hollow vessel casing carriage (made to contain articles of various kinds) to pass along a continuous line of rails placed within and extending throughout series of tubular electric coils, as herein set forth. *Patent completed.*

59. C. W. SIEMANS. *Improvements in the means and apparatus employed for insulating and protecting telegraph-conducting wire, and in apparatus for working the same.* (Partly communicated.) Dated Jan. 9, 1862.

Here, according to one part of the invention, the patentee forms the conductor either of a solid metal wire, or of a strand of two or more wires; or he sometimes first forms a strand of seven equal-sized wires, and then winds into the said helical recesses formed between these wires six other conducting wires of a smaller diameter, so as to cause the form of the complete conductor to approximate to that of a cylinder, which form would present the least surface for induction for a given sectional area. He causes the conductor to pass through a vessel containing either a compound of gutta percha, resin, and Stockholm tar, in a heated or semi-fluid state. The wire or strand of wires passes into and out of the vessel through holes or dies formed in the sides of the same. The conducting wire is next passed through a bath of cold or iced water, then passed round a series of rollers or reels so as to harden the coating; it is then coated with india rubber, and finally with gutta percha. In making joints in the india rubber covering of the conductor, he overlaps the uncovered part with india rubber strips, and completes the formation of the joint in a specially-constructed apparatus. *Patent completed.*

60. J. SMITH and S. WELLSTOOD. *Improvements in cooking stoves and ranges.* Dated Jan 9, 1862.

This invention is not described apart from the drawings. *Patent completed.*

61. J. BRUNT. *Improvements in gas meters.* Dated Jan. 9, 1862.

This consists, first, in the use of two floats attached to the valve stem, and having a common vertical movement, the box containing the floats being divided into two parts or chambers by a partition descending under the surface of the water between the two floats, one of these parts or chambers receiving the inlet gas before its passage into the drum of the meter, whilst the other chamber is in communication with the outlet gas which has passed through the drum of the meter. By this arrangement, a depression in the level of one chamber always corresponds to a nearly like elevation of level in the other chamber, so that the position of the floats or compound float is but slightly changed by the variations of level in the two chambers, whereby the inlet valve can be adjusted with precision. In draining off the overflow water from the syphon-pipe the patentee makes use of a plug or screw to which a rod is attached, on the upper part of which a weighted lever is supported; on withdrawing the plug for the passage of the overflow water, this weighted lever depresses the float, which, bringing the valve home on its seat, intercepts further passage of gas until the plug is returned to its former position. *Patent completed.*

62. T. A. WESTON. *A new or improved multiplying gearing for transmitting and multiplying power, which said gearing may be applied to cranes, windlasses, capstans, and presses, and to other purposes where it is required to transmit and multiply power.* Dated Jan. 9, 1862.

We cannot here devote space to the details of this invention. *Patent completed.*

63. D. WILSON. *Improvements in machinery for pulping and preparing coffee.* Dated Jan. 9, 1862.

For the purposes of this invention an annular rotating rubbing surface is used, together with another, and by preference a fixed or stationary, annular rubbing surface placed either above or below it. The rotating rubbing surface is mounted on and carried by an upright axis, to which rotatory motion is communicated in any suitable way. The annular rotating surface moves in a horizontal plane, and the other annular rubbing surface is fixed in a plane parallel to it; above these rubbers is fixed a conical hopper, into which the coffee berries are to be placed, and a constant supply of water applied to them. In order that the berries and the water may descend from such hopper so as to be fed in all directions between the annular rubbers, there is around the inner edges of the rubbers, and within the hopper, a cone, the apex of which is upwards; the lower or delivering part of the hopper is thus formed into an annular passage, corresponding in dimensions with the inner edges of the rubbers; hence, as the coffee berries and water descend in the hopper, they pass in between the annular rubbing surfaces at their inner edges, and are rubbed between such surfaces, and pass out at their outer circumference, and the matters as they pass out from between the rubbers are received in a trough. *Patent completed.*

64. H. CHARVET. *Improvements in the spinning of cotton and in its various applications.* Dated Jan. 9, 1862.

Here the inventor, after he has passed the raw cotton or cotton wool through the beater or scutcher, dyes it of various colours, according to the effect or design he intends to produce; he then repasses it by the opener and the lap scutcher, on leaving which he submits it to the carding machine, then to the combing machines, and then to the shifting or bobbin frame. The mode of preparation will vary according to the lighter or deeper mixture, or more or less apparent design to be produced. *Patent abandoned.*

65. D. WILSON. *Improvements in hydraulic presses.* Dated Jan. 9, 1862.

This refers to preparing seeds or fatty and other substances in order to express oil therefrom; and, where it is desirable, first to form the substances into circular cakes to be placed in a suitable press to have the oil expressed therefrom, such preparatory process is performed in a press having a long cylinder with a ram or piston capable of being moved by hydraulic or other power from the lower to the upper end thereof, the substances to be pressed being supplied in regulated quantities, in a manner which we cannot here describe in detail. *Patent completed.*

66. J. H. TATUM and W. J. WILLIAMS. *Improvements in the manufacture and structure of wicks, and in the application of the same to the manufacture of candles.* Dated Jan. 9, 1862.

Here the patentees construct a new form of wick by one single operation of a machine (not described apart from the drawings) resembling in its exterior the ordinary three-strand braiding machine, but totally different in its interior. They introduce into one of the shafts a hemp or flax cord or string, and into the other a soft cotton or woollen cord or string, which cords, being taken up in the braids in the form of a core, a wick is formed of great capilarity. The cords or cores, and a portion of the cotton forming the strand in the braid, are steeped in an aqueous solution containing chemicals that will dissipate the ash. *Patent completed.*

67. R. A. BROOMAN. *Improvements in apparatus for carburetting and burning gas.* (A communication.) Dated Jan. 9, 1862.

The patentee claims, first, the employment in apparatus for carburetting and burning gas of a wick and burner, the said wick being protected and capable of absorbing and raising the carburetting liquid, as described. Second, the employment of a current of air between the carburettor and the tube leading to the burner, as described. Third, the employment of two currents of gas, one of which is carburetted as described, while the other is ordinary coal gas and passes direct to the burner, where both currents are consumed together. The apparatus employed is not described apart from the drawings. *Patent completed.*

68. B. THOMPSON. *Improvements in ordnance and fire-arms, and in projectiles to be used therewith.* (A communication.) Dated Jan. 9, 1862.

This consists in forming the barrels of fire-arms and ordnance with ribs or guide ways down the length of the inside of the tube, in a line parallel with its longitudinal axis, and in making the breech end of such ordnance or barrels to contain a charge or exploding chamber of peculiar form, to suit the projectile described; and also in the form of projectile which is specially adapted for use, with the description of ordnance or barrels aforesaid. The invention is not described apart from the drawings. *Patent completed.*

69. H. BARBER. *Improvements in safety lamps.* Dated Jan. 9, 1862.

One object of this invention is to render it impossible for the workman to remove the lights from the lamp, or even to attempt to do so, without detection. This is effected by attaching to some fixed part of the lamp a piece of thin steel, or other suitable brittle substance, in such a manner that the lower part of the lamp cannot be removed from the upper part or gauze protector without breaking the brittle substance. A convenient way of doing this is to attach the piece of steel, &c., to the lower part of the lamp, so that when any attempt is made to unscrew the bottom part, an arm, pin, or other projecting piece will be brought against this brittle piece, and will break it off. As the workman will be unable to supply or replace the defective part, this will at once show that the lamp has been tampered with, and the man will be dealt with accordingly. The inventor also proposes to adapt an extinguishing tube to the wick holder, and by raising this extinguisher the light will be put out. *Patent abandoned.*

70. A. R. LE M. DE NORMANDY. *Improvements in fixing tubes in tube plates.* Dated Jan. 10, 1862.

This consists in passing the extremity of the tubes through plain flat plates perforated with holes somewhat larger than the said tubes, so that the two extremities of each tube may protrude a short distance through the said perforated plates. A ring (or more, if required) of vulcanised india-rubber is then stretched round the ends of the tubes which thus protrude beyond the perforated plates, so as to grip them tightly; or else a "gasket" smeared with red lead, or some other analogous material, is wound round the ends of the said tubes, and a pressing plate, that is to say, a flat plate perforated with holes also somewhat larger than the tubes, and corresponding with those of the perforated plates first-mentioned, is put over the vulcanised india-rubber rings, gasket, &c., so that the said vulcanised india-rubber rings, &c., round the said tubes, being thus situated between the flat surfaces of the tube plates and pressing plates, may, by bolting the said plates together in the usual way, be tightly squeezed between them, and thus prevent any leakage round the extremities of the said tubes, and thus obviating the necessity of using glands, collars, or "ferules," or of forcibly expanding the tubes in the tube plate as heretofore, so that when it is found necessary to replace one or more of the said tubes, it may be done simply by unbolting the two plates between which the said tubes are grasped by the vulcanised india-rubber or gasket. *Patent completed.*

71. J. CARTER. *A new or improved draining plough.* Dated Jan. 10, 1862.

The patentee claims a draining plough in which a series of balls or drags, connected with the foot of a coulter or knife, are made in combination with the said coulter or knife, to form cylindrical or pipe-like drains below the surface of the land. *Patent completed.*

72. R. JOHNSON. *An improved composition for coating the bottoms of iron ships to prevent them fouling and other purposes.* Dated Jan. 10, 1862.

This composition consists of mercurial or blue ointment (a mixture of mercury and fatty matter), arsenic, and black lead, in combination with drying oil, oil paint, or common coal tar, or black varnish. The patentee prefers to use the ingredients in about the following proportions, say, 2 lbs. by weight of the mercurial ointment, 2 lbs. by weight of powdered arsenic, with 6 lbs. by weight of black lead in powder to one gallon of coal tar, or black varnish, or paint oil, or oil paint, or other suitable vehicle, coal tar or black varnish being preferred. He thoroughly amalgamates the several ingredients by the use of a mill or pestle and mortar, or in any other convenient way. He prefers to apply this composition over a coating of common coal tar or black varnish. *Patent completed.*

73. M. WIGZELL. *An improved double-acting ventilator for railway carriages and other carriages and compartments.* Dated Jan. 10, 1862.

This consists of two chambers, with or without inner shutes of wire work or perforated divisions, for directing or dispersing the air, and for preventing the rain from entering the carriage or compartment, and it has an external opening in each chamber, so that the fresh air is admitted through one external opening into the inner space or spaces in the apertures, and then into the carriage, room, or other compartment to which it may be applied, and the hot or impure air is made to pass out from the carriage or other compartment through the outer chamber or space in the ventilator, by being assisted in its outward passage by the suction caused by the ventilator or apparatus passing through the air, or by the air rushing past the opening through which the hot or impure air passes out from the carriage or other compartment to which the ventilator is affixed. *Patent completed.*

74. J. MOORES. *Improvements in obtaining motive power.* Dated Jan. 10, 1862.

Here the inventor arranges two cisterns above a wheel, the said wheel being constructed with exterior buckets, or similar contrivances, so that, as the water descends from one of the cisterns, it gives motion to the wheel. The two cisterns may be connected by any ordinary means, each of them having a tap or other means of outlet, one to give direct motion, and the other a back motion when necessary. The said cisterns are to be filled, in the first instance, either by hand or power. He fixes on the main shaft of the said water-wheel a toothed-wheel, to work or give motion to two other toothed-wheels, each of which works a pump by means of connecting levers, the said pumps raising or lifting the water which falls from the wheel into the aforesaid cisterns, thus using the same water continuously to give motion to the wheel, which motion may be conveyed to any convenient shaft, crank, or wheel, acting as the principal prime mover. *Patent abandoned.*

75. J. OATES. *Improvements in washing machines.* Dated Jan. 10, 1862.

This consists of a tub or cylindrical vessel mounted centrally on the top of a vertical spindle or pivot, supported in a suitable framing. On the spindle is a cog wheel, into which two racks gear, one on each side of the spindle. One end of each rack is connected respectively to two hand levers, which are actuated alternately in opposite directions, thereby giving partial rotary motion to the tub or vessel. A circular lid or disc fits loosely within the tub, which is also mounted centrally on the bottom end of another vertical spindle, which is supported by a suitable fixing on a portable rail placed across the tub, but clear thereof, and attached to the framing, in which fixing the said spindle is free to rotate and slide up or down. A stud or arm is fixed in the top of the lid, at a suitable distance from the centre, to which is attached a rod connected to one of the hand levers, by the action of which partial rotary motion is given to the lid in a contrary direction to the motion of the tub. The under side of the lid, and the upper side of the tub bottom, are provided with ribs or projections. *Patent completed.*

76. H. LARVILL. *The hardening of chalk for building purposes.* Dated Jan. 10, 1862.

Here the inventor first cuts the chalk, after it has been cut into the required forms, and then immerses it, under pressure or otherwise, in a saline mineral solution; and after this has become thoroughly imbibed into the pores of the chalk, he places it in another solution capable of decomposing the first, and thereby depositing in the pores of the chalk a hard insoluble mineral chalk. He prefers to employ as the first solution either silicate of potash or silicate of soda, or tungstate of potash or tungstate of soda; and for the second solution, chloride of calcium; but he does not confine himself to the use of these salts. *Patent abandoned.*

77. W. H. PREECE. *Improved apparatus for signalling upon railways.* Dated Jan. 10, 1862.

Here the patentee proposes to assimilate the signals of telegraphic instruments to the visible hire signals used upon, and familiar to all persons on the working of, the railway. This he effects by adapting to telegraphic instruments a semaphore arm or disc, or other indicator, as the case may be, which he operates by electro-magnetic power. *Patent completed.*

78. L. PETRE and E. S. TUCKER. *The application of velvet, plush, leather, American cloth, oil-cloth, and other such like substances, alone and in combination with other materials for advertising boards, show cards, window tickets, and all such uses.* Dated Jan. 10, 1862.

Here the inventor takes velvet, plush, cloth, leather, &c., and, by a machine, or otherwise, coats the back of the fabric with a thin solution of india rubber, gutta percha, gum shellac, and other gums or adhesive substance. The material is then passed a second time through the machine, in order to increase the adhesive coating to the required thickness. The letters or devices are then cut out of the material first described, by hand or machinery, and are made to adhere by heat or otherwise to grounds, such as wood, card, oil-cloth, &c. *Patent abandoned.*

79. J. KENYON and A. HORN. *Improvements in railway signalling by electricity, and in the arrangement of apparatus for that purpose.* Dated Jan. 10, 1862.

This consists in laying down on lines of railway a system of telegraph wires and terminals, acting in conjunction with batteries of signalling apparatus carried by the trains, in such manner that each passing train shall have an indication of its presence, if within, say, two or three miles, whereby to indicate that the line is interrupted, and shall also, on exceeding that limit, remove the indication of its presence, thereby denoting the line clear to succeeding train. *Patent abandoned.*

80. W. CLARK. *Improvements in apparatus for generating and applying steam as a motive power.* (A communication.) Dated Jan. 10, 1862.

We cannot here give space to the voluminous details of this invention. *Patent completed.*

81. T. RAMSAY. *Improvements in the manufacture of coke.* Dated Jan. 11, 1862.

This consists in reducing large or small coal to the finest state of powder before converting it into coke. The patentee prefers to use such bituminous or coking coal, and he guides such coal under edge stones, horizontal stones, or rollers, to a powder. He finds horizontal stones similar to those used in grinding flour. This finely-ground coal is then put into the coke ovens and burnt in the usual way. *Patent completed.*

82. H. CHARLTON. *Improvements in the manufacture of certain kinds of shoes for mules and horses.* Dated Jan. 11, 1862.

This consists in shaping by rolling bar iron, from which shoes for horses and mules are manufactured, instead of shaping the said iron by hand forging, as is ordinary, and cutting or piercing the whole of the rectangular holes, or more than one of them, in the partially made shoes at one operation by the use of a direct acting press. *Patent completed.*

83. J. WHITE. *Improvements in lubricating, or oil cans or oil feeders, and in the mechanical arrangements for regulating the flow of oil therefrom.* Dated Jan. 11, 1862.

This relates to a can in which the movable top or cover has a top lining of leather, cork, &c., so that by temporarily securing the top, an air-tight and liquid-tight cover will be obtained. The patentee applies certain internal arrangements for regulating the flow of oil. *Patent completed.*

84. L. MACKIRDY. *Improvements in apparatus for reburning animal charcoal.* Dated Jan. 11, 1862.

This invention consists of a series of trays arranged spirally and vertically over a fire-place, or in a flue, the covers of the trays being perforated to allow of the gases evolved in the burning passing readily off from the charcoal. The trays communicate at top with a hopper, in which the charcoal to be reburnt is placed, and at bottom the trays open into a spout furnished with slides, through which the reburnt charcoal enters a closed receiver, in which the charcoal is allowed to cool without contact with the atmosphere. *Patent abandoned.*

85. T. SCOTT. *Improvements in steam-engines.* Dated Jan. 11, 1862.

This invention consists of new arrangements, hereinafter described, of combined or high and low-pressure cylinder engines. The inventor places his cylinders one over the other, that is, the small, or high-pressure cylinder over the large cylinder; or he places them side by side, according to the work the engines are intended to perform, that is, whether they are to be horizontal or vertical. The large cylinder is furnished with two piston-rods, united by a cross-head, and this cross-head by links to one end of an oscillating beam. The high-pressure cylinder has one piston rod only, and this, through a connecting rod and parallel motion, is connected to the opposite end of the oscillating beam. The ports or passages for the steam are from top to top, or from bottom to bottom, of the cylinders, and while the piston rod of the high-pressure cylinder is proceeding in one direction, the piston rods of the large cylinder move in the opposite direction, and cause the beam to vibrate or oscillate. The main connecting rod to the crank shaft is attached to the centre of the cross-head, and the power from the high-pressure cylinder is transmitted through the oscillating beam and links, and through the cross-head to the main connecting rod. *Patent completed.*

86. W. WILKINSON. *Improvements in ornamenting and decorating metals, glass, porcelain, parchment, and other skins, and in the material and ingredients employed therein; also in protecting silver and gold on said materials, and on surfaces or plates of glass and metal combined, applicable to works of art, furniture, jewellery, and other articles of a useful and ornamental character.* Dated Jan. 11, 1862.

This consists, 1, in an improved mode of protecting on or between sheets of glass, or on metals, figured designs, pictures, prints, engravings, &c., either embroidered or plain, or if necessary gilded or silvered, or otherwise ornamented, and rendered transparent or not, according to the purpose for which it is designed. 2, in gilding or silvering, or applying other metals to designs on paper and other fabrics and materials by printing the same in a lithographic or other suitable press, or by other means; and further, in ornamenting the paper and other fabrics and materials with suitable dye, colours, or inks, so as to produce an ornamental design protected by being placed upon or between plates of glass or glass and metal combined, and when thus ornamented is well adapted for pictures, windows, window blinds, pannellings to rooms, doors, ceilings, cornices, &c. *Patent abandoned.*

87. A. C. SOUTHBY. *Improvements in the preparation of pulp for paper-making.* Dated Jan. 13, 1862.

This consists in a method of washing the soluble matter from paper stuff to prepare the same for bleaching, or for the manufacture of brown paper, and consists, chiefly, in the slow and continuous percolation of water or other liquids through the paper stuff when packed into a dense mass. Also, in a method of applying bleach liquor in the preparation of pulp for paper making, such consisting, partly, in the slow and continuous percolation of bleach liquor through the paper stuff when packed into a dense mass, and partly in the use of partially exhausted bleach liquor in commencing the process of bleaching. Also, in a method of washing out of paper stuff, after it has undergone the process of bleaching, the bleach liquor and the colouring matters which have been rendered (by the application of the same) soluble in water, or in solutions of alkalies or acids, such method consisting chiefly in the slow and continuous percolation of water or solutions of alkalies or acids through the paper stuff when packed in a dense mass, and after it has undergone the improved method of bleaching above described, or any other method of bleaching. *Patent abandoned.*

88. J. M. ROWAN. *Improvements in the manufacture of iron and steel.* Dated Jan. 13, 1862.

This consists of improved modes or means of introducing into fluid iron for the purpose of removing such impurities as sulphur, phosphorus, and silica, gaseous matters, such as chlorine, hydro fluoric acid, and others, depending on the particular action desiderated. And in carrying out the invention the said gases, being produced in any convenient manner in separate receivers, are afterwards made to enter the melted metal by being forced in after their production by means of pumps or other suitable means, or by being produced in closed vessels in such a way as to have the pressure requisite for their introduction into the melted metal. *Patent abandoned.*

89. T. and C. GILBERT and T. HADDON. *An improvement or improvements in the manufacture of swivels for guns and in machinery to be employed in the said manufacture.* Dated Jan. 13, 1862.

The patentee claims, 1, making the blanks from which the said swivels are made by forming a knob or head on each end of a rod of iron, or a piece of iron, by upsetting or compressing a portion of the ends of the said rod or wire in the direction of its length, from which knobs or heads the flat disc-like ends of the services are formed; 2, the machinery or tools described (with reference to the drawings) for upsetting or compressing the ends of the rod of iron, or piece of iron-wire, so as thereby to manufacture swivel-blanks. *Patent completed.*

90. F. C. WARLICH. *Improvements in the manufacture of artificial fuel.* Dated Jan. 13, 1862.

The patentee claims, 1, the application of the gases evolved during the distillation of coal to the heating of carbonizing ovens, in which block-fuel is subsequently baked; 2, the application of the gases evolved during the torrefication of coal to the heating of the torrefiers, retorts, and carbonising ovens; 3, the collection of coal-tar and other distillates during the process of torrefying bituminous coal for the manufacture of black fuel. *Patent completed.*

91. T. and M. SOAR and J. BELSHAW. *An improved knocker to be attached to doors, shutters, or other parts of premises to which the same may be applicable, and applicable also for the reception of letters and other documents.* Dated Jan. 13, 1862.

This consists of an arrangement and combination of apparatus in which is used a plain or ornamental plate of cast iron or other metal or material, the upper end of which is made in the form of a label or scroll, upon which a name or number may be engraved, or otherwise delineated. Below the label or scroll is a stud or studs, which forms or form part of the hinge of the knocker, and which is secured to it by a pin or rivet. The back of the knocker forms a plug and rivet, which closes a slit in the plate lying below the stud. Below this slit is a projection near the bottom or lower end of the plate, upon which the knocker falls; and, where required, a hole may be drilled through the projection, and a wire passed through it, having one end tapped and screwed into the lower end of the knocker; in which case, when the knocker is raised for inserting a letter or other document, it will, besides knocking the door, also ring a bell, the other end of the wire being connected to another wire or lever for that purpose. A receptacle for the letters or other documents may be added, the same being composed of wood or suitable material. *Patent completed.*

92. J. PARKER and J. and B. WELLS. *Improvements in steam-engines, boilers, furnaces, and apparatus in connection therewith or applicable thereto.* Dated Jan. 13, 1862.

The specification of this invention comprises novel arrangements for effecting a more efficient force of steam when applied as a motive power, and for economising the working of steam-engines, thereby effecting a saving of fuel, and a better combustion of the gases. We cannot here give the details. *Patent completed.*

93. W. E. GEDGE. *Improved means or apparatus for gaining or acquiring motive power.* (A communication.) Dated Jan. 13, 1862.

This consists of a trough partially filled with water. In this trough is made to rotate (by cog-wheels and pinions, pulleys, or any suitable gearing), a wooden or metal drum or cylinder, supported on a horizontal shaft, and having on its outer surface a number of sacks or pockets (of leather, caoutchouc, or some woven or other suitable fabric), into each of which enters a couple of tubes, the other ends of which are socketed on the drum, and provided with a small toothed wheel, the rotation of which opens or shuts a tap placed in the tube accordingly as the motion sets in one direction or the other. As the drum rotates, it works a pair of bellows, injecting into each pocket, as it passes beneath the water, sufficient air to fill and swell it out, giving it a tendency to rise to the surface of the liquid, where the air is permitted to escape, and the pocket collapses to be again inflated, when, by the continued rotation of the drum, it again passes beneath the water. It will be readily understood that the pocket, being filled with air when under water, naturally endeavours to rise to the surface of the liquid, and thus cause the drum to continue its rotation at more or less speed. *Patent abandoned.*

94. F. W. MARX. *Improvements in the manufacture of cups, bowls, saucers, and other dished articles and cases.* (A communication.) Dated Jan. 13, 1862.

This invention consists in manufacturing cups, bowls, saucers, and other dished articles, as also cases of leather, velvet, silk, and other like materials, as hereafter described. The inventor cuts out from a skin or other material two discs, and, if desired, cements a figure on the back of each of the discs, paper, muslin, cloth, or other strengthening material. He applies a stiffening agent, such as shellac. Each of the discs, alone or strengthened, is afterwards stamped in relief, or in intaglio, with any pattern desired; the two discs thus prepared are placed over or one within another, and the edges are closed and ornamented by a metal moulding or not, according to the nature of the article. For cases the stamped discs are superposed and united by a hinge at back and snap in front. *Patent completed.*

95. HENRY SCHOTTLANDER. *Improvements in albums for containing photographic and other pictures.* Dated Jan. 13, 1862.

This invention consists in so forming the leaves of albums that the picture or pictures, together with part of the leaf holding the same, may be placed and held at an inclination, so as to obtain the most suitable light for viewing the pictures. The inventor applies on each side of every leaf, or on one side only, a frame for holding one or two pictures, and unites it at one side or end only; and he makes a tongue or frame in or on the holding frame. When the album is closed, or when the leaves and pictures are in their ordinary position, the holding frames, pictures, and tongues do not protrude beyond the thickness of the leaves. When the album is opened, and any picture is to be viewed, the holding frame is raised, and the tongue or back frame is protruded outwards, and the frame, resting partly upon it, is maintained inclined. If desired, pictures may be held in the leaves which are covered by the holding frames, and which can only be seen when such frames are raised. Again, instead of the tongue or supporting frame before mentioned, he sometimes forms the support by bringing a piece of cardboard or other suitable material to the top of the holding-frame, which is pushed outwards for supporting the holding-frame, and which is folded inwards and under the holding-frame, when the pictures are not required to be raised to be viewed. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated March 11, 1862.

652. J. Nadal, mechanist, 14, Brook's Market, Holborn. An improved portable fountain for water or other liquids.

Dated March 17, 1862.

728. A. S. and A. R. Stocker, Wolverhampton, manufacturers. Improvements in the manufacture and construction of metal boot heels and tips and horse shoes.

Dated March 31, 1862.

887. M. A. F. Mennons, 39, Rue de l'Echiquier, Paris. Improvements in the manufacture from vegetable product of glucose or fermentable sugar. (A communication.)

Dated April 14, 1862.

1074. R. A. Brooman, 166, Fleet Street, patent agent. Improvements in carriages for transporting loads on railways, common roads, and other surfaces. (A communication.)

Dated May 20, 1862.

1520. M. A. F. Mennons, 24, Rue du Mont Thabor, Paris. Improved processes for the conversion of amylaceous matters into saccharine and other useful products. (A communication.)

Dated May 22, 1862.

1541. J. H. Perry, 72, Piccadilly, gentleman. An improved method of curing diseases of the human body by magnetism.

Dated May 29, 1862.

1612. P. Boisset and B. Antognini, New York. Improvements in the manufacture of boots and shoes.

1613. H. Boetius, Great George Street, C.E. A new mode of cooling (refrigerating) hot liquids, and condensing steam.

Dated June 3, 1862.

1669. T. L. Scowen, Allen Road, Stoke Newington. Improvements in indicating time and accent in music.

Dated June 5, 1862.

1693. J. E. Moiroux, Windmill Street, Tottenham Court Road. A new compound for protecting and preserving the polish, polished, and other surfaces of metals, woods, skins, and paper, and for rendering all woven, textile, and other fabrics water and weather proof

Dated June 11, 1862.

1734. J. Shand and S. Mason, engineers, 245, Blackfriars Road. Improvements in the construction of steam boilers.

1738. W. Holland, Adelphi Mills, Salford, cotton spinner. Certain improvements in carding engines.

Dated June 12, 1862.

1751. H. S. Firman and W. J. Williams, 73, Great Suffolk Street, Southwark. Improvements in lamps, more particularly designed for burning paraffine or coal oil and other hydro carbons of different grades, or any combustible material used for obtaining light. (A communication.)

Dated June 16, 1862.

1777. C. E. Courtillier, 184, Boulevart Magenta, Paris, physician. Improved inhaling and saturating apparatus.

1779. J. F. Allan, ironfounder, Glasgow. Improved furnace arrangements to prevent smoke and economise fuel.

1781. J. Evans, Hyde, Cheshire, overlooker. Improvements in self-acting mules.

1783. H. Bright, Woodford, Essex, gentleman. Improved apparatus or arrangements for screening fires in stoves and grates with the view to avoid accidents.

Dated June 17, 1862.

1785. S. H. Huntly, 50, Upper Baker Street, Regent's Park. Improvements in the construction of furnaces for effecting the more perfect combustion of the fuel.

1786. A. Crestadoro, 19, Great Ormond Street, Queen Square. Improvements in obtaining and applying motive power from rarefied air and from aeriform fluids.

1787. J. Hunt, Birmingham, brassfounder. An improvement or improvements in bronzing or colouring articles of copper or alloys of copper.

1789. A. W. Makinson, Westminster, C.E. Improvements in locomotive and stationary engines.

1791. A. Pringle, Gloucester Crescent, Camden Town. Certain improvements in locks.

1793. S. Varley, Sleaford, Lincolnshire, engineer. Improvements in reaping machines.

Dated June 18, 1862.

1799. J. Warren, Maldon, Essex, implement manufacturer. Improvements in ploughs.

1801. W. E. Newton, 66, Chancery Lane, C.E. Improvements in electrical brushes. (A communication.)

Dated June 19, 1862.

1803. J. L. Smith, 18, St. John's Square, Clerkenwell, clock manufacturer. A universal fire alarum with discharging apparatus.

Dated June 25, 1862.

1865. A. Bayley, Liverpool, oil merchant. Improvements in lamps.

Dated June 26, 1862.

1875. T. R. Tebbutt, Manchester, soap manufacturer. Certain improvements in the manufacture of soap, soda, and other material employed for the purpose of washing and cleansing.

1877. J. B. Coquatrix, Rue Folie Mericourt, Paris. Improvements in weaving carpets, tapestry, and similar fabrics, and in apparatus for the same.

1879. J. H. Johnson, 47, Lincoln's Inn Fields, gentleman. Improvements in the construction of electro-voltaic plate work for medical and other purposes. (A communication.)

1880. J. H. Johnson, 47, Lincoln's Inn Fields, gentleman. A new composite fluid to be used for illuminating purposes. (A communication.)

Dated June 27, 1862.

1881. A. Anderson, blacksmith, St. John's, New Brunswick. Improvements in apparatus for steering ships or other vessels.

1882. J. Watson, 10, Old Bailey, City, printer. Improvements in printing machines and apparatus connected therewith for printing from letter-press forms.

1883. C. Cochrane, Ormesby Iron Works, Middlesbro'-on-Tees. Improvements in the manufacture of aluminate of soda and potash.

1885. C. Cochrane, Ormesby Iron Works, Middlesbro'-on-Tees. Improvements in the manufacture of iron.

1887. W. Owen, Coventry, designer. The manufacture of woven tickets of silk, cotton, or wool, or mixture of those materials, for the purpose of marking or advertising goods.

1889. A. H. Martin, Buttershaw, near Bradford, Yorkshire, mechanic. Improvements in means or apparatus employed in weaving.

1890. I. Holden, Bradford, Yorkshire, machine wool comber. Improvements in means or apparatus for preparing and combing wool and other fibrous materials.

1891. A. A. Croll, Coleman Street, City, engineer. Improvements in the treatment of ammoniacal liquor of gas works.

1892. D. L. Banks, engineer, 17, Gracechurch Street. A new method of constructing a portablecovered coffer dam or apparatus for facilitating operations under the water, in the water, or out of the water, and apparatus connected therewith.

1893. D. L. Banks, engineer, 17, Gracechurch Street. A method of constructing a portable sectional dry dock, and apparatus connected therewith.

Dated June 28, 1862.

1895. T. King, Grafton, Warwickshire, farmer, and John King, Chadshunt, Warwickshire, farmer. Improvements in agricultural machines.

1896. C. Beslay, Rue Menilmontant, Paris, gentleman. Improvements in galvanizing or coating metals by electro-chemical agency, and in apparatus connected therewith.

1899. G. W. Belding, 7, King Street, Cheapside. An improved flexible-spring cloth or fabric especially adapted for the manufacture of ladies' skirts.

1900. C. Callebaut, 2, Rue Ste. Appoline, Paris. Certain improvements in sewing machines.

1901. J. Tatham, Rochdale, machine maker. Improvements in machinery or apparatus for preparing, spinning, doubling, and winding cotton, wool, and other fibrous materials.

1903. J. Webster, 142, Woodbridge Road, Ipswich. Improvements in the means of protecting steam boilers from incrustation.

Dated June 30, 1862.

1905. J. Wall, Liverpool, plumber, and T. Dodd, Liverpool, glass merchant. Improvements in taps for controlling the flow or passage of fluids.

1906. W. Thomas, Liverpool, carriage builder. Improvements in the running gear of four-wheeled carriages.

1907. J. Hartshorn, Mansfield Road, Nottingham, lace manufacturer. Improvements in the manufacture of lace.

1908. A. Byrnes, 5, Metropolitan Buildings, Mile End New Town, gun maker. Improvements in breech-loading fire-arms.

1909. W. E. Gedge, 11, Wellington Street, Strand. Improvements in looms for weaving. (A communication.)

1911. W. E. Newton, 66, Chancery Lane, C.E. Improved apparatus for picking or gathering cotton. (A communication.)

1913. T. Parker, Woodhouse Carrs, Leeds, dyer and stover. Improvements in tinting or dyeing fabrics composed of mixed animal and vegetable fibres.

Dated July 1, 1862.

1917. R. A. Brooman, 166, Fleet Street, patent agent. Improvements in the construction of blast furnaces. (A communication.)

1919. G. H. Birkbeck, 34, Southampton Buildings, Chancery Lane, engineer. Improvements in processes for the utilisation of certain refuse products resulting from the manufacture of iron, such processes being applicable to the treatment of other metallic or mineral substances. (A communication.)

1920. J. Greenhalgh, Hyde, Lancashire, mechanic, and J. Greenhalgh, Audenshaw, farmer. An improved diminishing valve, and also a water or steam escape apparatus to give alarm in case of fire, and to assist in quenching the same.

1921. T. Fellowes and H. Hemfrey, Spalding. Improvements in apparatus for elevating straw and other agricultural produce.

1923. W. E. Newton, 66, Chancery Lane, C.E. Improved machinery for washing wool. (A communication.)

Dated July 2, 1862.

1924. E. De Labastido, 43, Hart Street, Bloomsbury. A new method of manufacturing india-rubber articles by the simultaneous combination of pressure and vulcanisation. (A communication.)

1925. W. Porter, Fleetwood. Improvements in the manufacture of targets.

1927. J. Ellerbeck, Heywood, manufacturer. Improvements in looms for weaving.

1929. T. L. Atkinson, Stamford Street, Blackfriars Road, wharfinger. Improvements in the construction of stew pans and other such like cooking utensils.

1930. G. H. Hulskamp, Troy, New York, piano forte maker. Improvements in violins and other similar stringed instruments, and in guitars.

1931. J. Murray, Whitehall Place, solicitor. Improvements in portmanteaus.

1933. J. Crisp and J. W. Elliott, East King Street, South Shields. Improvements in apparatus for burning American rock oil, paraffine oil, oil of petroleum, and other inflammable oils, spirits, or essences.

1935. G. Bedson, Manchester, manager. Improvements in rolling wire and other rods or bars of metal.

Dated July 3, 1862.

1941. T. Edmunds, Seymour Place, Bryanstone Square, grocer. Improvements in preparing compressed fruits in cakes.

1943. J. Miles, Street, near Glastonbury, Somersetshire. Improvements in machinery for cutting out soles and other parts used in the manufacture of boots and shoes, and also parts used in the manufacture of other articles.

Dated July 4, 1862.

1944. S. Russell, 27, Shaftesbury Crescent, Pimlico. Improvements in stereoscopes.

1945. W. J. Cunningham, Everett Terrace, Victoria Dock Road, Essex, outfitter. Improvements in sewing machines.

1946. A. Drevelle, Manchester, merchant. Improvements in machinery or apparatus for laying cards or sheets of metal into woven or textile fabrics ready for the press, and also for folding, measuring, or stretching the said fabrics, paper, and other materials.

1947. S. Whitham, Wakefield, iron manufacturer. Improvements in the manufacture of iron and steel, and in the apparatus employed for that purpose. (A communication.)

Dated July 5, 1862.

1949. H. Rushton, 48A, Northampton Road, Clerkenwell. Improvements in covering crinoline steels.

1950. R. A. Brooman, 166, Fleet Street. Improvements in hollow plates for hydraulic presses. (A communication.)

1951. O. F. Byström, Stockholm, captain of artillery. An improved pyrometer.

1952. C. G. Hill, Commerce Square, High Pavement, Nottingham, lace manufacturer, and W. Jackson, engineer. Improvements in machinery or apparatus for producing ornamental patterns or figures and attaching them to lace or other fabrics.

1952. A. Warner, 31, Threadneedle Street. Improvements in preparing materials for and in purifying coal gas.

Dated July 7, 1862.

1957. T. Edwards, Liverpool, gas engineer. Improved movement for the indices for gas, water, and other fluid meters.

1959. J. P. Booth, Cork, feather purifier. Improvements in the manufacture of feather beds, quilts, bolsters and pillows.

Dated July 8, 1862.

1960. W. Spence, 50, Chancery Lane. Improvements in telegraphic apparatus. (A communication.)

1962. C. B. Gruner, 25, Alfred Street, River Terrace, Islington. Improvements in photographic apparatus.

1968. J Bourke, Her Majesty's 29th Regiment of Foot, Curraghleagh, Clanmorris, Ireland. Improvements in military accoutrements.

Dated July 9, 1862.

1972. T. C. Gibson, Ramsey, Isle of Man, ship builder. Improvements in the construction of ships and vessels for the purpose of carrying and warehousing petroleum, palm oil, and other oils or inflammable fluids.

1974. H. S. Pontifex, Banbury, brewer. Improvements in apparatus for distributing water applicable to cleansing casks or other vessels, or for other purposes.

1976. C. F. W. Rust, London Wall, merchant. Improvements in concertinas and other wind instruments of that class. (A communication.)

1980. T. Green, Smithfield Iron Works, Leeds, and R. Mathers, 2, Victoria Street, City. Improvements in steam boilers.

1982. J. O. Butler, Kirkstall Forge Company, near Leeds, engineer. Improvements in steam hammers and in framings therefor.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

1971. J. M. Gille, 24, Rue du Mont-Thabor, Paris, Knight of the Imperial Legion of Honour. An improved calendar inkstand. *Dated July* 9, 1862.

1990. E. Townsend, Massachusetts, U.S. A new and useful invention for making nails, and driving such nails into the sole of a boot or shoe. (A communication.) *Dated July* 10, 1862.

2006. M. A. F. Mennons, 24, Rue du Mont-Thabor, Paris. Certain improvements in vessels mounted as floating batteries. (A communication.) *Dated July* 12, 1862.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

612. J. Fowler, D. Greig, and R. Noddings. Cultivating or tilling land.
619. A. W. Williamson. Generating steam.
633. F. N. Gisborne and H. Wickens. Indicating the presence of fire damp or choke damp in mines.
648. J. T. Callow. Mining or lifting machines.
652. J. Nadal. Portable fountain.
658. C. Hall. Cultivation of the soil by steam.
670. J. Johnson and S. Morris. Steam boilers.
671. W. Conyers. Currying leather.
674. A. M. A'Beckett. Railway signal apparatus.
691. M. Henry. Stuffing boxes. (A communication.)
692. R. A. Brooman Measuring and regulating the flow and pressure of gas. (A communication.)
699. R. Schomberg and A. Baldamus. Purifying illuminating gas.
704. G. Bennett. Coating and covering wrought iron.
705. G. H. Sanborn. Gas regulators. (A communication.)
706. L. Gabler and M. Zingler. Manufacturing articles from ivory and bone.
708. A. J. Paterson. Electric telegraph cables.
709. M. A. Muir and J. McIlwhain. Railway sleepers and chairs.
711. A. and W. Coles. Trusses for cases of hernia.
714. C. N. Kottula. Manufacture of combined soaps.
715. G. B. Pettit. Heating water and other liquids.
716. J. Smadja. Bustles and crinolines.
718. J. Hunter and R. Scott. Reaping machines.
721. S. N. de la Haye de Barbezière. Horse shoe.
723. G. Hamilton. Tumbler locks.
724. J. Robey. Manufacturing and refining sugar.
725. W. Pickstone. Manufacture of piled fabrics.
728. A. S. and A. R. Stocker. Manufacture and construction of metal boot heels and tips and horse shoes.
730. W. B. Lord and F. H. Gilbart. Raising, lowering, and releasing ships' boats or other heavy bodies.
734. J. and W. Weems. Regulating the discharge of fluids.
738. G. T. Bousfield. Cranks. (A communication.)
746. M. A. Mennons. Cooling and filtering apparatus. (A communication.)
758. S. Slack. Manufacture of stockings in knitting machines.
762. A. Krupp. Shafts.
765. R. Wilson. Hydraulic machinery and processes.
766. S. Moore. Compressing and cutting tobacco.
782. D. E. Siebe. Refrigerating.
783. R. Kay. Printing calico
786. J. M. Hart and R. Lavender. Generating steam.
793. D. Abercrombie. Power looms.
805. W. Holiday. Press plates.
807. M. Henry. Kilns, ovens, and furnaces. (A communication.)
808. J. H. Brierley. Clasp.
828. W. Clissold. Carding engines.
833. J. Parker. Steam Engines. (A communication.)
836. R. Boby. Hay-making machines.
886. J. Clinton. Flutes.
908. W. Clark. Manufacture of manure. (A communication.)
924. The Rev. G. Scratton. Shades or blinds.
934. W. Clark. Apparatus for manifold writing. (A communication.)
936. W. Clark. Manufacture of carbonic acid. (A communication.)
1017. W. E. Newton. Raising and forcing water and other liquids. (A communication.)
1074. R. A. Brooman. Carriages. (A communication.)
1089. W. Clark. Ornamenting fabrics and other surfaces. (A communication.)
1107. W. E. Newton. Setting artificial teeth. (A communication.)
1152. J. Combe. Hackling flax and other fibrous substances.
1381 C. Lungley. Manœuvring ships and vessels.
1402. J. F. Millward. Breech-loading fire-arms. (A communication.)
1488. G. Davies. Manufacture of ribs for umbrellas.
1757. A. Longbottom. Manufacture of artificial stone.
1857. E. C. Nicholson. Preparation of colouring matters.
1879. J. H. Johnson. Electro voltaic plate work. (A communication.)
1896. C. Beslay. Coating metals by electro chemical agency.
1906. W. Thomas. Running gear of four-wheel carriages.
1908. A. Byrnes. Breech-loading fire-arms.
1990. E. Townsend. Making nails. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed July 18, 1862.

158. A. J. Martin.
159. R. A. Brooman.
160. W. Burgess.
165. F. W. Gerish.
166. E. Pace.
178. A. Ripley.
184. W. Clark.
185. J. Longhurst.
195. J. C. F. Mougin.
235. W. Clark.
246. E. A. Rippingille.
250. W. Clark.
259. W. Walton and F. Walton.
276. T. Cook.
279. W. Clark.
283. D. Joy.
291. C. M. Roullier.
316. M. Henry.
338. M. A. F. Mennons.
650. H. H. Kromschweder.
759. F. Warner.
1003. J. Lawson.
1012. W. Davies.
1015. C. Mather.
1113. J. W. Ford.

Sealed July 22, 1862.

188. T. Morris, R. Wear, and E. H. C. Monckton.
189. C. G. Hall.
194. C. West.
197. D. Edleston and H. Gledhill.
198. E. A. Curley.
200. F. J. L. Lefort.
202. J. Brown and J. Davenport.
207. R. Martindale.
208. C. W. Harrison.
214. H. H. Treppas.
222. S. C. Lister and J. Warburton.
238. B. Foster and J. Moore
242. M. Collier.
244. M. Allen.
245. T. Gontard.
247. J. Firth.
352. A. Lahousse.
353. D. Littlehales.
896. R. Burley.

* Disclaimer and Memorandum of Alteration.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5*s.* must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, AUGUST 1, 1862.

REVOLVING TOWER AND COAST DEFENCES.

What a waking up of public feeling there has been on coast defences since we first aroused attention to the subject! The revolution in naval warfare, resulting from the science of fortification with iron plates, is comprehended by all classes. Two first Lords of the Admiralty vie with each other to announce in the House of Lords those truths which we did our best to inculcate some months ago. The *Times*, moved by this circumstance, is struck with astonishment at the course of the debate in the House of Lords on Friday last, which it designates as "in every respect worthy of the "reputation of that great assembly." The leading journal has been terribly at fault on the armour-plate question, having to steer a middle course between the advocacy of the Armstrong Gun and the Warrior Target. The unhappy reporter who does the naval and military intelligence had a difficult task. If the target resisted the gun, Sir William's fortunes hung in the balance; if the gun prevailed, the Controller of the Navy was driven to despair: hence arose the contradictory statements published in the *Times*, of the results of Target trials, which were extolled as *graphic* by the gallant Secretary of the Admiralty. At last, on that unlucky day when the Minotaur target and the gun both broke down, the truth was suddenly revealed, and the mystification long kept up was swept away.

Armour plating and naval guns, which, combined, are the elements of impregnable ships, have acquired their fixed position of paramount importance, and, warned by the voice of authority, even the *Times* is casting off its reserve, and preparing to admit that there may be better guns than the Armstrong, and better systems of armour-plating than the Warrior's.

On the authority of the Earl of Ellenborough, who spoke out with his usual manly independence, and was corroborated by the Duke of Somerset, the *great fact* we long since published is incontestably announced to the people of England, that "the superiority in "iron-clad ships is now the superiority on sea; "therefore it is essential that we should have "the superiority in iron ships, in order to "recover our superiority on sea, on which our "existence as a first-class power depends."

Impressed with this idea, we lately visited the Naval Arsenal of the International Exhibition, which affords a wide field of instruction on the absorbing subject of the maintenance of our national independence. We contemplated the representatives of the argosies of our forefathers, the fighting ships of the two last generations, and the splendid screw steamers of a few years back with a sigh for their departed glories—as things swallowed up for ever in the vortex of improvement, and we fixed our contemplation on the beautiful model of the Northumberland, and the series of models and drawings, including sections of Captain Cole's cupola ship, as the representatives of the new system of naval warfare, which has entirely superseded the old. We had in our mind the exploits of the Merrimac and the Monitor and the experiments on armour-plated targets at Shoeburyness. Two prominent facts forced themselves on our attention. In a naval combat between the Northumberland or a cupola ship and an invulnerable iron-clad enemy, on the one hand, the terrific effect of horizontal shell firing would speedily cut down everything above the upper deck of the Northumberland, making masts, and spars, and rigging a wreck, with which she would be encumbered, and every man on that deck would be killed or driven below; whilst, on the other hand, the crew of the cupola ship would be unable to remain on the upper deck; and thus, in both cases, the men would be confined within the iron walls of the armour plates. Taking this view, which can hardly be controverted, the advantage of the cupola system is not apparent, but, on the contrary, it offers great disadvantages. The men are cribbed, cabined, and confined; only a limited number to fight the guns could be admitted into the towers, and the rest would be condemned to inaction. The means of boarding an enemy or repelling boarders from a cupola ship without masts or spars, and without ready means of emerging from below on to the upper deck, are extremely restricted, so that at close quarters she would be at a great disadvantage; and it seems that if a number of the enemy had got possession of the deck, they might use mechanical appliances to impede the rotation of the towers, and throw hand grenades or other explosive preparations into the furnace chimney and the openings in the towers, to the great damage of the crew confined below. On board the Northumberland the case would be different. The men could swarm up the hatchway or retire rapidly, either to board an enemy alongside, or to repel a boarding party, or retreat from a sweeping fire. All these movements could be made with alacrity, and the men would have a sense of independent power of action very different from the depressing sensation which the confinement in the bowels of a cupola ship would engender in their minds. If the armour plating of the sides of the Northumberland were shot proof, she would fight an enemy with infinitely greater power and effect than the cupola ship could do. The training of the guns in the latter will depend entirely on machinery, which will be liable to get out of order, and the tower itself may be jammed by the enemy's fire. On reflection, we fear it will be found that the revolving tower system is a mistake, which is founded on the assumed difficulty of making the sides of a ship invulnerable. We have no wish to underrate Captain Cole's ingenious invention, or in the slightest degree to depreciate his merit, but we have to consider which is the best mode of constructing floating defences, and we are of opinion that much still remains to be learnt. We next come to the Monitor arrangement, which appears to differ so little from Captain Cole's plan, of which it is even said to be an imitation, that the objections to one are applicable to the other; and certainly the chances of this class of battery, with only one tower and two guns, are not in its favour, whilst the action of its crew on the upper deck, either to board or resist boarders, would be extremely restricted.

In our last number a description and drawings appeared of another class of revolving tower ship, the invention of Mr. Walker, who is a practical and able engineer. He has himself explained his plan, of which the peculiar feature is that the tower floats on water, and, as he states, will revolve easily; but he does not show how the power to put it in motion is applied. He proposes that his tower should be twenty to thirty feet in diameter, and be armed with five to ten guns, which are to be brought to bear successively, and fired one by one, which he says may be done with great rapidity. He may be right in that particular, but his system precludes broadsides, the mode of firing which, in naval warfare, is the most destructive.

The invulnerable floating battery for efficient harbour defence, as we understand it, has yet to be invented. None of the contrivances of English or foreign inventors, including those which have issued from the prolific brain of American engineers, come up to the ideal of a floating fortress, which should be irresistible when opposed to iron-clad vessels constructed for sea-going purposes. To the production of stupendous engines of naval warfare, which shall carry guns and armour plates far too heavy for the protection or armament of cruisers, the engineering science of the country is directed; and the time, we are persuaded, is not far distant when structures of that description will form our chief maritime coast defence.

On the score of expense, when comparing advanced forts with floating batteries, it is ludicrous to hear the Government organs in Parliament and the press, who are loudly clamouring for a boundless expenditure on inland fortifications, cavilling whether fixed forts or floating batteries will cost most to erect and maintain. The question is, not the price, but which is the right thing? If the floating defence is the right thing, we should like these penny wise and pound foolish economists to inform us why, if our "existence as a first-class power" demand the expenditure of sums varying from 300,000*l.* to 500,000*l.* for the creation of each one of such sea-going men-of-war as the Warrior, Achilles, and Minotaur, the same all-powerful reason does not justify the expenditure of similar sums for the right class of permanent and stationary defences to those vast naval workshops where the iron walls on which our national existence depends are constructed.

About harbour defences there is misapprehension on both sides. As usual in most controversies, each party is too eager to maintain its own argument to accept that of its opponent. The land-defence advocates take no account of sea defences, and the partisans of floating defences depreciate land forts. Both are wrong in confining themselves too exclusively to one view, but there is more sense and more sincerity in the latter. They distinguish between forts for defence on the land side and forts for defence on the sea side—two distinct propositions, which the land-forts advocates ignorantly or purposely confound. As supporters of floating batteries, amongst whom we desire to be foremost, we will reduce the question to its simple expression by two propositions:

1. At the present moment, which object is the most urgent, the defence of our harbours on the side of the land or on the side of the sea?

2. For advanced defences at the entrance of a wide sea channel, as at Spithead, are fixed forts or floating batteries most efficient?

We do not deny the utility of fortifications on the land side, but we say the urgency of providing defences on the sea side is greater: it is, in fact, paramount, and admits of no delay. Clearly, inland defences will be of no avail, except in the contingency of inland attack, which must be preceded by a landing. This contingency is possible, but the enterprise is difficult and unlikely; and, if we maintain the supremacy on the sea, the danger is remote. But now that invulnerable ships are brought into existence, and vertical fire at long range is a certain means of offence, the sudden attack of a naval arsenal is not difficult or improbable;

indeed, it is a risk to which every harbour in the empire within bombarding distance from the sea would be exposed in case of war. To transport and land on our coast, and march inland an army provided with cavalry, artillery, ammunition, and stores, of sufficient force to overcome our army in the field, and make an attack on our harbours on the land side, would be a vast and daring operation. We are not contending that such an enterprise is impossible, but it would be the height of rashness on the part of the invader, and certainly is a remote danger. But when we turn to the other side, the case is different. With a few invulnerable iron-cased ships—some of those American monsters, of which a powerful fleet will be afloat before the end of this year, would answer the purpose—an enemy might make a sudden raid on Portsmouth, and, if we had not got ships equally invulnerable ready to oppose the invaders, the attack could not be resisted. Your inland forts would be of no avail; the enemy would steam into Portsmouth harbour, and, with impunity, destroy your shipping and arsenals, and levy a contribution to save the town from bombardment. This is a likely event, and Ministers will be traitors to the country if they do not guard against it.

Well may Lord Ellenborough express his amazement at the supineness of the Admiralty in the following words:—"The opposition to "the Spithead forts was made on the ground "that iron ships would afford us better protec- "tion, but we have given over the forts and "we have not heard of the iron ships. The "patriotic gentlemen who were anxious to have "iron ships in preference to forts, must feel "disappointed when they find that, though "the latter have been given up in the case of "Spithead, there is no additional grant asked, "for what they propose as a substitute."

Fortunately, the reply of the Duke of Somerset offers some consolation to the country. He announced that he had not spent all the money "voted last year for iron-clad ships, "and he therefore did not think it necessary "to ask Parliament for more money for that "purpose." We may, therefore, hope, now that the attention of Government is awakened to the urgent necessity of protecting our harbours on the side of the sea, and fixed forts are condemned, proper encouragement will be given to proposals for the construction of powerful and efficient floating batteries.

THE GOLD COINAGE OF AUSTRALIA.

It is with no small amount of gratification that we record the fact of a select committee of the House of Commons having last week reported in favour of legalising, and, indeed, of imperialising, the gold coinage of Australia. The utter absurdity of the arrangement which permitted the establishment of a Branch Mint in Sydney, and yet limited the circulation of coin emanating from its presses to the colonies of Australia, has repeatedly been exposed in our columns; and it is a legitimate source of pleasure, therefore, to find our views now completely endorsed by Parliamentary authority. The report of the committee is published, and it is desirable, perhaps, to point out some of the reasons which have induced its members to come to the conclusions at which we had long since arrived.

The first witness examined was Mr. Thomas Graham, F.R.S., Master of Her Majesty's Mint, and his evidence, which is at once clear and convincing, went to show the existing regulations in reference to the Sydney Mint, and the evils arising from them. Without following Mr. Graham through the minute details into which he felt it necessary to enter, it may not be irrelevant to give an abstract of his testimony. From his statement, then, it appears that, in consonance with an Order in Council of the year previous, the Branch Mint of Sydney went into operation in May, 1855. The officers of the establishment are appointed by the Lords Commissioners of the Treasury, and sovereigns and half-sovereigns are the only coins stamped thereat. The Sydney Mint does not entail any charges on the imperial funds, the entire cost of its original establishment, and the annual salaries and contingencies of the department, being defrayed by the Colonial Treasury of New South Wales. To meet this expenditure, a charge is made on all gold brought to the Mint, whether for coinage or for melting, assaying, or running into bars, the same amount being levied for either process. The charge for these operations, according to the last published regulations, is equal to three-quarter per cent. upon the parcels of gold introduced. The mode of insuring payment from fortunate diggers, and others who avail themselves of the assistance of the Mint, is rather remarkable, and betokens something like "sharp practice" on the part of the officials. For instance, in the case of a person leaving raw gold for the purpose of coinage of the value of 1,000 sovereigns, he would receive only 990 in return, the ten sovereigns being retained as Mintage charges. There is no doubt that this is a very safe proceeding on the part of the Mint, but it certainly does not quite square with the "last published regula- "tions," which, as we have just seen, enact that the cost of Minting shall be three-quarter per cent. If ten pounds in a thousand be not just one per cent., we are rather at fault in our arithmetic. The Master of the Mint bears witness, however, to the fidelity with which the enactments of the order in Council, in respect to the standards of weight and fineness of the coins issued from the Sydney Mint, have been carried out. Mechanically speaking, he does not consider, however, that the coinage is so well executed as that of the British Mint. This he attributes, and no doubt justly attributes, to the fact that the coining presses of Sydney are on the *lever*, instead of the *screw* principle. Those who have had any practical acquaintanceship with the manufacture of coin, will at once admit, we should think, that the sharp blow administered by the screw press to a disc of metal, is more likely to bring out the impression from the die with the proper degree of sharpness than the gentle squeeze of a lever press.

Another advantage which the screw press possesses is, that its impact upon the metal to be converted into coin being sharp and sudden, like the blow of a hammer, it gives the piece of money a greater amount of density than it would otherwise acquire, and thus fits it better for the wear and tear of circulation. It is as well to note this in passing, because it may become a question with the colonists whether, now that their coins stand a chance of finding their way into the channels of universal circulation, it will not be desirable to endue those coins with the elements of long life.

Returning to the commercial phase of the question, we find that the witnesses examined by the committee almost all admit the inconvenience of having two gold coins, of equal fineness and weight, consequently of the same intrinsic value, and bearing the same denomination, not enjoying an equal privilege of circulation within the realm. This inconvenience is particularly experienced in the large trade carried on between Australia and our possessions of Ceylon and the Mauritius. In commerce, too, with the sister colonies named, and also with India, Manilla, Java, and other countries into which Australian gold coin largely enters, there is no doubt that the imperial sovereign is more highly valued than the sovereign at present issued from the Sydney Mint. This fact, and the complications and annoyances to which it inevitably gives rise, are considerations surely well worthy the attention of the Home Government.

In reference to this unhappy state of things, the report of the committee is singularly plain-spoken; and it almost reiterates, indeed, a remark made in the "Mechanics' Ma- "gazine" of June last on the same subject, to the effect that, "as Australia is one of the "possessions of the Crown, and the two "countries (i. e. England and Australia) "having the same currency, it may be fairly "questioned whether there ought to be any "distinction between the two coinages." The committee further assert that, by perpetuating the present arrangement, we should omit an opportunity of promoting uniformity in our gold currency, inasmuch as that arrangement invests the sovereign issued at the imperial Mint with two qualities—one being, that it must be taken by Australians as current money for all they have to sell; and the other, that until it has undergone a fresh assay, and obtained a new stamp, it is not to be available as current money in the United Kingdom.

It is for reasons such as these, and many others which we have in times past enumerated, that the Colonial Legislatures have expressed a strong desire to see the Australian sovereign relieved from the legal inferiority which now attaches to it.

The question may, as the committee suggest, be undoubtedly asked whether, if the privilege of circulation within the United Kingdom were conferred on the Sydney sovereign, Australian gold would cease to be transmitted to this country in the form of bullion, and that all the gold found in Australia would be taken to the Branch Mint of Sydney for the purpose of coinage? It may, however, be fairly assumed that the bulk of the Australian gold required in the ordinary trade with the United Kingdom would still come here in the more merchantable form of bars, as being the cheaper medium of exchange. It is not at all likely that a banker or merchant would carry gold to the Branch Mint at Sydney, and bear the expense and delay of having it made into coin at that limited establishment, the present rates of seignorage being maintained, when, on its importation to this country, the process would be more readily and cheaply effected here.

On the other hand, so long as the present restraint on the home circulation continues, the great majority of Sydney sovereigns which reach this country are forced into the melter's crucible to become again fractions of ingots, because they possess no more worth here in the form of coin than they possessed in Australia in the form of bars. The chief objections raised by the few opponents of the imperialisation of the Australian gold coinage who appeared before Alderman Salomons' committee, were "the fear of a systematic "introduction of light Australian coin into "our home circulation, and the inconvenience "likely to result from the existence of a "plurality of Mints."

The committee dispose of these puerile and theoretical exceptions in a summary but satis-

factory manner. They assert that, as to light gold being collected in Australia and sent here, the answer is obvious. Light gold in large quantities can only arise from abrasion fraudulently effected, or from fair wear and tear. The profit that might be made from such a trade must be purely visionary, for it would never pay the interest of the money necessary for carrying it on in a country where the rate of interest is so high as in Australia. It will be difficult for anyone to overturn an argument so well based as this; and we do not suppose that even Mr. Hankey will attempt the Herculean task. Supposing for a moment the possibility of Australian light gold being systematically introduced here, the loss would fall, as it now does, on the possessor of the coin. How, indeed, would it be got into circulation? Neither the Bank of England nor bankers generally would take it; nor would dealers receive it, unless in the usual way, through their scales. Looking at this notion from any rational point of view, it is, as the committee mildly say, "visionary."

There remains the other suggested contingency, a plurality of Mints. For our own parts, we can see no real objection to a plurality of Mints; and certainly at Melbourne there should be established another branch of the Royal Mint. We have three Mints in India, and we have to learn that any inconvenience has arisen from their existence. On the contrary, we think it could be easily shown that they are of inestimable good to the Indian community. Even in England, in times past, there existed a plurality of Mints.

Before the vigorous assaults of the members of the select committee, these shadowy phantoms fortunately disappeared; and, in coming to the general conclusions, which we append, the members of that committee have entitled themselves to the thanks of the British commercial public, and to the gratitude of the colonists of Australia.

It remains for the Ministry to amend the order in Council of 1854 on the bases here laid down:—"1. That gold coin be issued "from the Branch Mint at Sydney having currency in all parts of the British dominions "where gold coin minted in London is current. "2. That the coin struck at the Sydney Mint "should have, as nearly as possible, the same "alloy and the same quality of execution and "durability as that struck at the Royal Mint "in London. 3. That the coin should also "have a Mint mark sufficient to indicate, at "least to bankers and others, the Mint whence "it issued. 4. That an adequate Mint charge "or seignorage should continue to be levied, "and that the imperial Government should "stipulate for its being kept at such an "amount, as to prevent any undue inducement "to the importation into the United Kingdom "of gold in coin rather than in bars. 5. That "arrangements should be made for with"drawing from circulation, as speedily as "possible, the existing Sydney gold coinage. "6. That the charge for the Branch Mint "should be provided for by permanent appro"priation by the Legislature of New South "Wales, rather than by an annual vote."

We take the liberty of adding a 7th clause, and it is a practical one, namely, "That the "mechanical arrangements of the Sydney Mint "shall be remodelled, screw presses being "substituted for lever presses."

Mr. Blanchard Jerrold writes in the *Star*, thanking theatrical managers, manufacturers, and others, for their good offices in behalf of foreign workmen visiting the Exhibition, and stating that four banquets are being organised, to be given to foreign workmen in the Exhibition, at which British workmen are invited to be hosts.

THE CONSTITUTION OF THE ADMIRALTY.

The conduct of the Admiralty in adopting improvements does little credit to its foresight, independence, or patriotic sentiment.

It originates nothing; it contents itself with watching our allies across the Channel, moves after they have moved, but is always behind; copies their inventions, and takes no serious measures to guard against a new form of danger until it is suddenly awakened to alarm by learning from its diplomatic spies that some new class of ship, or some new armament, with augmented powers of offence and destruction, has been exclusively introduced in the naval service of our neighbours; then sudden alarm seizes the Lords Commissioners, who discover that the country is in danger, that the activity in the French dockyards portends invasion of England, and forthwith all is energy and haste in their councils. But even in these times of excitement, which are of periodical recurrence, the Admiralty makes no appeal to the immense resources and creative power of our private yards without the sanction of the Controller of the Navy, who governs the maritime destiny of the nation. The Lords are dependent on this powerful but inefficient official. The trammels of routine cannot be shaken off. "Perish the colonies, rather than abandon a "principle!" cried the enthusiastic republican; "Perish the nation, rather than cast off the "tutelage of the Controller!" is the undying sentiment of my Lords. The extent to which this sentiment is acted upon would be ludicrous if it were not so fatal to the best interests of the country. Under the tall portico in Whitehall, red tapeism is predominant. Does a question arise which in any way relates to construction, straight it is referred to the Controller, who refers the matter to his subordinates, for he will not venture to form an opinion of his own, and their fiat is reported to the Board, and determines the final decision. Then it comes to pass that they who know the ways of the Admiralty, and have the *entrée* to the official presence, attain their object; but the uninitiated, to whom the avenues to that distinction are tabooed, have not a chance of success for the most legitimate and advantageous proposals. The report goes forth that these proposals are not beneficial to the service, or that they offer difficulties of execution, and forthwith a stereotyped letter is addressed to the applicants, informing them "that their "Lordships are not prepared to adopt the pro"position." This euphemism of cold refusal is sometimes varied with "at *present*," leading the deluded individual to the fallacious hope that his proposal is not finally rejected, and he lingers at the Admiralty threshold in all the misery of hope deferred. A gallant Captain, it has been lately stated, danced attendance on the arbiters of naval construction seven years, and when at last, in his despair, he wrote to the *Times*, and appealed to the House of Commons, he was upbraided as an ingrate, who listened to the counsels of injudicious friends, and affectionately told to rely upon the Admiralty.

It was the Secretary who gave this kind advice. But let us see how he acquired his post: was it by relying on the Admiralty? If we remember rightly, it was by a totally opposite course that he succeeded in grasping the emoluments of office, which offered great attractions to his mind. By diligent research, and the help of a friend who was not *green* in the arcana of naval construction, he produced an analysis of Admiralty accounts so profound that it was incomprehensible; but this constituted its chief merit, and he proved—at least, he said he proved — that there was a deficiency of three millions in the Controller's accounts. The sensation created by this bold assertion at the time is not forgotten. It answered its purpose. The self-constituted auditor of the Controller's accounts obtained the appointment he coveted. Why should he not? Had he not exposed a great delinquency, and deserved his reward? But what followed? No sooner was the new Secretary in office, than it oozed out that there was some oversight in his calculations: he had to retract his charges, and admit he had discovered a mare's nest. Would it not be thought that on this exposure of ignorance, or something worse, this pretender would be ousted from office? But no such thing; he was appointed by his colleagues as a congenial spirit, and quite lately the Premier told the House of Commons he congratulated himself on having so useful and clever a secretary.

If we attempt to analyse the constitution of the Admiralty, we find it composed of a singular triumvirate, namely, the Lords, the Secretary, and the Controller, whose powers and attributes are so strangely blended and so oddly dependent on, or independent of, each other, that the public has not the most remote conception, and it would puzzle themselves to define, where the jurisdiction of each begins and ends. Are they coeval and coexistent, and do they possess a joint and common power, a veritable "*tria juncta in uno*," or does each exercise a separate action, for which he is responsible? These are some of the mysteries we have referred to.

Dismissing metaphor, we opine that in this anomalous composition is to be traced the notorious inefficiency of our naval administration. For executive incapacity it is not to be equalled by any department of the most despotic and corrupt Government, and there will be no improvement until the Admiralty is reorganised. Our ancestors were sensible of the defective character of the institution, and, as a corrective, conceived the idea of a Lord High Admiral; but the appointment of this exalted officer, which was the embodiment of an occasional Minister of Marine with dictatorial powers, was made only in cases of emergency. The existence of such power vested in the Crown proves a wholesome mistrust of the ordinary administration of the navy. Aristocratic jealousy is, no doubt, the reason why the office has fallen into desuetude, and we cannot say we are in favour of a kind of ministerial appointment which depends upon the "*bon plaisir*" of the sovereign. At the same time, we see in the existence of this right the germ of a better order of things than "Lords Commissioners," and, without intending any discourtesy to my Lords, we shall rejoice when their office is abolished, and a responsible Naval Minister appointed in their place. The noblemen and gentlemen who rejoice in the title of "my Lords" are all honourable men, and no doubt patriotic, but it requires little wisdom to understand that a power so divided, so irresponsible, and so servilely dependent on its own executive department must be, as it is, feeble, vacillating, and effete.

Only fancy a commander-in-chief being under the orders of his own commissariat; but that is precisely the position of the Lords in respect of the Controller. No doubt all the officials of the Admiralty intend to do their duty, but irresponsibility begets indifference and represses talent. Each hopes to escape censure for any mishap by referring everything to some one else; and, under such

enervating influences, each thinks more of the honours or the emoluments of office than the performance of a public duty.

Under this strange constitution, the Controller, although nominally under the order of the Board, holds the sovereign power, because, in a manner, he guides if he does not hold the conscience of the Lords, who are so conscious of this fact, and feel themselves so helpless without his guidance, that it would be a bold Lord who, on a question of construction, should travel out of the tradition of routine.

The Secretary of the Admiralty—it is hardly possible to define his position. In the House of Commons he is almost a Minister, and takes a tone and attitude which lead foreigners to regard him as the "Minister of Marine." Many Englishmen, we are persuaded, ascribe to him the same high attribute, and the puissant Lords, his masters, are often glad to shelter themselves under his wing. To give a familiar idea of the composition of this department, no comparison is more to the purpose than the management of a joint-stock company. The Lords are the Board of Directors; the Secretary is the clever official with the same title who leads the Board, and the Controller is the shrewd manager who conducts the works, who has a good understanding with Mr. Secretary, and, by making himself agreeable to the chairman, usually manages everything and everybody. But this is not the organisation for a great public department of a great nation, and we hope soon to see the day when it is superseded by a Navy Minister, with power and responsibility duly combined.

An event of importance to the country, which has occurred within a few days, is a proof of the lamentable maladministration under the present system. Shortly after the trial of the Minotaur target at Shoeburyness, the failure of which was fully reported in our columns, the Admiralty, convinced by the result that the mode of armour-plating adopted for the frigates of that class was less effective than that of the Warrior, determined to make some change, so as to insure more efficient protection to those vessels. The constructive talent of the Controller, who was the designer of the plan which broke down at the trial, was again called into requisition, and, under his orders, two plans of modification were devised. These were submitted to the contractors for the Minotaur vessels, who were requested to send in estimates of the expense which the change would entail. Contractors never fail to profit by alterations in a specification, and it turned out that one of the contractors demanded for those proposed some 6,000*l*. or 8,000*l*. in addition to the contract price. The Admiralty, dissatisfied at this demand, declined further negotiation with the firm in question, and ordered the frigate to be completed, according to the original design, with the armour-plating *unaltered*.

Here we have a sad picture. First, a system of armour-plating, rashly adopted *without previous trial*, is ordered for three large frigates. Then, admonished by the defects of the Warrior system, which also had been adopted without previous trial, the Admiralty bethink themselves of experimenting on a Minotaur target, when, to their dismay, they discover that with plates $5\frac{1}{2}$ inches in thickness, when those of the Warrior are only $4\frac{1}{2}$ inches, the supposed improved plan is worse than its predecessor. Forthwith two new plans are contrived, and these, again, with no guarantee for their efficacy but the opinion of the Controller, who was twice wrong before, are proposed for adoption *without trial!* One is amazed and bewildered at such inconsistency. But the climax is to come. Because the Controller and the contractor cannot agree about price, the avowedly bad system—proved to be bad by actual trial—is to be carried into effect, and a magnificent frigate, superior to the Warrior in dimensions, armament, and power, is to be left to the chances of defeat and destruction in the first battle with a hostile ship more efficiently armour-plated than herself.

We cannot repress our indignation at this act, and we trust, if there be yet time before the close of the session, a question will be put to the first Lord of the Admiralty, so that the precise truth of this astounding dereliction of duty may be known. A decision thus come to with unpardonable levity and haste, whereby a splendid war ship, which will cost nearly half a million, and the honour and security of the nation are jeopardised, is an act which certainly would justify the impeachment of the ministers who should deliberately sanction it. We pause till next week for an explanation, and we shall rejoice if it can be shown we are mistaken.

CAPTAIN GRANT AND THE WAR DEPARTMENT.

CAPTAIN GRANT and his dealings with the War Department will one day form a most interesting portion of the biography (should it ever be written) of those inventors who have made proposals to the Government Departments, and been more or less engaged in carrying their plans into execution. With a persistency of purpose which does much credit to General Lindsay, he has succeeded, first, in obtaining copies of all the correspondence that has taken place this year between the Under-Secretary of War and Captain Grant, respecting his claims for the services he has rendered in improving the system of cooking in the army; secondly, of all official reports that have been received at the War Office upon the system of cookery established by Captain Grant at the various camps, and upon his ambulatory cooking apparatus; thirdly, in getting what we may call a practical majority in the House of Commons in favour of Captain Grant being remunerated for his trouble; and lastly, in obtaining the consent of Sir G. C. Lewis to the appointment of a committee of enquiry into Captain Grant's claims. Thus the battle has been fairly fought and won; for, although committees of enquiry are not infallible, yet there is no reason to doubt that some justice will be done upon the termination of the committee's labours. No man should be subjected to the necessity of making such innumerable applications as has been requisite in Captain Grant's case, not only before obtaining substantial reward, but even before obtaining permission to place the facts before an impartial tribunal. We have no desire to offer any opinion upon the exact amount fairly due to the Captain for the time and trouble he has taken to improve the cooking for the army, although to determine this there is abundant matter now before the public, but we are desirous of pointing out the very important fact, that Captain Grant's claims cannot equitably be made to depend upon the question of his arrangement of cooking apparatus being the best or most economical now known or in use.

It must be recollected that it is now upwards of *seven years* since Captain Grant first drew attention to the imperfections of the ordinary arrangements in use for cooking soldiers' food, whether in barracks, or on march, or in camp. Some six years since we fully examined his plans in use at Woolwich, and, although we believed at that time that the whole of the arrangements were not so perfect as they would ultimately be made, no one could possibly doubt that an immense step had been taken towards a permanent improvement in cooking for the army. In the ordinary kitchen we visited at Woolwich, ranges of seven coppers were heated by seven distinct fires, which, of course, had to be separately lighted and attended to, there being no arrangement whatever for baking any part of the food. Nothing could possibly be more primitive than the whole system adopted, not even excepting the cooking arrangements of a party of common gipsies. An immense quantity of fuel was necessarily wasted, owing to the multitude of fire grates, and, as we have stated, no baking could be done at all. We believe a few soldiers, in turns, had permission to take their dinners to a baker's oven; but from the great distance the food had to be brought, as well as the expense of getting it baked, few availed themselves of the privilege, the result being that the men lived wholly upon boiled food, or nearly so.

In Captain Grant's arrangement, *one fire* did the whole work, boiling as many kettles, and at the last heating an oven, in which any fair proportion of the men's rations could be well and easily baked. The utility of fitting up this improved apparatus was, however, by no means confined to the actual economy and convenience then experienced by its use. It showed the miserable system upon which the soldiers were before compelled to cook their food, and naturally *set people thinking* as to what could be further done. In a word, Captain Grant, against much opposition and discouragement, *originated the movement* for improving army cooking; and if all the barrack authorities put together were now to give evidence that subsequent plans of cooking were preferable to Captain Grant's, this could not alter his claim to compensation, inasmuch as at the time he introduced his system, however imperfect in some of its details it might have been, it cannot be denied that it was very greatly superior to other methods, or rather to the only method then in use. We must recollect, however, that no such general condemnation of Captain Grant's plans has at any time been made. Indeed, we find, throughout the reports and correspondence on this subject, many very weighty reasons for preferring his apparatus to that used by others. By one report, dated February 1857, we find, from careful experiments in cooking for 424 men, the cost of cooking with Captain Grant's kitchen was 2*s*. $6\frac{3}{4}$*d*., whereas that of cooking in kitchens of the barrack pattern was 3*s*. $3\frac{3}{4}$*d*., and that of the gas kitchen 5*s*. 10*d*. Moreover, that the men much preferred the meat baked in the first apparatus referred to.

Captain Grant's claims must be judged by a comparison of his apparatus (perhaps in its most *improved* form, inasmuch as the War Department have so long resisted those claims) with that in use at the time he introduced his apparatus into the service. It has, doubtless, been an easy matter for others to take up the subject since Captain Grant first applied himself to it, and, having before them the numerous experiments he has made, to devise methods of arranging plans which may have some advantages. We by no means say this has been done — there is no proof of it having been done; but if it has, or should it hereafter be accomplished, it will be mainly due to Captain Grant's exertions. To him, then, let recompense be first made.

MANUFACTURE OF DAMASCUS SWORDS.

IN olden times the city of Damascus, in Syria, was renowned for its cutlery, and particularly for the manufacture of sword blades. The fame of these swords extended throughout Asia and most of Europe. They were so elastic that they could be bent like hoops without breaking, while at the same time their cutting edge was as keen as that of a razor. Damascus blades possess a wavy surface of regular bright and dark lines, and the mode of manufacturing them was kept a profound secret by the armourers of that city. Rees, in his Cyclopædia, states that they were made of a peculiar kind of steel, and it was the character of the metal, not the mode of making them, which gave them such superiority. The same idea is conveyed in the interesting article on the subject in the "New American Cyclopædia." From information which we have received on the subject—and which we shall hereafter cite—such statements do not appear to be reliable. Rees says of Damascus swords:—"About the beginning of the fourteenth century, Timeur Leng, on his conquest of Syria, conveyed all the celebrated manufacturers of steel from Damascus to Persia. Since that period its works in steel are little memorable. They were formerly of the highest reputation in Europe and the East. The famous sabres appear to have been constructed by a method, now lost, of alternate layers, about two or three times thick, of iron and steel. They never broke, though bent in the most violent manner, and they retained the utmost power of edge, so that common iron, and even steel, would divide under their force."

The method of manufacturing Damascus blades was undoubtedly lost for centuries, but the "New American Cyclopædia" states that the Russian General, Anossoff, rediscovered the process of producing Damascus steel, by smelting 11 lbs. of charcoal iron in a crucible with $\frac{1}{12}$th of graphite, $\frac{1}{32}$nd part of iron scales, and about $\frac{1}{24}$th of a fusible flux such as dolomite. These substances are submitted to intense heat, in a blast furnace, for about five hours, when the scoria is scummed off, and the molten ingot of steel thus formed is drawn under the hammer, and submitted to several heatings and hammerings. Of steel thus made, it is asserted that General Anossoff made several blades like those of Damascus, having the same dark and light wavy lines, which were produced after the blade was formed by pouring dilute sulphuric acid over it. General Anossoff died in 1851, and it is stated that his successors have not been able to produce such like swords. We do not wonder at this, for assuredly swords of the Damascus appearance, with wavy lines, cannot be made from bars of pure steel. The waving lines on such swords nearly resemble the minute and graceful shadings of the fine watered silk of which ladies' dresses are made, and they are due to the method of fabricating the blade, and also to the combined metals of which it is composed. Blades resembling the old Damascus cimeters are not uncommon in this city, and they equal them in temper and elasticity. We are indebted to Mr. Herman Vasseur, No. 9 Maiden Lane, in this city, sword mounter and scabbard manufacturer, for a description of these blades. They are made at Solingen, in Germany, the only establishment of the kind in the world. A faggot is first formed of alternate fine bars, or wires, of iron and steel. Such a faggot is then drawn out, doubled and twisted several times, and formed into a ribbon. Two of such forged ribbons of iron and steel are then welded together, enclosing a thin blade between them of the best cutting English steel, and thus a Solingen Damascus blade is formed. The interior thin blade of English steel gives the sword a desirable and perfect cutting edge, and the combined twisted iron and steel outside layers impart to it peculiar toughness as well as the beautiful wavy surface for which it is also much prized. When ground and polished, no wavy lines are recognised, but by dipping the blade for a short period into dilute sulphuric acid, a portion of the iron on the surface is dissolved, while the carbon of the fine steel bars is unaffected, and appears in dark wavy lines contradistinguished from the white wavy surfaces of the iron bars. These blades are imported plain, and mounted in this city. Mr. Vasseur has lately mounted some of them in a splendid manner, to order, as presentation swords for several officers of our army and navy. The scabbards are made wholly of silver, and highly ornamented, while the hilts are tastefully mounted, with appropriate designs, partly cast and partly engraved. A silver scabbard is made by hammering rolled plate silver upon an iron mandrel of the proper form, and thus the plain sheath is produced. The ornaments, consisting of neat designs in silver, are cast from patterns, then trimmed and soldered to the sheath. A considerable portion of these silver scabbards are also gilt. They are certainly splendid specimens of sword mounting.

The inlaying of iron and steel with gold and silver is called Damaskeening, because this art was carried on upon a great scale when Damascus was the armoury of Syria. It is executed by cutting burr grooves with a cold chisel, in the steel before it is hardened, and then hammering gold or silver wire in these grooves. This art is of great antiquity. We have read and heard it frequently stated that the superiority of Damascus swords was due to the mode of tempering them. This consisted in heating the hardened blade to a blue colour, and handing it to a rider sitting on horseback, who instantly started off at a gallop, waving the blade against the cold north wind, which was required to be blowing at the time, or the operation could not be performed. We put no credence in such stories, because it is scarcely possible to temper a piece of very thin steel by waving it in the atmosphere, at a high velocity, during the coldest days in winter. The beauty and superiority of the Solingen blades must be credited chiefly to the skill of the artisans who fabricate them.—*Scientific American.*

THE INTERNATIONAL EXHIBITION.

CLASS I.

(Concluded from page 53.)

THERE are some beautiful and interesting objects in Class I. of Norway, especially the native and other silver ores from Kongsberg. Aall and Sons exhibit magnetic iron ores and products obtained therefrom at the works at Næs, near Arendal. Among these are specimens of pig-iron, bar-iron, and steel, which, doubtless, are of good quality.

Belgium displays an extensive and well-arranged series of her mineral products; and among them are very numerous and characteristic specimens of brown hæmatites, and these, if we mistake not, are the chief source of her iron. It would appear from the labels attached to these specimens, that the ore contains on an average about 34 per cent. of iron. The Belgian coalfield, like that of Northumberland, is deficient in workable measures of clay iron ore. There are some fine specimens of a somewhat peculiar variety of red hæmatite, which is stated to occur at or below the base of the carboniferous limestone at Vezin, near Liége, No. 28. Ore extremely similar to this in all respects has recently been discovered in South Wales, in a similar geological position. We regret that we cannot congratulate Belgium on the position which she occupies in the Exhibition with regard to her iron industry as illustrated in Class I.

France has interesting objects in Class I., which we shall notice hereafter, but there is little to indicate her possession of extensive iron-making resources. Brown hæmatite occurs extensively in the oolite of France, and is the chief ore smelted. Beautiful brown hæmatite and some spathose ore are found in the Pyrenees, and have furnished supplies during several centuries to the Catalan forges of that district. We consider that the iron manufacture of France is very imperfectly represented at the Exhibition, many of the great works not having contributed a specimen. We are at a loss to divine the reason of this, unless the ironmasters across the Channel feared competition with the world, or, under the protection of existing tariffs, felt no stimulus to exertion.

Spain is wretchedly represented in Class I., and this is greatly to be regretted, as it is well known that she possesses great mineral wealth, which, of late years, has been rapidly developed. It is obvious that the persons intrusted with the arrangement of this class knew absolutely nothing about their business; and we have been informed that the jurors have made several ineffectual attempts to extract information from them. Their courtesy was all that could be desired, though their ignorance was profound. One reason which they assigned for the poverty of the collection was, that they were not allowed to accumulate too many heavy articles on the gallery where it is placed; whereupon a French *savant*, who happened to be present, exclaimed with characteristic *naïveté*, "Mais pourquoi avez-vous mis vos étoffes en bas et vos pierres en haut?" Another and much better reason is, that more than 100 cases of minerals are lying in the docks for want of sufficient space in the Exhibition. This is to be deplored, as there can be little doubt that both Spain and Great Britain would be mutually benefited by a display of their contents. Is it yet too late? We have heard it stated that the gentleman charged with the direction of this class is a Colonel of Artillery, and related to His Excellency the Spanish Ambassador; in which case all that can be said is that the mineral kingdom of Spain has a far less efficient representative at the International Exhibition than the political kingdom at the Court of St. James.

Portugal makes a respectable appearance in Class I., but there is really nothing relating to iron. It is presided over by a well-informed Portuguese mining engineer, M. Cabral, who is anxious to do his best to develop the mineral resources of his country. A useful catalogue in French of the specimens exhibited in this class has been published.

The kingdom of Italy has acquitted herself with much credit in Class I. The collection is extensive, and in many respects highly interesting, especially in reference to ores of copper and lead. It contains beautiful and characteristic examples of specular ore from Tuscany, of brown ore and spathose carbonate from various districts. The vicinity of Bergamo is classic ground in the history of iron-smelting. There is an excellent descriptive catalogue of this class in Italian.

Canada is most worthily represented in Class I., thanks to the director of the Canadian Geological Survey, Sir William Logan. Justice compels us to deviate from the course which we have hitherto pursued, and bestow more than a passing notice on this indefatigable geologist. Unaided, he commenced, in 1831, a geological survey of part of the great South Welsh coalfield extending from Cwm Avon to Carmarthen Bay, and completed it in seven years, at no small pecuniary sacrifice. Such was the estimate of the accuracy and value of this survey by the late director of the Geological Survey of Great Britain, Sir Henry De La Beche, that, with Sir William's consent, it was adopted as part of the national work. In 1842 Sir William went to Canada, where he has ever since resided, devoting his life, with a singleness and earnestness of purpose truly remarkable, to the exploration of the structure and the mineral resources of that vast territory. Not having the advantage of an accurate map of the country, such as has been supplied to our home geologists by the Ordnance Survey, he has been obliged to make a topographical survey *pari passu* with a geological one. Few persons can imagine the arduous nature of this work. Our indomitable geologist is often compelled to penetrate the trackless primeval forest, to force his way across the tangled cedar swamp, and brave the dangers of Canadian Rapids in a frail canoe; and to these difficulties we may add that his path is disputed at every step by the most relentless and invincible foes with which man in these regions has to contend—countless hosts of mosquitoes and black flies. Very different is the comparatively light and gentlemanlike occupation of our home geologists, who have no such hardships to encounter, and, after the pleasant ramble of the day, never fail to enjoy the luxury of an English cottage. Sir William Logan has neither sought wealth nor

honours, but has quietly and modestly pursued the one great object of his life with a devotion as rare as it is praiseworthy. Let it not be supposed that this eulogium is prompted by any feeling of personal regard: it is a just tribute, and no more, to a man who has striven, during many years, to develop the vast mineral resources of Canada, not with a view to his own advantage, but from pure love of his work. We are glad to know that the Canadian Government fully appreciate the value of the labours of this self-denying and faithful public servant. The Canadian territory comprises about 300,000 square miles, and about 100,000 have already been surveyed by Sir William and his small staff of assistants.

Enormous deposits of magnetic iron ore—which, when pure, is the richest of all the ores of iron—have been discovered by Sir William Logan in the Laurentian rocks, which present no traces of organic remains, and are the oldest sedimentary series in the world. The ore occurs interstratified with the rocks containing it. The accumulation of this ore in some localities is so great as to appear incredible. Thus, one bed is not less than 500 feet thick! On the Rideau Canal there is another bed 200 feet thick, which is now worked at Newborough, and from which the ore is conveyed to Kingston on Lake Ontario. From this place it is put on board vessels at a cost of \$2¼ per ton and taken to Cleveland, on Lake Erie, Ohio, whence it is sent to Pittsburgh, Pennsylvania, to be smelted. The best quality of ore is met with in a bed 25 feet thick in the township of Madoc. Fine samples of all these ores are exhibited. Canada also possesses extensive tracts of bog-iron ore on the north side of the St. Lawrence, and this is the only ore which is at present smelted in the country, charcoal being the fuel. The smelting is conducted at the Radnor Works, which include a forge for the manufacture of iron. At these works a large number of railway wheels are made of cast-iron derived exclusively from bog-iron ore. Cast-iron from ordinary bog-iron ore is about the last kind of metal many founders would dream of employing for such a purpose; and yet in the Canadian department of Class I. is exhibited a pair of railway wheels which have travelled, without showing much evidence of wear, not less than 150,000 miles, or about six times round the earth. And it should be remembered that in Canada there are great alternations of temperature, the heat of summer being intense, and the cold of winter extremely bitter. These bog ores must be exceptionally free from phosphoric acid; for otherwise they would yield a tender, and not a strong iron like that of which the wheels above-mentioned are stated to consist. Massive and characteristic specimens of magnetic ores are exhibited, as well as fine specimens of bog-iron ore and red hæmatite. Large lumps of red ore from the Silurian rocks are also shown, but they are of inferior value from containing a large amount of earthy matter, and frequently less than 50 per cent. of metallic iron. There is a descriptive catalogue, by Sir W. Logan, of the economic minerals in the Canadian department, which is replete with valuable information, scientific as well as commercial, and we can recommend it with confidence to all who are interested in the subject.

Nova Scotia makes a good display of her mineral products, and among these are large lumps of brown hæmatite and specular iron ore, which supply the furnaces of the Acadian Ironworks. Pig and bar iron from these works are also exhibited. In the useful descriptive catalogue of the articles sent by this province it is stated that 1,200 tons of iron are annually made, of the value of 16*l*. per ton. The present Acadian Company, we have reason to know, differs much in proprietary and management from the old company of the same name, which a few years ago, it may be remembered, somewhat ostentatiously obtruded its iron upon the British public as of surpassing excellence. When complaints were heard of the bad quality of our cast-iron ordnance during the Crimean war, it was loudly proclaimed that Acadian iron was the thing wanted to insure perfection in future, and considerable quantities of it were supplied to the Arsenal at Woolwich. Some of it was found to be good, and some wretchedly bad, as anyone may learn by consulting the valuable blue-book on "Cast Iron Experiments" published in 1858. In four out of eight analyses of Acadian pig-iron given by Mr. Abel, chemist at the Arsenal, in this Blue-book, the phosphorus ranges from 1·3 to 2·1 per cent., and in one sample of grey pig the silicon amounted to 4·23 per cent. We trust the present company may not unjustly suffer from the mistakes of their predecessors; but the old proverb, "Give a dog a bad name," &c., may apply to an iron company as well as our domestic friend. It is declared that some bad varieties of ore formerly used have been discarded, and of these specimens were pointed out to us in the Nova Scotia department with no small degree of contempt. Why, then, were they exhibited?

The Australian department is specially distinguished for its magnificent copper ores, to which we shall revert on a future occasion; and we noticed a large and fine specimen of spathose carbonate of iron. This may possibly indicate the existence of deposits of ore which may hereafter prove more valuable than stores of gold. But we are reminded of the gilded pyramid facing the entrance at the eastern dome. We are informed that this is an exact measure of the bulk of all the gold hitherto extracted in the colony; but we confess that it fails to impress us with the idea of magnitude, and though the conception is ingenious, its realization in the form of a pyramid is a failure. This object is, we presume, called a trophy, and the following well-known lines might with propriety be inscribed upon it, with a view to the edification of all, including even Her Majesty's Royal Commissioners:—

> "Gold! gold! gold! gold!
> Bright and yellow, hard and cold,
> Molten, graven, hammer'd, and roll'd;
> Heavy to get, and light to hold."

There is an interesting series illustrative of Class I. in the Indian Department. Iron ores, chiefly earthy-brown hæmatite and magnetic iron-sand, occur abundantly in several parts of India, and have been smelted, from time immemorial, by the natives, in small furnaces. The East Indian Iron Company, No. 3, sends an instructive collection of iron ores and the various products which they yield. There are several blast furnaces in India on the European model, using charcoal as fuel. An excellent series of the various kinds of iron-sand smelted by the natives will be found under No. 10. It is a remarkable fact that in one locality in the Nerbudda Valley, good bar-iron, but only in small pieces, can be made and sold by the native smelters under 5*l*. per ton. But the selling price of native iron in most parts of India is generally about double this sum. In the native process the iron is obtained direct from the ore in the malleable state, and pig-iron is not formed. All iron was formerly produced by this direct method; and to this day it is still practised in the Pyrenees, Finland, and some of the northern parts of the United States.

In the official catalogue only three numbers appear in Class I., and occur in the department of the United States. There is a good series of American minerals, including specimens of Lake Superior copper. Fine spiegeleisen from New Jersey Franklinite, a zinciferous ore of iron, is exhibited. The ironmaking resources of the United States are very great, and, it is scarcely necessary to observe, are not represented in the present Exhibition.

There is scarcely a department in the Exhibition in which some iron ore may not be found; but we believe that we have called attention to all the iron ores which seem to be practically valuable. We shall next proceed to a connected review of all the objects in the Exhibition specially illustrative of the metallurgy of iron. — *Times*.

In the last three years 590 proposals and plans for the purposes of shot-proof ships have been sent in to the Admiralty. They were all referred to the Controller of the Navy and the assistant officers of his department, and only 105 of them reached the further stage of being submitted to a committee or referee; 37 are still under consideration.

ON STEAM-BOILER EXPLOSIONS.

The following is an abstract of the paper read before the members of the Institute of Mining Engineers by Mr. Stephen S. Crone, M.E., of the Killingworth and Seaton Burn Collieries, "On Steam-Boiler Explosions:"

The serious and disastrous consequences usually resulting from steam-boiler explosions were of such an important nature as to require the closest investigation, as under the most favourable circumstances they are generally surrounded with difficulties, and attended with results which, in the present state of our knowledge of the subject, it seemed difficult to account for in a clear, practical, and satisfactory manner. Mr. Crone proposed giving a minute descriptive account of the accident, as a record of facts, to aid those interested in the investigation of these, to say the least, mysterious occurrences, which ever ought to be carefully enquired into, and their attendant consequences, to endeavour, as far as possible, to arrive at the true source of the accident.

The boiler which exploded (No. 4, at Seaton Burn,) was 32 ft. long, 6 ft. 8 in. diameter, working at a pressure of 35 lbs. to the square inch, being one of six large cylindrical boilers, varying from 32 to 35 ft. long, coupled together with 8-in. steam pipes. There were two ranges of feed-pipes, two safety-valves, two floats, one of which was an alarm whistle float. The boiler mountings were constantly examined, and kept in proper working order—everything calculated to guard against accident. The boilers were also attended to by steady, experienced men; but, from some unexplained cause, the plates of the boilers would seem to have been over-heated, and the explosion followed, with a fearful amount of violence—the boiler mounting about 120 ft. straight up into the air, and dividing into three portions, the main portion falling 97 yards to the east, a huge sheet, rent and ruptured in the most extraordinary manner, the fire end being reversed from its original position, evidencing an extra amount of force at that end, as the boiler must have turned round in its flight after leaving the boiler-seat. The second portion went more northward; and the third, a part of the fire end, went in an opposite direction to a distance of 76 yards, giving strong indications of having been ruptured with great violence. Sketches of these portions were laid before the Institute. The boiler-seats were shattered, blown down to the foundation, and as completely destroyed as if a mine of gunpowder had been sprung beneath them, and the boilers thrown about in various directions, the outside one turned bottom upwards. The boiler had only been at work one day before it exploded, after having a thorough examination, repair, and cleaning. The safety-valves, and other boiler mountings, had been stripped, cleaned, oiled, and everything done to make them efficient. The boiler was quite tight, and no leakage visible.

It was doubtful, from some unexplained cause, that the boiler had been deficient of water. The consequences might be something like the following:—The firing going on as usual, the upper portion of the boiler would become over-heated, especially from the edge of the water to the top of the flue; the tenacity of the plates would be weakened as their temperature increased above 550°, and the liability to rupture greatly augmented by the unequal straining of the iron consequent upon the temperature of one portion of the boiler being so different and variable from other portions; the steam and water would become surcharged with heat to a considerable degree above that indicated by the pressure of the steam—thus storing up power, whilst the plates were decreasing in strength, until some disturbing influence suddenly reduced the pressure of the steam from the surface of the highly-heated water, which may arise from the sudden opening of a safety-valve, or exhaustion caused by the opening of the steam stop-valve; by standing or starting the engine, or in cases similar to this, where a number of boilers are connected, such, perhaps, not supplying a uniform quantity of steam; by a sudden draught of steam to the engines working; or, finally, by the gradually weakening

plates of the boiler at last giving way, and splitting open at a weak joint.

Upon examination after the explosion, no part of the plates measured less than $\frac{3}{8}$ in. thick, but from the exposure of the rivets and fractured seams it was evident the boiler had been originally of defective construction. The rivet holes were not opposite each other, and had been picked or cut out into an oval form, and forcibly drawn together by means of drifts or pins, to get the rivets entered and driven up, irrespective of their being at right angles to the direct strain upon the joints. The immoderate use of drifts or pins, as well as excessive caulking, was a clumsy, injurious remedy to defective workmanship in the construction of boilers, and could not be too much censured. The forcible unequal strain and compression by those applications, as having all the effect of a wedge driven in, must cause lasting injury and constitutional weakness; the plates being injured near the edge, where they are least capable of resistance, and most likely to give way, and where, perhaps, they may be laminated and faulty by being pared or slabbed too near the edge. The effect of this is often seen by the plate cracking from the rivet holes, and fractures proceeding along the line of rivets for considerable distances, thus greatly augmenting the danger of accidents to boilers. This objectionable method had, no doubt, injured the plate, resulting in a point of very questionable strength.

Referring to the interesting experiments which have been tried as to the effect produced on water thrown upon red-hot plates taking the spheroidal form, the temperature of maximum vaporisation for iron has been variously stated from 300° to 350°, and the temperature for perfect repulsion of drops of water about 400°, at which temperature the water does not wet the metal under atmospheric pressure, but assumes the spheroidal form, or small spheres, enveloped in a thin coating of steam, having the power of reflecting the heat, and preventing immediate contact with the iron; the water in this form rolling about, with its elastic coating, evaporating very slowly, and not flashing into highly elastic steam, as might be assumed would be the case. But it must be remembered these experiments have generally been tried under simple atmospheric pressure. It is most remarkable these spheroids never reach a temperature of more than 205°. I think it may be doubtful whether inside a steam-boiler, heated to redness, this effect would be produced upon any large body of water at a high degree of temperature, and under the pressure of several atmospheres, as it may be assumed the pressure of the steam in the boiler would overcome the reflecting power of the spheroid when near the plates against which it might be dashed, and thus cause the sudden production of a large quantity of steam upon any disturbing influence putting the steam in motion, such as the opening of valves, &c., or even sharp heavy firing, causing the water to rise to a higher level than at the time the plates were heated. Whether this is the case with red-hot plates or not, it is certain that plates at a lower temperature, about 300°, which gradation must, of course, exist before the plates are red hot, are capable of producing steam in a most rapid manner, upon water being brought in contact with them, and thus cause the most serious consequences.

The result of boiler explosions generally indicated the exertion of such force and violence as to have encouraged the supposition that they must have been caused by some more explosive agent than steam, which, in ordinary everyday work, we hold so completely under control. Electricity and hydrogen gas have generally been selected as the forces most likely to produce such destructive effects, but how either the one or the other is generated we are left entirely to imagine.

A curious and uncommon circumstance had occurred at Seaton Burn about fifteen years ago. A boiler had been boiled dry through the failing of the feed: the engine, running all the time, exhausted the steam, until the supply failed, when it stopped, and could not be moved. The fire was withdrawn, and the boiler allowed to cool down. When a sludge-hole close at the bottom was taken off the following morning, and a lighted lamp held at the hole, a long flash of flame issued out four times, gradually retreating into the boiler, where it was soon consumed. No doubt a portion of the water had been decomposed, the hydrogen liberated, and the oxygen fixed with the iron; the former would get largely mixed with atmospheric air through the rivet holes and vents, which were loose and burnt, thus forming a weak explosive compound, which fired when it came in contact with the flame of the lamp. This boiler was quite new; had it been an old or weak one it might have given way and exploded.

Mr. Crone then explained the boiler fittings now in use at Seaton Burn Colliery. A blow-off pipe was particularly described. A pipe about 2 inches diameter was placed at the top of the boiler in a diagonal direction, within the boiler, to a point 1 foot beyond the end of the fire-bars. A small round hole was bored in the pipe, a little above the lowest working line of the water in the boiler. The pipe outside the boiler was bent down into the fire-hole, in which was placed a cock, easily accessible to the fireman: this cock required to be turned frequently, at short intervals, say, every half hour: when turned, the water and mud were blown out from the bottom, and the steam pressing the water towards the small hole at the top, made a whirlpool, which drew the skum from the boiler, and blew it out above. Should the water be below the hole at top, of course, nothing but steam issues, thus indicating unmistakeably that the water is low, and becomes a good check upon the floats. This was called a blow-off, skimming, and gauging pipe, and is a remarkably useful and inexpensive application. One party who had used it was compelled, previous to placing the pipe upon his boiler, to clean it out every month, when about an inch of mud was always taken out: after using the blow-off pipe the boiler was opened out, and found quite clean. It has gone for eight months, and is still clean when opened out.

It was reasonable to anticipate that boiler explosions might, at least, be reduced in number, by the boilers being well constructed, and of good materials; the working steam pressure regulated to suit the nature and character of the boiler, and reduced as it may get deteriorated by age and wear; boilers carefully used, cleaned, and examined throughout by careful, competent workmen, every time they are opened; the mountings of such a form as effectually to perform what they are destined to do, and examined at short periods—every hour or less; the feed-water regulated by careful and trustworthy men; safety-valves closely examined, and firing regulated to requirements of engines. These arrangements, carefully attended to, may at least insure comparative safety.

THE HOUSE OF COMMONS AND THE ARMSTRONG GUN.

On Monday last the attention of the House of Commons was called to the condition of the country in its relation to the Armstrong gun.

Lord H. LENNOX said, the item he particularly wished to refer to was that for Armstrong guns, which was included in Vote 13 for land and sea services. It would be in the recollection of the House that on Friday last his hon. friend the member for Liskeard (Mr. B. Osborne) asked whether it was true that the second large Armstrong gun had been loaded with 10 lb. plus powder, and that it burst on being fired, and had been rendered unserviceable. He added that, if that were the case, he thought a committee of scientific men should be appointed to test the principle on which the gun was made. The Secretary of State for War replied that it was perfectly true the gun had burst and was unserviceable, but declined to grant any further enquiry. Since that time circumstances had come to his knowledge which justified him (Lord H. Lennox) in bringing the matter again before the House, and asking the Government for information. The House was probably aware that the French had an admirable system of testing their artillery, and that they not only ascertained the gun's power of resistance from within, but its external power of resistance—that they not only shot *from* a gun, but *at it*. Many of the most experienced artillerists of this country had been for some time aware that the very fact of the Armstrong guns being so powerful in sending a shot rendered them peculiarly liable to injury from almost trifling blows from without. The Government, as he understood, being perfectly convinced of the justice of these representations, were obliged to institute an investigation, and he wished to ask the Government whether the following questions were true:—Whether the trial was made by throwing grape shot from 32 and 68-pounders at a range of 300 yards, whether sixty rounds were fired in that way at the range of 300 yards, which was the extreme range for grape shot, and only three guns were hit, and whether each of those hits did not prove totally destructive, or did not materially injure the Armstrong guns, which were of various calibres. If that information were true, considering that the test was applied in the most favourable way to the Armstrong guns, the ordinary range for grape shot being 150 yards, and that those guns had proved a signal failure, he would ask the Government whether they did not think a committee or commission of scientific men ought to issue for the purpose of ascertaining the reasons for these failures. Some 5,000 artificers were employed in making the Armstrong guns at a cost of some 10,000*l*. weekly, and if the system went on without further enquiry, and the guns should turn out to be an utter failure, that would be an immense cost to the country in wages alone.

Mr. OSBORNE said the question was important, and as the House was about to separate an answer was due from the right hon. gentleman, the Secretary of War, to his noble friend. He thought the House should take into consideration, before separating, the enormous sum of money that had been expended on a weapon that was not yet proved to be effective. The fact was, that at that momont they were not in possession of a naval gun that would answer their purposes. A gun recently tried with 25lb. powder had burst, and he asked the right hon. gentleman why he would not appoint a committee of skilled officers and mechanicians to enquire into the construction of the gun, and satisfy them of the cause of failure?

Sir G. C. LEWIS said that he had carefully considered the question put to him by the noble lord the member for Chichester, and he could only repeat the answer given by him on a previous day, that the select ordnance committee seemed to him quite sufficient for the purposes they had to effect. His noble friend said the Armstrong gun had been proved to be a failure; that was an assertion very easy to make, but he (Sir G. C. Lewis) knew that it had been proved to be successful.

Mr. OSBORNE: Where?

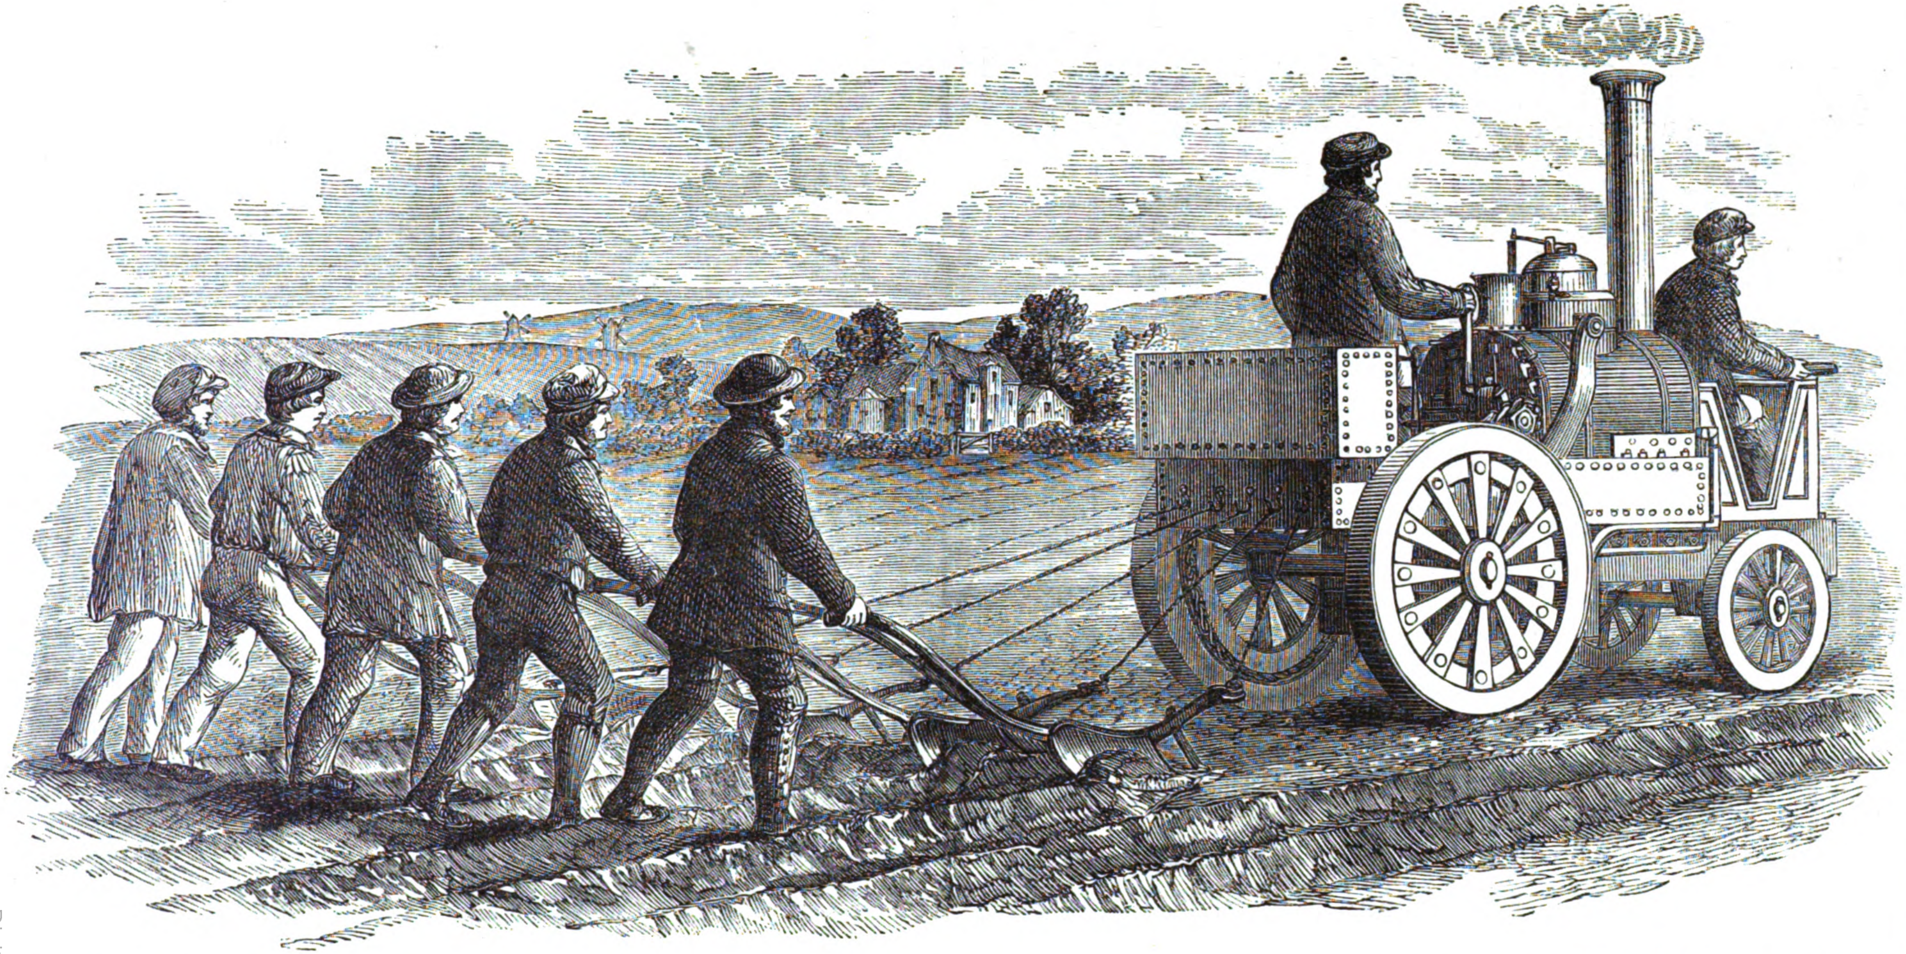
Sir G. C. LEWIS: In the experiments that have been made.

Mr. OSBORNE: As a naval gun?

Sir G. C. LEWIS: The Armstrong gun, as a naval, field, and garrison gun, has been proved to be the best gun hitherto produced. He did not deny that improvements might be introduced, but to describe the Armstrong gun as a failure seemed to him to be an entire distortion of the facts. A committee had already enquired into the subject, and professional witnesses competent to give an opinion were examined. He had recommended that the committee should be re-appointed next session, and that should satisfy the House that this important subject was not lost sight of by the Government.

Mr. MONSELL said that it was admitted that they had no gun at present that could do serious injury at 200 yards to an iron-plated ship. That was the reason the hon. member for Liskeard said the Armstrong gun was a failure. He meant to say that it did not effect all that was necessary to be done for the efficiency of the service. It was well worthy the consideration of the department in charge of this matter, whether some steps should not be taken that would admit the scientific intellect of the country to devote itself to this momentous subject in the most practical and efficient manner.

GILES'S STEAM BULL.



In order to render intelligible the peculiar construction of this engine and the difference between it and all other engines which have been invented for the purposes of road and agricultural traction, we must examine the character of that mechanical effort which constitutes the drawing power of an animal. The principle is the same in both the biped and the quadruped; but is more simple in application and more easily recognised in the former than in the latter. When a man undertakes to draw anything behind him, or to push anything before him, he throws the weight of his body forward, and the amount of propelling or drawing force which he exerts is due to the angle of inclination which the body assumes (measuring from the resting-point, the foot). The purpose which the foot effects in this effort is not that of *traction* but of supporting the weight of the body in such a position as may most effectually develop the tractive power due to *gravity*. The muscular power is employed to constantly maintain this position, and it acts in a line directly between the foot and the centre of gravity. It therefore is not the foot which draws; but the drawing power is derived directly from the weight of the body thrown forward in the direction in which the drawing power is expressed. If a man were forced to stand upright, that is, if the centre of gravity of his body were perpendicular to his foot, he could exert no pulling force, and it is the same with the quadruped.

All engines previously constructed have had their tractive efficiency based alone on *friction*; that is, the centre of gravity is brought over the driving wheel, and the adhesion to the surface (over which the engine travels) is due solely to the hold which is afforded by the circumference of the wheel rubbing against the ground.

In Giles's engine the direct agent of traction is gravity, friction being used only as a foundation on which to develop a far higher and more efficient principle of adhering to the surface of the earth. The wheels of the engine merely carry its weight, while the tractive effort is the combined operation of the two forces in action, viz., the power of the steam and the law of gravity.

The application of this principle to the science of locomotive mechanics opens up an entirely new field for the enterprise of engineers, as well as the capital and industrial interests of the nation, only limited in its extent by that of the untilled and untrodden world. By its agency iron and steam can overcome all tractive operations now performed by animal labour with the utmost reliability and success.

An engine constructed on this principle can now be seen in operation on application to the inventor,

John Giles, 69 Basinghall Street.

HOT-WATER CIRCULATING APPARATUS FOR WARMING PURPOSES.

By Mr. Purnell.*

FIG. 1

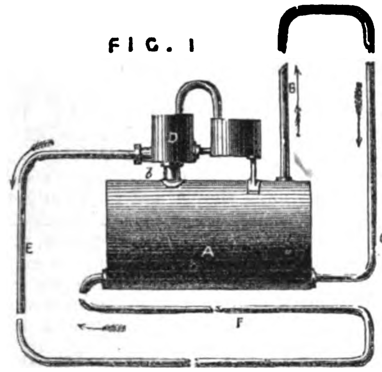


FIG. 2

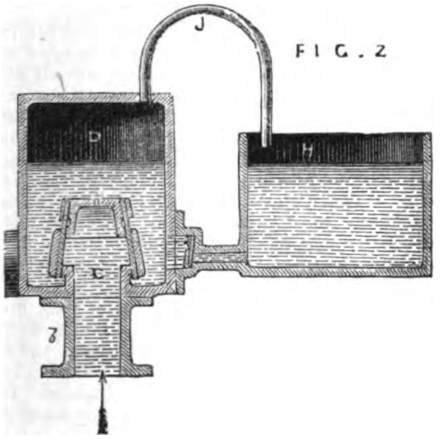

Fig. 1 is a diagram, and fig. 2 is an enlarged section of the principal part of the apparatus.

Ordinarily, hot water is made to circulate through pipes by placing the boiler A, fig. 1, at the lower end of a range of pipes, B and C. The water in the boiler, and in the pipe B, from the top of the boiler, becomes heated, and slightly lighter than that in the return pipe C, which communicates with the bottom of the boiler. The cooler and heavier water tends continually to displace the warmer and lighter, and a circulating current in the direction of the arrows is thereby induced and kept up. In this arrangement the pipes are entirely, or for the most part, above the level of the boiler; but if the pipes were for the most part below that level, the circulation would not (with ordinary arrangements) take place, as the warm lighter water in the descending branch could not force up the cold heavier water in the ascending return branch.

It is often extremely inconvenient to find a proper place for the boiler sufficiently below the general level of the pipes; and some simple means to cause circulation to take place in pipes on or below the level of the boiler has been a great desideratum.

In Mr. Purnell's arrangement, a pipe, *b*, from the top of the boiler, A, communicates with a valve box, D, from which there proceeds the descending or out-going branch, E, the ascending return branch, F, communicating with the bottom of the boiler. In the box, D, there is a pair of simple, freely-working clack-valves, G, which the water has to lift in passing from the boiler to the branch E. To keep up the supply of water, there is a cistern, H, communicating through a clack-valve with the box, D; and this cistern may itself be kept full by an ordinary float-cock on a service pipe. The box, D, is open to the atmosphere by the pipe, J, which is bent over to the cistern merely to catch any dripping from condensed steam.

The working model was contrived so that it could be arranged with either the old or the new arrangement, and it was shown that with the old arrangement no circulation took place in the pipes, whilst with the new plan a regular continuous circulation was at once established, the pipes being below the level of the boiler in both cases.

After trying a great many different plans, the present one was at length arrived at by Mr. Purnell; but it is not easy to explain how the action takes place. In the working model the box, D, was formed with glass sides, through which it could be seen that the valves did not remain steady, but were in a continual tremor. Indeed, without an intermittent action it is difficult to conceive how the result obtained could be produced. The opening of the valve indicated a temporary increase of internal pressure, which would give the water a tendency to leave the boiler by both branches, E and F. If the water were previously quiescent, the exit would actually be freer by the return branch F, the valves obviously offering some slight resistance the other way. If the water were already in motion in the pipes, the tendency would take effect in slightly retarding the entrance of the water into the boiler by the return branch F. The next step of the action is the closing of the valves, which must be due to a diminution of the internal pressure, and the water must tend to return into the boiler, but being prevented from returning by the valves by the branch *b*, must do so entirely by the branch F, and so the circulating current is gradually established. The intermittent variation in the internal pressure has yet to be explained; but it appears that, however regular the fire is, the intermittent or pulsating action exists. The model boiler was heated by a gas jet, the heat from which is perhaps as regular as can be obtained.

In reply to enquiries, Mr. Purnell further explained the details of his apparatus, and stated that he had it in operation on a large scale in different warehouses in Glasgow, and also in garden hothouses. A very convenient application of it was where it was wanted to heat a single flat of a building. Formerly the boiler had to be placed in the flat below, which might be occupied by a different tenant; but with his arrangement the boiler might be placed on the same flat with the pipes below it near the floor, and even beneath the floor, where required.

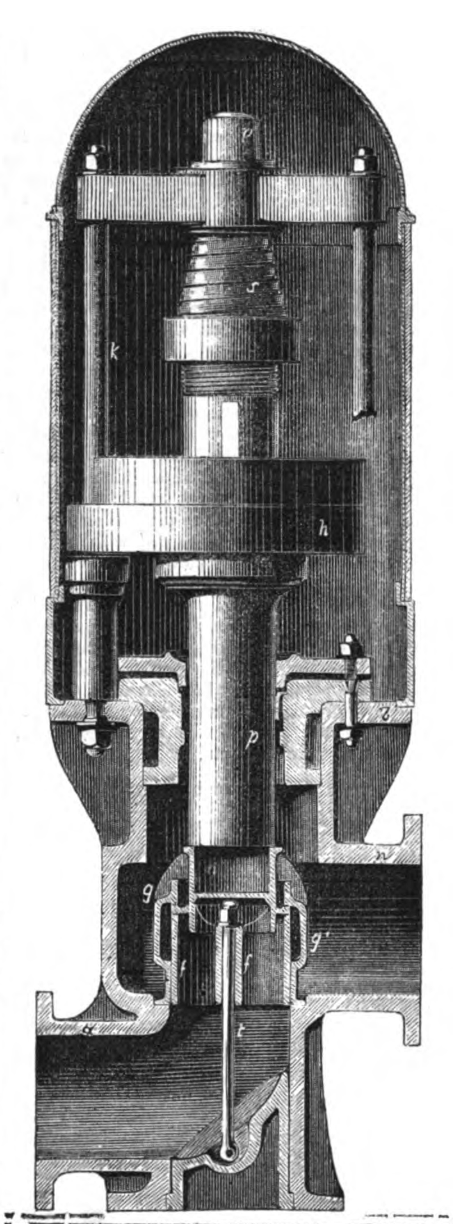
* Paper read, and a working model shown in operation, at the Institution of Engineers in Scotland.

HUSBAND'S IMPROVED WATER-VALVE.

Engines for pumping or forcing water are frequently subjected to great danger by reason of their load being suddenly withdrawn, either on account of the bursting of pipes or breakage of their joints, or other causes, the consequence of which is, that the working parts of the engine and pump being unexpectedly relieved from the opposing pressure of water on the plunger, acquire a velocity of motion sufficient to cause serious damage and destruction to the entire machinery.

The invention illustrated below, which has been recently patented by Mr. W. Husband, of Hayle, Cornwall, has for its object a means whereby, in the event of the accidental removal of the load from the engine, another load is substituted, which controls the speed of the engine and prevents the results above mentioned.

At a short distance from the engine, and to the pipe leading therefrom to the main along which the water is to be forced, an elbow joint *a* is to be bolted, on the upper part of which, by means of suitable flanges and bolts, a bed plate *b* is fixed, on which four standards *k* are secured at equal distances apart, their upper extremities being firmly fixed in position by means of a crosshead *c*, which is provided with a slot in the centre, in order to allow of the vertical movement of the guide rod of a plunger *p*, which passes down between the standards and through a stuffing box on the bed plate into the upper portion of the elbow joint, around the interior of which, on a level with the upper portion of the pipe from the engine, the stationary parts of the valve are fixed, consisting of vertical arms or plates, on the top of which a circular ring or plate is secured, having its opening situated directly beneath the plunger



or pole, which is made so that it may, when desired, fit thereon and form a water-tight joint. Above this circular plate, or what may be termed the bed on which the plunger or pole descends, and bolted or otherwise secured to the sides of the plunger, are four or six arms *g*, of a curved form, which extend outwards and downwards beyond the plate, in order to be attached to the vertical slides of the valve, which are thus opened and closed simultaneously with the valve which the area of the lower surface of the pole forms with the circular plate, which latter is to be furnished with arms, brackets, or other supports extending from its lower surface near the opening to the edge of the pipe, or to the lower portion of the fixed vertical slide valves.

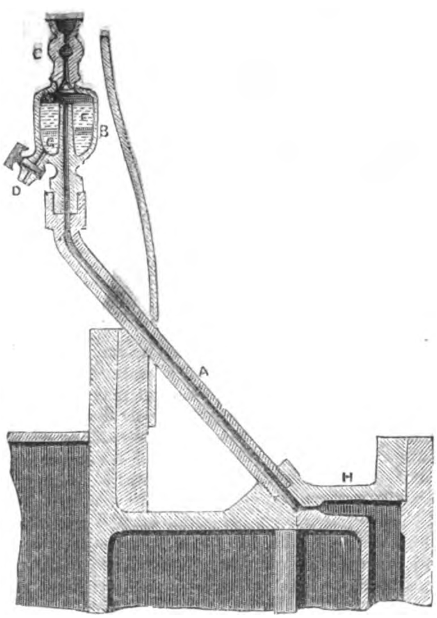
The operation of the apparatus is as follows:— When the engine is to be started, or when the pressure of the water in main idea is ascertained, the pole or plunger is to be weighted as follows:—It is provided at a short distance above the stuffing-box with a fixed circular table *h*, to sustain a series of weights *i*, in the form of discs, having a channel cut therein, which enables them to be placed around the pole one on the other. The table has four projections furnished with slots, which enable it to slide vertically on the standards by the action of the pole, and it is controlled in its descent by means of a flange covered with india-rubber, on each of the standards a short distance below the projections, whereby the jar caused by the sudden

descent of the table and pole is modified, thereby relieving the valve from unnecessary shock. The table is to be weighted so as nearly to equal the pressure of the water upon the area of the pole or plunger; the consequence will be that the pole and system of valves will be raised by the pressure of the water, and a free opening will result for the passage thereof from the engine along the main pipe *n*; but in the event of any accident occurring to the main pipe, whereby the pressure of the water is suddenly taken away from the engine pump, and which would, in the ordinary course of operations, entail such a rapid motion of parts as to cause destruction to the machinery, the pressure is instantly removed from the area of the pole or plunger, which then descends and closes with it the system of valves, thereby throwing the whole load of the weighted plunger upon the engine and pump, and controlling them from the destructive speed they would otherwise acquire.

The plunger or pole may be used in conjunction with the circular plate, and form a valve, without the addition of the vertical slide valves; in some instances where there is not much pressure of water, or where the size of the pipes is small; and the elbow joint may be dispensed with in these instances. The stationary parts of the valve are to be held in position by a screw bolt or rod and nut *t*, as shown. A spiral spring *s* is adjusted to the upper part of the pole, and bears against the under side of the cross-head, thereby easing and assisting the motion of the plunger and valves. The entire apparatus may be enclosed in a casing, with a cap or cover, as represented on p. 67, which may readily be removed when it is required to lubricate or repair the parts.

LUBRICATING APPARATUS FOR LOCOMOTIVE AND OTHER STEAM ENGINES.

By Mr. Patrick Stirling.*



The object of the lubricating cup is to feed oil gradually to the slide-valves of locomotive engines working under high pressure steam. The lubricating cocks generally in use deliver their contents in a few seconds, and the oil or tallow let in is necessarily blown away rapidly, and the valves and cylinder faces left to work dry after a very few strokes.

Mr. Stirling's attention has been drawn to this matter from the frequency of valves and cylinder faces getting cut up, particularly the upper edges, where there is a difficulty in getting oil applied; and to diminish this evil and provide a remedy, this lubricating cup was designed.

The engraving shows a section of the cup as applied to the valve-casing of a locomotive engine cylinder. The syphon-pipe, A, between the cup, B, and the edge of the slide valve, I, is open throughout. The top of the cup is furnished with an ordinary stop-cock, C, for the purpose of filling it with oil. It will be seen that the steam when let on to the valve-casing, H, has free access to the top of the cup, which immediately acts as a surface condenser, and the water, G, so formed collects slowly in the cup, and by reason of its greater specific gravity descends below the oil, F, and by raising it to the top of the syphon-pipe, A, causes it immediately to flow down the tube to the upper edge of the valve.

Cups of this description have been in use for some time past, and have been found to work well. The time occupied in emptying out the oil has been half an hour.

The small cock, D, at the bottom of the cup, is for emptying the water after the oil is exhausted.

It is evident that the lubricator can be made available in a variety of situations, and also that its powers of delivery can be increased to any extent by enlarging the size of the cup.

The advantages to be derived from this lubricator are chiefly the extended period during which the oil is delivered, which has the effect of keeping the slide-valve and cylinder perfectly well lubricated, and the valves are much more easily driven, and therefore the tear and wear upon the valve gearing is greatly diminished.

Mr. Stirling stated that the invention was not patented, and that he would be happy if anyone would make use of it.

* Paper read at the Institution of Engineers in Scotland.

CAPTAIN CUNNINGHAM'S METHOD OF PROTECTING SCREW-PROPELLERS.

Mr. H. D. P. Cunningham, the inventor of the "Cunningham system of reefing topsails from the deck," has just completed a patent for protecting the screw-propeller from fouling or entanglement by hawsers, ropes, &c. There can be no doubt but that the danger of entanglement of the screw-propeller of a war steamer is a very valuable point in her character, and it is possible that mechanical means could be designed for purposes effecting the fouling of the screws of war steamers in action. Once render a ship of this kind motionless, and her condition would be of a very helpless kind, especially should she not be provided with masts and sails, as it is contemplated in the case of ships on Captain Cole's plan. Means, therefore, for protecting the screw from fouling appear to be an indispensable provision for war steamers, and yet, curiously enough, this consideration appears to have been almost neglected. Our war steamers are without any means for protecting their screws. Mr. Cunningham appears to have had this point particularly in view when he designed his apparatus. He alludes in his specification to two modes of carrying out his design. One consists of a very simple application for protecting the screw from hawsers or underlying ropes — that is, ropes or hawsers extending under water at such a depth as, when run over by the ship, especially in a fore and aft direction, are instantly fouled by the screw, and hawsers purposely laid out at or near the surface of the water for fouling the screw of an enemy's ship of war. The other arrangement contemplates the protection to be of a more complete character, such as for protecting the screw against wreckage alongside caused by the falling of masts, &c.

Nothing can be more simple than the first of these plans. Upon the after stern-post, or dead wood, Mr. Cunningham places a radius bar working upon joints fixed to the post. The end of this bar is bent round to accommodate it as nearly as possible to the shape of the tuck of the stern, and when turned off, enables the apparatus to be dipped below the axis of the screw. One or more chains extend from the end of this bar forward to where the run of the ship commences. Another chain stretches up to the counter, acting as a suspensor to the bar when lowered down; another extends from the extreme of the curved end to the heel of the stern post, whilst another extends up over the stern. Thus the screw propeller is enclosed in a guard in every direction against the approach of a hawser or rope. When not required for use, as for example at sea, and no chance of encountering ropes, &c. in the water, the radius bar is triced up, and, being made of flat iron, lays up and down the stern post, offering little or no impediment to the progress of the ship. The action of the raising of the bar raises also all its attachments out of the water, so that the ship is as free from impediment as an ordinary vessel. Nothing can be more simple and apparently effective than this application against the particular cause of fouling a screw — a cause, by-the-by, also of frequent occurrence to merchant steamers going in and out of docks and harbours, which are frequently detained a tide by taking up an underlying and unseen warp in their propeller, but which, by Mr. Cunningham's most simple application, can steam out of any dock, however fouled with warps and hawsers, with perfect safety.

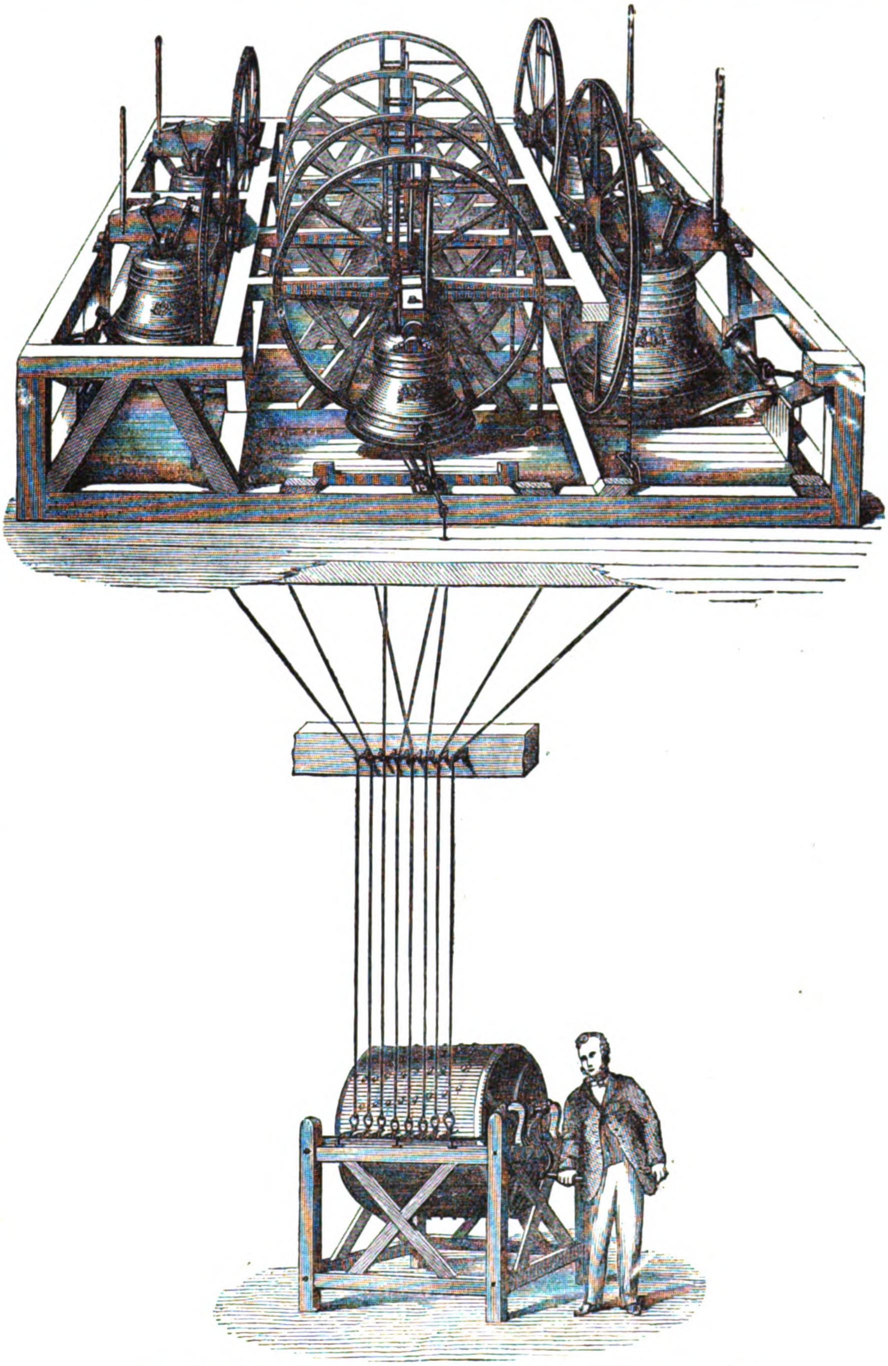
The other arrangement alluded to consists in applying a netting, or an increased number of chains or flexible bars to the means already described, and which additional applications are removed out of the water when not required for use by the same action of the radius bar. The protection afforded by these additions is very complete, and Mr. Cunningham contemplates that, in the event of a ship losing a mast either in action or otherwise, the wreckage will be effectually kept clear of the screw. It is generally supposed that the cutting away of the mizen-mast of the Prince screw steam transport in the memorable gale off Balaklava was the cause of the loss of that ill-fated ship. It was known they were using their steam power at the time to ease the cables, and it is believed the rigging was instantly taken up by the screw, which was thereby rendered useless. It has also been believed that, at the time the masts of the Royal Charter were cut away, she was easing her cables with the screw, and the assistance of which ceased by the rigging fouling the screw. In action, too, the loss of masts would create the greatest possible danger to the screws, not only to the ships losing the masts, but also to other ships present running into the wreckage. The subject, therefore, taken up by Mr. Cunningham is an important one, and the simplicity of the means which he provides for accomplishing his object encourages the belief that his plan is a practical one, and that it will be attended with success. The trials already made in a small screw vessel at Portsmouth are reported to have been very successful.

NAVAL REFORM.

On Tuesday evening last, in the House of Commons, Sir M. Peto moved that, in the opinion of the House, it was the duty of the Government to prepare a measure for the reform of the naval administration. The commissions and committees which had sat since the Crimean war on almost every department of the navy showed that great dissatisfaction existed with the present naval administration, and that some change was necessary; and many speeches which had been made in that House testified to the same effect. The Government had no choice but to consent to the select committee on naval administration, which examined thirteen witnesses and published their evidence, but made no report. Not two of the official witnesses agreed; but the non-official naval men all agreed on one point, that the present system of naval administration was hopelessly and irredeemably bad. The first and chief witness, the Duke of Somerset, gave reasons for and against the enlisting system, and thought the balance to be in its favour. The right hon. baronet further quoted the evidence of Sir J. Graham, Sir F. J. Baring, Sir Charles Wood, and Sir John Pakington; and then, summing up, he said that Sir J. Graham was in favour of the existing system; Sir F. Baring favoured a board which, however, he said, might mean anything; Sir Charles Wood

was in favour of the existing system, with power vested in the First Lord to remove the junior lords and to abolish the secretaryship; and Sir J. Pakington was entirely opposed to any board, and he approved of the entire system. After quoting the evidence of several admirals, the right hon. baronet said, that in the thirty years ending in 1859, there had been seventeen changes of the First Lord, the average duration of the term of office of each lord being one year, ten months, and two weeks; and the total number of changes, including that of the secretary, was 103. In the last eight years there had been five changes in the office of First Lord, and thirty-four amongst the junior lords. How was it possible for persons holding office for such short periods to become acquainted with their business? There had been a committee upon dockyards, none of whose recommendations had been carried out. During the last fourteen or fifteen years, he had had to do with works which involved the expenditure of 49,000,000*l.*, and considering he had had experience in the organisation of large establishments, and, having gone through the dockyards, he declared that it was impossible that anything could be worse administered in a commercial point of view. The right hon. baronet then contrasted the naval administration of France with that of this city. The Emperor appointed a committee, which sat up to 1852, whose report of 1,500 pages he (Sir M. Peto) recommended to the attention of the Admiralty, and whose recommendations the Emperor had liberally carried out. That report declared that a country with less resources than England, if they were properly organised, would prove the victor on the day of trial. The Minister of Marine and the Marine Constructor of France were selected solely for their ability. The latter officer was the first to call attention to the impending change from wooden to iron navies. One vessel was built in France on trial, and ten then ordered like it; but, in England, the Warrior and the Black Prince having been built, ten or twelve of different descriptions had been ordered that it might be seen which was the best. The French committee also made recommendations as to dockyards, which were being carried out. After the return of the two Houses from Cherbourg, Lord Derby passed the severest censure on the Admiralty by forming another board, on whose report ten first-class wooden vessels were added to the fleet. (Hear, hear.) The extraordinary thing was, that, in the teeth of statements made in the report, such a recommendation should have been made and then acted upon. Such a state of naval administration must command the execration of the navy. The evidence further showed that there was no science in the Admiralty. Sir Baldwin Walker and Admiral Robinson had abundantly proved this. Then there was also a great deal of patronage at the Admiralty.

At this point the Speaker's attention was called to the fact that forty members were not present. Only thirty-two members being found present, the House stood adjourned at twenty-five minutes to eight o'clock.



A Peal of Eight Bells, with Chiming Apparatus attached, as exhibited in the Transept of the 1862 International Exhibition.

WARNER'S BELL-CHIMING APPARATUS.

Messrs. John Warner & Sons, bell and brass founders, 8 Crescent, Cripplegate, having had frequent enquiries for a machine by means of which a peal of bells might be chimed by one man, have recently manufactured an apparatus for this purpose, and which is now exhibited by them in connection with a peal of eight bells in the South-East Transept of the International Exhibition. The size of the largest or tenor bell is 48 inches, its note E, and its weight about 18 cwt. 3 qrs. 20 lbs.; the whole peal weighs about 86 cwt. The chiming apparatus, which is fixed in a pit sunk beneath the floor, consists of a drum made of bars of wrought iron, about ¼ inch apart, and between these are fixed a number of tappets or teeth. When the drum is made to revolve by means of the handle and screw, these tappets catch and draw down the wrought iron levers which are fixed on the frame of the apparatus, and which are connected with wires to the spring hammers fixed on the bell-frame. The levers being drawn down, the hammer is raised, and falls when the tappet releases the lever. With this simply-constructed machine a lad may correctly play a great variety of chimes upon six, eight, or more bells, though he may have no knowledge of musical time. Where required, the apparatus can be made to play several tunes on peals of eight or more bells. This machine is not intended to do away with the manly exercise of ringing, but is adapted for those churches where good and steady ringers cannot always be obtained; and having this idea in view, Messrs. Warner & Sons have so arranged the hammers that they in no way interfere with the wheels or other fittings, but the peal can be rung at any time when ringers can be obtained. From the simplicity of its construction, and the ease with which it can be fixed, it is recommended for our colonies. The peal, with the fittings, frame-work, and chiming apparatus, now in the Exhibition, have been purchased for the cathedral at Auckland, New Zealand. We may also mention that a prize medal has been awarded by Her Majesty's Commissioners to J. Warner & Sons, "for excellent workmanship and ingenuity applied in chiming bells by machinery." The working of the machine can be seen at the International Exhibition, as an attendant is always present, and chimes the whole peal at 12 noon, 3 P.M., and 6.30 P.M.

The same firm who exhibit this peal have recently cast a bell in memory of the late lamented Prince Consort, the inhabitants of Clyst St. George, Devon, having subscribed to purchase a bell for that purpose. Beneath a medallion-portrait of the late Prince runs the following inscription:—

IN MEMORIAM ALBERTI .
CONSORTIS . REGII .
PII . BENEVOLI . DOCTI .
BONARUM . ARTIUM . PATRONI .
OMNIBUS . DESIDERATISSIMI .
MDCCCLXII . .

BRUNEL'S MISHAPS.

ALTHOUGH Brunel died at the comparatively early age of fifty-three, it is even matter of surprise that he lived so long. He had more perilous escapes from violent death than fall to the lot of most men. We have seen that at the outset of his career, when acting as assistant-engineer to his father in the Thames Tunnel, he had two narrow escapes from drowning by the river suddenly bursting in upon the works. Some time after, when inspecting the shafts of the railway tunnel under Box Hill, he was one day riding a shaggy pony at a rapid pace down the hill, when the animal stumbled and fell, pitching the engineer on his head with great violence: he was taken up for dead, but eventually recovered. When the Great Western line was finished and at work, he used frequently to ride upon the engine with the driver, and occasionally he drove it himself. One day, when passing through the Box Tunnel upon the engine at considerable speed, Brunel thought he discerned between him and the light some object standing on the same line of road along which his engine was travelling. He instantly turned on the full steam and dashed at the object, which was driven into a thousand pieces. It afterwards turned out to be a contractor's truck which had broken loose from a ballast-train on its way through the tunnel. Another narrow escape which he had was on board the Great Western steam-ship, where he fell down a hatchway into the hold, and was nearly killed. But the most extraordinary accident which befell him was that which occurred while one day playing with his children. Like his father Sir Marc, he was fond of astonishing them with sleight-of-hand tricks, in which he displayed considerable dexterity; and the feat which he proposed to them on this occasion was the passing of a half-sovereign through his mouth out at his ear. Unfortunately, he swallowed the coin, which dropped into his windpipe. The accident occurred on the 3rd of April, 1843, and it was followed by frequent fits of coughing, and occasional uneasiness in the right side of the chest; but so slight was the disturbance of breathing that it was for some time doubted whether the coin had really fallen into the windpipe. After the lapse of fifteen days, Sir B. Brodie met Mr. Key in consultation, and they concurred in the opinion that most probably the half-sovereign was lodged at the bottom of the right bronchus. The day after, Mr. Brunel placed himself in a prone position on his face upon some chairs, and bending his head and neck downwards, he distinctly felt the coin drop towards the glottis. A violent cough ensued, and on resuming the erect posture he felt as if the object again moved downward into the chest. Here was an engineering difficulty, the like of which Mr. Brunel had never before encountered. The mischief was purely mechanical; a foreign body had gone into his breathing apparatus, and must be removed, if at all, by some mechanical expedient. Mr. Brunel was, however, equal to the occasion. He had an apparatus constructed, consisting of a platform which moved upon a hinge in the centre. Upon this he had himself strapped, and his body was then inverted in order that the coin might drop downward by its own weight, and so be expelled. At the first experiment the coin again slipped towards the glottis, but it caused such an alarming fit of convulsive coughing and appearance of choking that danger was apprehended, and the experiment was discontinued. Two days after, on the 25th, the operation of tracheotomy was performed by Sir Benjamin Brodie, assisted by Mr. Key, with the intention of extracting the coin by the forceps, if possible. Two attempts to do so were made without success. The introduction of the forceps into the windpipe on the second occasion was attended with so excessive a degree of irritation, that it was felt the experiment could not be continued without imminent danger to life. The incision in the windpipe was, however, kept open, by means of a quill or tube, until May 13, by which time Mr. Brunel's strength had sufficiently recovered to enable the original experiment to be repeated. He was again strapped to his apparatus; his body was inverted; his back was struck gently; and he distinctly felt the coin quit its place on the right side of his chest. The opening in the windpipe allowed him to breathe while the throat was stopped by the coin, and it thus had the effect of preventing the spasmodic action of the glottis. After a few coughs the coin dropped into his mouth. Mr. Brunel used afterwards to say that the moment when he heard the gold piece strike against his upper front teeth, was, perhaps, the most exquisite in his whole life. The half-sovereign had been in his windpipe for not less than six weeks! — "*The Brunels,*" *in the Quarterly Review.*

TO CORRESPONDENTS.

THE STRAIGHT LINE *VERSUS* THE WAVE LINE FOR VESSELS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—I do not wish to say anything uncivil, but I am constrained to request that Mr Moy would turn over the defence of the wave-line theory to some one more competent to discuss it, who can at least appreciate a mathematical argument, and not call it assertion. In the interest of truth and science in the abstract, but far more importantly in the interest of the practical science of ship-building, it is desirable, or rather it is a matter of the greatest consequence in the latter aspect, that this question of the propriety or impropriety of moulding the bows of vessels with hollow lines should be settled, one way or the other, I care not which. I have invited discussion upon the subject, not in reference to any mere assertions of mine, as Mr. Moy supposes, but in respect to the validity of my proof, that the accelerated motion of particles of water produced by hollow lines involves a greater expenditure of power than uniform motion in the same, as produced by straight lines. Scientific men have not yet come forward to dispute it, but it would be a matter for regret if Mr. Moy has stood in the way to prevent them. I have, however, observed that mathematicians, such as Mr. Macquorn Rankine and Dr. Woolley, for some reason or other, have appeared desirous of evading any decided expression of their thoughts on the subject, even when it has crossed their path; and yet I cannot but think that on such occasions it is only what we might expect from them, either to condemn or to give their hearty approbation to the theory, unless, indeed, they felt that they could not get up an opinion upon it, one way or the other. Respect and friendship are excellent things, and they have not been without influence upon myself, but no one sooner than Mr. Scott Russell would be ready to acknowledge that the public welfare is paramount.

The adoption of hollow lines is rather prevalent, and it is much to be regretted that it should be so, if the practice is bad. I admit, however, that it is just possible the practice is right, and that it is Mr. Russell's theory only which is bad. But then my theory must be bad also. Well, that does not necessarily follow; it may be deficient merely in the non-appreciation of obscure points in the physics of the subject, but which in practical results might override the tendency of what in the abstract is demonstrably true, and so bring about a contrary issue. It is this which is so frequently the cause of the discrepancy between practice and theory, and, along with other reasons, will ever justify caution, not to say suspicion, in regard to conclusions claiming to be rigorously and mathematically exact, if out of "the region of pure intellect." Now my proposition is, that whenever, as to *work*, the element of resistance increases in any ratio with the velocity, the addition of velocity avoidable under the given circumstances is a waste of power. And again, that water coerced into motion obliquely by a curved surface does impart that needless velocity; ergo, power is wasted, and the practice, as tested mathematically, is bad. But, nevertheless, is the practice bad? The argument, in its premises, and also in its conclusion, so far as the waste of power is concerned, is, I believe, unassailable; but as to the practical issue, might not a saving of power accrue in other respects from hollow lines which would more than compensate the loss? Might not, for instance, a less number of particles of water be put into motion? I do not believe that this can be proved, but I am desirous of learning what can be said on the subject; and no other course that I can conceive is open to the advocate of the wave-line theory.

Mr. Moy will excuse me from noticing his observations on uniform motion; they are, I can assure him, random remarks, without pertinency or point.

BENJAMIN CHEVERTON.

July 28.

THE ADMIRALTY, THE WAR-OFFICE, AND INVENTORS.

SIR,—Mr. W. Austin, C.E., in your last number, has ably exposed dereliction of duty by officials in the Admiralty. When, in the spring of 1826, at Richmond Barracks, Dublin, I practically proved the efficiency of my rifle percussion shell and elongated expanding shot, in presence of General Sir George Murray, at that time commander of the forces in Ireland, and numerous officers of the garrison, I obtained of him leave of absence to proceed to Woolwich, in order to prove the efficiency of my invention to the Select Committee there, Sir George observed to Colonel Farent, the Commandant of my regiment, the 34th, "The Committee will order answer No ... to be given to his invention."—I am yours &c.,

J. NORTON.

International Hotel, Bray, July 29.

Gossip.

On Saturday, the 21st of June, a respectable number of people collected at the Club House, Jersey City, U.S., to witness some experiments with Duffy's submarine gun. This gun is the invention of Joseph Duffy, of Paterson, N. J. The gun is placed on a deck in the vessel as far as possible below the water line, with the muzzle end passing through a stuffing box in the vessel's side. Mechanism is so arranged that when the gun is forced inboard by the muzzle coming in contact with the side of a hostile ship, the gun is discharged, sending not merely the shot, but also a considerable portion of the expanding gases, into the hold of the enemy's vessel. Valves are provided to prevent the ingress of water as the gun is driven inboard by the recoil. A small model was provided for the experiment, and was placed in the bow of a skiff, about 20 inches below the surface. The boat was rowed stem on against an oak target; and as the gun struck it was discharged, driving the shot through two 3-inch planks, and considerably shattering the target. The result was entirely satisfactory.

IRON SHIPS.—A correspondent of the *Devonport Independent* says:—"The condition of our iron ships, as from time to time they are brought under examination, is a subject for our gravest consideration. It was but a short time since we directed attention to the state of the plates of the bottom of Her Majesty's ship Triton, now being repaired in Keyham Yard, which were found to be so corroded by rust from the outside as to render it imperatively necessary to remove a large number of them. We have now an instance of the presence of the same insidious destroyer attacking an iron vessel on the inside, while externally she exhibited no symptom of decay. While the labourers in this yard, a few days since, were scraping the bottom of Her Majesty's steamer Princess Alice (the Admiral's tender at this port), a month or two since, a tender to Her Majesty's yacht, they found that in some places the scrapers went through the bottom; and on further examination it was discovered that the damage occurred to a considerable extent immediately under her cylinders, a part of the ship where, if the water had rushed through at sea, there would have been no means of stopping it, and the ship must have gone down. It was providential that the evil was detected in time. The shipwrights of the yard (and not boiler-makers) are employed in making good the defects by means of iron plates."

The Cape (Eastern province) Railway proposes an increase of its capital from 600,000*l.* to 1,200,000*l.* Its object, as the prospectus states, is "the construction of such railways in the Eastern Province of the Cape of Good Hope as the Colonial Government may sanction, under a guarantee of a minimum rate of interest of 6 per cent per annum."

The catalogue of the special exhibition of works of the Mediæval Renaissance and more recent periods, on loan at the South Kensington Museum, is now published, price one shilling.

In the House of Commons, on Monday night, Mr. Laird asked the Secretary to the Admiralty if the Admiralty had decided to build or alter any more timber vessels to be cased partially with iron-armour plating on Mr. Reed's plan until the Enterprise, now being altered, was completed and tried.—Lord C. Paget replied that one vessel was now being built upon the plan proposed by Mr. Reed, but he could not make any statement with respect to the future intentions of the Admiralty.

According to accounts received from Mr. Lange, the Suez Canal works continue to be pushed on with vigour. The breakwater at Port Said, which presented some difficulties, is now completed, and vessels are able to discharge their cargoes in all weathers. The jetty is being continued. Between the breakwater and the shore there remain about 1,800 yards to fill up, and the cargoes of large stone blocks daily sunk in the sea from the quarries at Mex are sensibly diminishing this distance. On land the progress in excavating the canal is alleged to be greater than is generally imagined. 25,000 men are engaged along the line, and the average quantity of earth removed is about 550,000 cubic yards per month. It is expected, therefore, that the works will soon be sufficiently advanced to allow the waters of the Mediterranean to flow into the basin of Lake Timsah. Meanwhile, a town is being constructed at Timsah, and workmen are employed in laying down the foundation for the quays intended for vessels to load and unload.

A telegram received on Monday announces the successful submersion of the first portion of a new telegraph cable between England and Holland. Owing to the increase in their message traffic between this country and the continent, the Electric and International Telegraph Company entered into a contract with Messrs. Glass, Elliott, & Co., of Greenwich, for a new line to be laid between Lowestoft and Landvoort. The steamer Hawthorne shipped 48 miles of the cable last week, and the whole was successfully paid out, under the superintendence of the engineers, Messrs. Canning and Clifford, and the electricians, Messrs. de Sauty and Saunders; the electrician of the Telegraph Company, Mr. C. F. Varley, being also on board. The cable is the heaviest yet constructed, and contained four conducting wires. The English shore end (15 miles) weighs no less than 16 tons per mile, and is above two inches in diameter. The remaining portion will be shipped immediately.

A Turin letter of the 16th July says:—"Two steam advice-boats, of 400 horse-power each, are now being built in England, and 4 iron-cased 26-gun frigates have been ordered in France. A contract has been signed with an English house for the construction of a ram vessel of 8 guns, of force enough to cut a line-of-battle ship in two. Contracts have been also entered into for the supply of all the projectiles of which the navy may stand in need. A purchase has been made of 3,000 revolvers and 10,000 rifles. The port of Ancona has been put in a complete state of defence; it contains 25,000 tons of coal and forty flat-bottom barges, each with two frigate anchors. The arrival of 300 pieces of cannon purchased in Sweden is expected in a few days, as well as 100 rifled cannon for the use of boats. The fine corvette Magenta, built at Leghorn, is about to be iron-cased, and the necessary plates have been purchased for three frigates now on the stocks—the Gaeta, Messina, and Prince Carignan. Fifty cannon have been purchased in America for the iron-cased frigates which are being built in that country for the Italian Government. Contracts have been signed for the supply of ship timber for this and next year."

A company has just been formed for providing a line of Express passenger steam-boats upon the Thames between Chelsea and Gravesend. These boats will be rather a novelty upon our river, as regards elegance and convenience, and will, we should think, attract a considerable portion of the passenger traffic from the over-crowded streets. In fact, to have accomplished this long ago, it was only necessary to have a line of vessels that would have pleased the passengers as well as paid the proprietors. If the new company study the one object sufficiently, they will accomplish the other also. The vessels plying above bridge at present are said to pay their small number of shareholders handsomely, and there can be no doubt but the new company will realise adequate profits, while their express passenger boats will be a great boon to the public.

On Tuesday Lord Bury announced that Her Majesty had assented to the appointment of a royal commission, in accordance with Lord Elcho's motion, for enquiry into the proceedings of the Royal Academy.

A company has been formed, under the title of "The Flintshire Lead and Zinc Company (Limited)" with a capital of 150,000*l.*, in 15,000 shares of 10*l* each, for the purposes of smelting ores of zinc and lead, and the manufacture of the products therefrom, on a large scale, in addition to Bennett's patent tinned lead pipes for water service. Extensive and commodious premises have been taken at Bagillt, in North Wales, the vendors having consented to take two-fifths of the purchase-money in shares, and not to receive any dividend until the other shareholders have received 8 per cent. out of the net profits. This property consists of 30 acres of land, held on lease, of which the works cover an area of two and a half acres, on which the necessary buildings for the carrying on the business is erected. The directors have in view the purchase of four other acres on the lower side of the works, and intend making such extensions as shall triple the present produce, which they affirm can be done at a cost of 20,000*l.* in the erection of additional machinery. [In the Mechanics' Magazine of March 21 we gave an illustrated description of Bennett's method of tinning lead pipes, to which we refer the reader.]

Since the burial of the great historian, near the Poet's corner of our national mausoleum, a piece of paper only, with the words "Lord Macaulay's Grave" written upon it, served to show where his remains were deposited. A tablet has, however, lately been placed over the grave. Unlike those recently let into the nave of the Abbey to perpetuate the memory of Mr. R. Stephenson, C.E., and Dr. John Hunter, it is devoid of all ornament, and bears the following simple inscription: "Thomas Babington, Lord Macaulay, born at Rothly Temple, Leicestershire, October 25, 1800. Died at Holly-lodge, Campden-hill, December 28, 1859. 'His body is buried in peace, but his name liveth for evermore.'"

In the House of Commons, on Monday, Lord Lovaine asked whether the electric light, now in use at Dungeness lighthouse, had been successful; and, if so, whether its adoption was to form part of the alterations contemplated by the Trinity Board in the Portland Lights. He also enquired whether there would be any objection to produce Mr. Faraday's reports on the light to the Royal Commissioners, and those made by order of the Trinity Board.—Mr. M. Gibson said the electric light had been exhibited for only a short time at Dungeness, but the result, so far, was encouraging. A proposal had been laid before the Board of Trade by the Trinity Board to reconstruct the lights at Portland, but the matter was still under consideration. There would be no objection to produce the reports referred to by the noble lord.—Lord Lovaine intimated that early next session he should call attention to this subject.

The last exhibition of German manufactures took place in 1854, at Munich. An arrangement had been made that the next should be held at Vienna in 1865. The Austrian Government has now declared its readiness to again give place to Munich, that city possessing all the accommodations necessary for such an exhibition.

The Empress of the French has presented the directors of the Lochlomond Steamboat Company with two splendid vases, as an acknowledgment of her deep sense of the kindness shown to her when she visited Lochlomond in November, 1860. The vases are of fine Sèvres porcelain, mauve-coloured, with burnished gold bands, and beautifully enamelled foliage and flowers, the blush-rose being most conspicuous. Each vase is two and a half feet in height, and three feet in circumference.

The *Derby Mercury* announces the important discovery of a continuation of the coal-field on the Coton Park estate, near the Gresley station of the Leicester and Burton Railway. It is a very valuable seam, of more than 13 feet thick at the depth of 160 yards. The bed of coal is identical with the main beds of the Moira and Gresley collieries.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

96. G. Hewitt. *Improvements in apparatus used in the manufacture of drain tiles.* Dated Jan. 13, 1862.

For the purposes of this invention, in order that the ends of such tiles may more advantageously than heretofore be made to go together with spigot and faucet joints, one end of each tubular tile is by the improved apparatus cut into the form of a hollow or concave cone, and the other end is cut to the form of a convex cone. The apparatus consists of two hollow conical cutters, one of which is fixed on a suitable handle, the stem of which enters into and fits the interior of the tile which is about to be cut at its ends, in such manner, however, as to allow of its being turned freely therein; as this fixed hollow cutter is caused to be rotated, and is pressed up towards the end of the tubular tile (which should still be only in a partially dried state), the cutter progressively removes the outer end of the tube, the shavings of the clay or brick earth passing through the hollow conical cutter from the interior outward. To facilitate the holding of the tile when being cut at the ends, the tile is placed in a hollow or semicircular trough, one end of which is bridged over with a semicircular arch, the outer surface of which, as well as the outer surface of the invert of the trough, is bevelled off so as to form a concave cone, suitable to admit of the use of the other conical hollow cutter, which is employed to cut the concave conical cut at the other end of the tile. The other end of the hollow trough or holder is formed convex, so that the fixed conical cutter by which the convex conical end of the tube is cut may pass on to the end of the trough or holder. *Patent abandoned.*

97. J. Betteley. *Improvements in ship-building.* Dated Jan. 13, 1862.

For the purposes of this invention, in constructing the ribs or framing of ships or vessels when iron is used planked over with wood, in place of using the sections of iron heretofore employed for the ribs or framing, the inventor employs iron of the following section, viz.:—Iron bars formed flat on the outer side or surface against which the wood is to be fixed, and formed on the inner side or surface with flanges at the edges, so as to give strength to the bars, and so as at the same time to render the inner side or surface suitable to receive the heads or ends of the bolts by which the wood planking is fixed to the ribs or framing. The planks at the outside of this framing are fixed in a direction from stem to stern or fore and aft; then a further planking is used outside or over the first-mentioned planking, and such second planking is to run in a vertical direction from the keel upwards, or it may run in a direction inclined to or diagonally across the previous or fore-and-aft planking; and such outer planking may be fixed to the previous planking by both, or in any convenient manner, and the seams of both the plankings may be caulked. In constructing deck beams and fastenings for wood ships it is preferred to employ two plates of iron kept at a distance apart by hollow distance pieces fixed by passing bolts or rivets through them at intervals along the beam. At each end of the beam the two plates are turned outwards from each other, and between the two plates of which a beam is constructed an iron knee is introduced at each end of the beam, and is fixed thereto by rivets or screw bolts. *Patent abandoned.*

98. T. W. G. Treeby. *Improvements in cannon and fire arms.* Dated Jan. 13, 1862.

In casting cannon the inventor produces the rifling in the following way:—The gun is cast on a hollow tube of the same twist and form as the rifling may be required, and, to prevent the tube being injured, he sends water through it, so that the rifling may be perfect. The tube may be removed or allowed to remain in the gun, and which would form an excellent casing, as the internal and external surfaces are of the same form. If breech-loaders are being formed, he passes a bolt at right angles through the rifling at the breech; if muzzle loaders, he stops the breech by a plug. The other part of the invention consists of a rifling machine. He has a rod or tube similar to the one before named, and by this application he produces a direct action, which is a great improvement over the machines now in use. *Patent abandoned.*

99. J. G. Marshall. *Improvements in the preparation of flax and other fibres previous to being spun.* Dated Jan. 13, 1862.

This invention consists in preparing the fibres of flax, hemp, and other analogous plants, by passing them in a wet state between a series of drawing rollers, to which an increasing draught is imparted, previous to being spun, and where all the fibres are reduced to one uniform length and degree of fineness. *Patent completed.*

100. C. N. May. *Improvements in the manufacture of pastry and in apparatus for the same.* Dated Jan. 13, 1862.

According to this invention the inventor makes the crust separate from the pie, making it of a suitable size to suit the pie dish, and raised in the centre, which form it keeps when

baked and placed on the pie. By this means a nice light crust is produced, and the pie rendered of handsome appearance. For this purpose he employs a plate of metal, or other material stamped up or otherwise raised of a suitable ornamental form, and on this he places the dough or paste, which plate imparts to the paste the raised form desired. *Patent abandoned.*

101. I. Carter. *An improved shaft tug or bearer used in harness.* Dated Jan. 14 1862.

This consists in dividing the tug or bearer, and hinging or jointing the same so as to allow of the shaft being easily placed in the tug and withdrawn therefrom, such tug or bearer being provided with a latch or bolt, whereby the end of the tug may be locked into a catch of brass or other metal or material, and thus form a complete ring, which, however, need not be perfectly circular in form. The tug the inventor prefers to have made of iron, or other suitable metal, covered with leather, and to hinge the one part of the tug to the other by a knuckle hinge, and secure the end by a spring latch of brass or other metal, which catches into a brass catch placed close to the buckle by which the tug is attached to the back band of the harness, having a loop or eye of metal for passing the back band through, thereby doing away with the necessity of passing the back band round the shaft. *Patent abandoned.*

102. E. W. Hughes. *Improvements in engineering and architectural structure.* Dated Jan. 14, 1862.

This consists in constructing cylinders or tubes suitable for columns or supports used in engineering and architectural structures, by forming and combining plates of wrought or malleable iron, each of which is rolled with two other projecting flanges, which are produced at angles greater than a right angle to the plane or outer surface of the plate. *Patent completed.*

103. J. Paine. *Improvements in printing and ornamenting kamptulicon when applied to fabrics.* Dated Jan. 14, 1862.

This consists in printing and ornamenting kamptulicon with waterproof colours after it has been applied to a fabric, and thereby forming a material or fabric suitable for floor-cloths, table covers, shoe stuffs, wearing apparel, and other similar purposes. The inventor also prints or ornaments kamptulicon with non-waterproof colours, and thereby adapts the material to a variety of purposes. *Patent abandoned.*

104. J. Jack. *An improvement in or application to cores for moulding or shaping metals.* Dated Jan. 14, 1862.

Here metallic or other chains are used or applied, either taking the place of the hay, straw, or other fibrous bands entirely, or being used in connection with a small quantity of the said fibrous materials. *Patent abandoned.*

105. M. Chadwick. *Improvements in machinery for folding or plaiting cloth, and for measuring the same.* Dated Jan. 14, 1862.

The object of this invention is the production of machinery for retaining the cloth at each fold in a firm position during the process of plaiting or folding, and for delivering the cloth to the machine as required; and also for regulating the machine for measuring and plaiting various widths of plaits or folds. *Patent abandoned.*

106. W. Gorse. *An improvement or improvements in machinery for manufacturing the cut nails called brads.* Dated Jan. 14, 1862.

This consists in an arrangement of parts for guiding and giving a compound motion to the strip of iron from which nails of the kind called brads are cut. The motion given to the strip consists of the ordinary swivel motion in combination with a side or lateral motion, whereby the strip is carried backwards and forwards, so as to be operated upon alternately by the bell cutters, in conjunction with the bottom or fixed cutters. *Patent completed.*

107. S. W. Marsh. *Improvements in breech-loading fire arms.* Dated Jan. 14, 1862.

This invention is not described apart from the drawings. *Patent completed.*

108. T. Harrison and J. G. Harrison. *Improvements in ploughs.* Dated Jan. 14, 1862.

This consists in adapting to ploughs a pressing wheel and plate combined for performing in one operation the ploughing of the land; and pressing the furrows so produced, so as to form a bed suitable for receiving the seed. *Patent completed.*

109. C. Hill. *Improvements in the manufacture of lubricating compounds.* Dated Jan. 14. 1862.

Here the patentee prepares a pulp or jelly by boiling down "carragea" moss, to which he adds, in certain proportions, flour, yellow soap, tallow, palm oil, lead, and a variety of other materials, according to whether he wishes to produce a thick or liquid grease. *Patent completed.*

110. J. Harris. *A semaphore target marker.* Dated Jan. 14, 1862.

This refers to an instrument for denoting where the bullet strikes the target, at whatever position or angle, and the instrument is composed of a dial with an indicator hand, worked by a winch handle, operated upon the marker; the dial and indicator are placed in such a position, and are so made as to be seen at long distances. A vane and cardinal points with signal flags can be attached when required. *Patent abandoned.*

111. J. G. Marshall. *Improvements in the machinery and processes for producing fibre from woven and other textile fabrics.* Dated Jan. 14, 1862.

The object here is to disentangle the strands of warp and weft of woven and other textile fabrics in a better manner than heretofore, and then to comb or card the strands so as to reproduce the fibre in a more advantageous form for subsequent manufacture than would result from the processes now in use for that purpose. For this purpose the patentee divides the woven or other fabric into strips in a direction diagonal or oblique to the strands of the warp and weft, so that the strands both of warp and weft may be equally acted upon when presented to a cylinder covered with card filleting or other suitable points. The strips cut or divided in this manner are placed on a travelling endless apron and are fed between feeding or holding rollers, which retain or hold them while they are operated upon by a rotating cylinder covered with card filleting or other suitable points, whereby the fibres are combed out or carded as in the usual process of treating wool, tow, and other fibres. He finds it useful to feed the strips on to the cylinder through several sets of feeding rollers, each set consisting of two or more rollers, so as to feed the material on to the cylinder very slowly. *Patent completed.*

112. E. Lord. *Improvements in or applicable to looms for weaving.* Dated Jan. 15, 1862.

This relates to the manufacture of check straps, and consists in applying vulcanised india rubber, &c., thereto, for rendering them elastic, so that, when struck by the picker or picker-stick to propel the shuttle through the shed, they will expand, and be again in the proper position for checking the momentum of the picker or picker-stick. *Patent abandoned.*

113. W. Cleland. *Improvements in treating and utilising certain materials used and products obtained in the manufacture of gas, and in apparatus connected with the said treatment.* Dated Jan. 15, 1862.

We cannot here devote space to the voluminous details of this invention. *Patent completed.*

114. T. Timmins and T. Simmons. *A combination bath.* Dated Dec. 15, 1862.

This consists in so constructing these baths that each shall combine in itself all the advantages of the hot air or Turkish bath, with the vapour, slipper, hot and cold shower bath; and this the patentees effect by constructing the body of the bath of sufficient size and capacity for general use, with a projection at the head, so that when using this bath as a hot air or vapour bath, a pillow may be placed on the projection for the head of the occupant to rest on. Some little way from the bottom they place a strong frame stretched with cane, wire, or other non-absorbent material, for the patient to recline on, and at the sides, when required, they also place frames stretched in the like manner, standing off at a little distance from the sheet-metal sides of which the bath may be composed, for protecting the user from contact from the hot metal. At the foot an air-way is constructed, and a suitable lamp or other heating apparatus for heating air, which is sent into the interior of the bath through the air-way before mentioned. The body of the bath is partially covered over from the bottom end upward, and to this a counterpoise cover is attached, with a close hinge or other joint, so as to form a lid to entirely cover up the bath, excepting at the top end, where an opening is formed for the neck of the occupant, as the body only is intended to be subjected to the effects of the hot air or vapour. *Patent completed.*

115. J. Ridsdale. *Improvements in preparing sheet lead for covering floors, stairs, and other like purposes.* Dated Jan. 15, 1862.

This consists in sinking by pressure from presses, rolls, or hand tools, designs or patterns on that surface of the sheet lead which, when laid, is to come uppermost, and in filling up such sunken designs or patterns with colour or not, according to requirement. *Patent completed.*

116. H. D. P. Cunningham. *Improvements in means for protecting screw propellers from entanglement or being fouled by ropes or other bodies; also improvements in means for closing up the screw propellers.* Dated Jan. 15, 1862.

These improvements consist in affording protection to screw propellers from being fouled or entangled by hawsers, ropes, wreckage, and other bodies, by chains and bars so arranged as to be capable of being removed or raised up out of the water when the protection is not required, in order that they may not offer impediment to the progress of the ship. *Patent completed.*

117. J. Brooke. *Improvements in the form of lubricators.* Dated Jan. 16, 1862.

Here the inventor takes a square hollow box, preferably metallic, having the inner bottom face curved conically, and having a projecting mouth and lip formed in the slide, which communicates with a discharge tube; within this cup or box he mounts a bush or bushes, which are so disposed as to rotate upon an axis always sweeping or approaching the bottom of the cup, and extending and pressing against the lip of the orifice of the discharge pipe each time as it passes during its rotation; oil or other lubricating matter is put in to the box, and motion being given to the axle upon which the brushes are mounted, these take up the oil, and on meeting the lip it is pressed out and falls down the discharge pipe upon the machinery. *Patent abandoned.*

118. J. A. Knight. *The application of a diamond cutter, and improved machinery for operating the same, for dressing millstones.* (A communication.) Dated Jan. 16, 1862.

This consists in the novel construction and arrangement of the different parts of a machine for dressing mill stones. Among the parts are a double guide-way parallel rule, with the means of operating the same, a diamond-cutting instrument with the means of guiding the same, a diamond-cutting instrument with the means of guiding, operating and steadying said instrument, two adjustable steel shields secured in a channel formed in the lower surface of the parallel rule to protect the setting of the diamond, two raised ledges of metal secured to the under surface of the double guide-way forming a channel for the parallel rule to rest upon, and a self-adjusting diamond protector. The invention is not described apart from the drawings. *Patent completed.*

119. E. H. C. Monckton. *Improvements in apparatus for obtaining and applying motive power.* Dated Jan. 16, 1862.

This consists in dispensing with boilers, and in generating steam or vapour in the most rapid manner, by the circulation in small quantities of pure or distilled water, or other fluid, air, or gas, or mercury placed in a reservoir, and pumped or forced simultaneously through one or more metallic tubes, properly supported and stayed and shaped, so as to withstand pressure, which have been heated with coal, coke, or gas &c., and then passing the steam or elastic fluid so generated through the cylinder of an engine, or other apparatus, having thereby produced motive power. The steam or elastic fluid is then passed into a condenser constructed of a series of flattened tubes or flat vessels placed in a cylinder or other receptacle, which are cooled either by a current of air being forced between them by any suitable means, thus circulating above them and then passing through the cylinder or receptacle, or else by water or a shower-bath arrangement added to a blast of air, thus combining the cooling properties of air with those of rapidly vapourised water. The steam, vapour, or gas having become condensed and reduced again to its former bulk, or thereabouts, is repassed into the original reservoir, whence it is again pumped or forced by any suitable means into circulation through the heating apparatus and engine. *Patent completed.*

120. T. Mantaule. *An improved runner fastening for umbrellas, parasols, sunshades, and other similar articles.* Dated Jan. 16, 1862.

This consists in attaching to the stick a pin, staple, or other projection, and in forming in each end of a tubular runner a curved or suitably formed slot, into which the pin or projection passes and locks itself as the umbrella or other article is either opened or closed, being forcibly held therein by the natural spring of the umbrella frame. *Patent abandoned.*

121. W. Tristram. *Certain improvements in power looms.* Dated Jan. 16, 1862.

This consists in the novel application of india rubber or other elastic spring buffer or stoppers to receive the concussion of the slay, to limit its throw, and prevent it beating up more closely sometimes than at others. *Patent abandoned.*

122. H. Wheatcroft. *Improvements in the manufacture of bonnet and cap fronts and similar fabrics.* Dated Jan. 16 1862.

This relates to that part of the manufacture of cap and bonnet fronts called the banding machinery, and more particularly to machinery for banding singles, and consists of a lead or plate mounted upon a suitable frame, the plate being corrugated or triangular on the surface so as to present two ridges, and the under part of the plate is heated with gas. On the upper surface of the triangular faces of the plate, and parallel to them, are laid two small rectangular slips, hinged so that when lying on the angular faces of the plate they form an opening, but when they are raised horizontally the opening is closed. The invention also includes arrangements for opening and closing the slips, and whereby the band is attached to the cap or bonnet front. *Patent completed.*

123. T. Myers and E. Myers. *Preventing rust on bright steel, iron, brass, or metal surfaces.* Dated Jan. 17, 1862.

The patentees, take, say 10 lbs. of gutta percha, 20 lbs. of mutton suet, 30 lbs. of beef suet, half a gallon of sweet oil, two gallons of neat's-foot oil, one gallon of oil of thyme, and half a pint of rose pink, or other suitable perfuming and colouring matter. These ingredients are gently simmered until the whole is dissolved and well mixed together; when cold, the composition is ready for use. *Patent completed.*

124. R. Dunlop. *Improved means for facilitating calculations.* Dated Jan. 17, 1862.

This relates to means for facilitating calculations, and consists in a collection of leaves or strips of paper, parchment, linen, metal sheets, or other material, which should be made up into a book containing a number of leaves, say twelve leaves for instance, and these leaves, each or some of them, divided into a number of sections or smaller leaves or strips by cutting or separating them so that the leaves may range one above the other, or otherwise range together as required. This book contains calculations in money, or it may be used for calculations on other tables. *Patent abandoned.*

125. J. M. Rowan. *Improvements in the construction of steam hammers.* Dated Jan. 17, 1862.

This invention is not described apart from the drawings. The patentee claims constructing movable cylinder steam hammers with slide piston rods, or with steam communication separate from such rods as described. *Patent completed.*

126. B. Moss. *The application of certain material or mixture of such material with clay or substances and for the manufacture therefrom of bricks, fire blocks, and so forth, applicable to the construction of iron furnaces, copper smelting furnaces, and other metallurgical operations, glass house sieges for pots and glass houses, and for the linings of furnaces, also for the manufacture of crucibles for the melting of brass and other purposes.* Dated Jan. 17, 1862.

Here the inventor by preference reduces the steatite to a powder, then moistens it with water, to which in some cases it is preferred to add a weak solution of potash, or other chemicals, thereby forming a slip or plastic substance out of which the articles to be manufactured are formed by being pressed into matrices of the required form by hydraulic or other powerful machinery to give it the required adhesion and form, after which the articles are baked or burned in the usual way. *Patent abandoned.*

128. J. C. Dickey. *An improved quartz crusher.* Dated Jan. 17, 1862.

This quartz crusher is composed of a drum having an axis projecting from each of its ends, the drum being divided at right angles to the axes into two parts, the two parts being held together by bolts and nuts. The axes of the drum are hollow, and on one of them is keyed a pulley, by which the drum may be caused to rotate; the end of one of the hollow axes is in connection with the end of a pipe coming from a hopper, in which the quartz to be crushed is placed, so that the drum is fed from this hopper with the quartz to be crushed. In the other hollow axis is fitted a conical sieve, through which the quartz as it is crushed escapes and passes away through the end of the hollow axis. Around the interior of the periphery of the drum is a ring or lining which is caused to rotate with the drum by projections on the ring entering recesses in the drum. Within the drum are three or other number of blocks or hammers of an oval section; the hammers turn eccentrically upon pins carried by the sides of the drum, and, as the drum revolves, the hammers fall over against the ring or lining, and crush the material in the drum; the action of the hammers also causes the pulverised material to escape through the sieve. *Patent abandoned.*

129. R. Romaine. *Improvements in apparatus to be used in cultivating land by steam power, and in steam boilers used for agricultural and traction purposes.* Dated Jan. 17, 1862.

This invention refers to a previous patent of the year 1859, No. 1,229, and consists in certain arrangements of parts by which the traction rope may be made to control the slack rope, the apparatus being rendered applicable to winding gear, in which the two ends of a rope are alternately wound up by two winding drums, one drum winding whilst the other allows the rope to run off. The invention also relates to an arrangement of winding apparatus, in which are employed three V-shaped grooved sheaves, geared together and placed alongside the steam-engine on vertical axes. Also, the invention consists in constructing a dead anchor to resist the draught of the implements employed in steam cultivation. Also, in improvements in the fire-box of the common horizontal tubular boiler employed for agricultural or traction purposes. *Patent completed.*

130. J. Tow. *Improvements in the construction of stoves or fire-places.* Dated Jan. 18, 1862.

The object here is the construction of stoves or fire-places for heating apartments or buildings, whereby the draught can be easily regulated and the escape of smoke into the room or apartment prevented. There is also an arrangement by which hot air may be conducted from such stoves to any part of a building. Stoves or fire-places constructed according to this invention are formed in several parts, so that they may be readily taken to pieces for examination or repair, and for facility in fixing. *Patent completed.*

131. T. Emmott and J. Travis. *Improvements in the manufacture of velvet, velveteens, and other similar piled fabrics.* Dated Jan. 18, 1862.

This relates to the manufacture of piled fabrics, the pile of which is produced by the weft threads floating over the warp threads, and the principal feature consists in the application of coarse binding weft threads to form the back of the fabric, and finer weft threads for the face; also in the application of coarse warp threads to form the back of the fabric, and finer ones to form the face. *Patent completed.*

132. T. NEWTON. *Improvements in sights for rifles.* Dated Jan. 18, 1862.

This relates, 1, to the fore-sight, and consists in making it portable and adjustable, instead of having it permanently fixed to the barrel of the piece. 2, to the back-sight, and consists in improved modes of filling up the space between the sliding or elevating bar and the bottom of the holder. *Patent completed.*

133. E. DAVIES. *Improvements in apparatus for gauging and cutting soap.* Dated Jan. 18, 1862.

Here the inventor employs two plates of metal or wood, forming two sides of a box, placed at the required distance apart and used as a gauge. Between the said sides of the box a wire or knife is placed horizontally, so that, when the said box is moved along the surface of the soap, it gauges and cuts at the same time. *Patent abandoned.*

134. W. HELME. *A newly-invented fire-lighter.* Dated Jan 18, 1862.

This fire-lighter the inventor constructs from the waste blocks of wood out of which bobbins, spools, &c., are cut. The cylinders for forming the bobbins, spools, &c., are cut so that the remaining portion of the block shall be connected together, thus forming a skeleton. This he either dips into molten resin or other inflammable matter, or fills the holes with resin, pitch, or other material. *Patent abandoned.*

135. J. J. STEVENS. *Improvements in point indicators for railways.* Dated Jan. 18, 1862.

This invention was described and illustrated at page 51 of our last number. *Patent completed.*

136. W. TICE. *Improvements in gas regulators and other apparatus in which movable spindles are employed.* Dated Jan. 18, 1862.

This consists, 1, in soaking such flexible diaphragms, of whatever material they may be composed, in glycerine, or other like substance, and afterwards coating them with a mixture of treacle or glue, or other saccharine and animal matter reduced to a proper consistency, for preserving the flexibility and filling up the pores of such flexible diaphragms; 2, in all gas regulators and such like instruments in which various descriptions of metal spindles are used, travelling in or through some description of metal, the inventor either makes such spindles with glass, porcelain, or other like material, and he also inserts in the cover, or in such part of the instrument in which the spindle should work, a tube of glass, porcelain, &c.; and he also makes the valves of, or covers them with, glass, porcelain, or other like materials; or he coats the valves and valve seals with an alloy of silver or other non-corrosive substance. *Patent abandoned.*

137. S. DREYFOUS. *An improved throstle spinning frame.* (A communication.) Dated Jan. 18, 1862.

This invention is not described apart from the drawings. *Patent completed.*

138. W. S. WINANS. *Improvements in the manner of mounting and apparatus for manœuvring cannon or ordnance on ships or vessels of war and floating batteries.* Dated Jan. 18, 1862.

The patentee claims, 1, mounting cannon or ordnance, and their carriages and platforms, on board ships, &c., so that they may be raised and lowered at pleasure by steam or other motive power for the purposes set forth; 2, making hatchways or openings in the upper decks of ships, &c., through which the cannon or ordnance may be raised from and lowered to an under deck for the purposes set forth; 3, adapting to such hatchways or openings covers which are to be worked or moved by the agency of steam or other power. *Patent completed.*

139. T. ROBERTS and J. DALE. *Improvements in the manufacture of gunpowder.* Dated Jan. 18, 1862.

This consists in a method of making gunpowder, whereby the patentees are enabled to use nitrate of soda instead of or in combination with nitrate of potash. This they effect by adding thereto a substance which will effloresce, so as to correct the tendency of the other material or materials to become moist. Of these substances they name, for example, the anhydrous sulphate of soda and magnesia. *Patent completed.*

140. W. S. MAPPIN. *A new or improved lock.* Dated Jan. 20, 1862.

This invention is not described apart from the drawings. *Patent completed.*

141. A. BARBAT. *Some improvements in the manufacture of hats, bonnets, and other like articles.* Dated Jan. 20, 1862.

This relates chiefly to the manufacture of fancy hats, and consists in the employment of a fabric having its warp and weft of horse-hair &c. only, or having either its warp or weft of silk, cotton, &c., combined with fabrics composed of other materials. *Patent completed.*

142. T. HOLT. *Improvements in folding iron chairs and chair bedsteads.* Dated Jan. 20, 1862.

This has reference chiefly to the mode of sustaining the chair-back, and is carried out as follows:— Near the forward upper angle of the parallelogram or other figure described by the bars forming the arms, the inventor joints a diagonal piece, and on the horizontal part of the arms he cuts notches to receive a pin or other catch of the diagonal piece; this diagonal piece fixes the arms in position, and thereby sustains the chair-back. Any person can readily alter the position or incline of the back at pleasure, by simply moving the diagonal catches from one set of notches to another. *Patent abandoned.*

143. T. W. JOBLING. *Improvements in the adaptation of locomotive engines to traction or haulage in mines.* Dated Jan. 20, 1862.

The patentee claims, 1, feeding or supplying the furnaces and boilers of locomotive engines with fuel and water previously heated; 2, condensing the exhaust steam and products of combustion by causing them to pass into and through a tank of cold water before discharging them into the atmosphere. *Patent completed.*

144. W. BOALER. *Certain improvements in the method of sizing paper yarns and woven fabrics, and in machinery or apparatus connected therewith.* (A communication.) Dated Jan. 20, 1862.

This consists in the use of steam in combination with pure starch or other sizing material directly upon the paper, yarn, or cloth in the sizing vessel or receptacle, or upon the surface of the sizing roller or its equivalent, as described. *Patent completed.*

145. A. LAMB. *Improvements in life-boats.* Dated Jan. 20, 1862.

The patentees construct life-boats according to this invention with longitudinal water-tight compartments or air chambers formed on each side of the boat, and extending from stem to stern, or between the bow and stern compartments, and carried up to the gunwale; these are combined with bow and stern water-tight compartments extending from side to side of the boat. These bow and stern compartments should be only of such a height from the bottom as to leave a space below the top side of the gunwale, the space thus left being made available for seats, when not designed to be otherwise employed. Or, in certain cases, these compartments may at the sides extend above the line of gunwale, leaving a flat space or recess sufficiently below the line of gunwale to enable the weight of persons seated in such recess to be kept as low as possible. For carrying a gun forward, the compartment at the bows is extended in length sufficiently far aft to provide a suitable bearing for the gun-carriage, and to enable the gun to work clear of the mast. *Patent completed.*

146. J. BIRD. *An improved crank axle applicable to cranks of any description whatsoever, wherein the wear is mainly on one side thereof.* Dated Jan. 20, 1862.

This consists in forging the axles between each pair of collars, where collars are used, and where collars are not used at each extremity of the axle, of an oval form on the side where the wear will mainly be, and of a semicircular form on the other half thereof; each collar has a recess forged or otherwise formed in it to receive the snugs which are cast on the ends, and which form part of a piece of iron or other metal, which is shaped in such wise that, when one of such castings is laid on the axles formed as above described, the said casting will form the axle round, the casting being secured to the axle by a screw passed through the snugs and into the axle outside the collars, where they are used, whereby when the casting is worn nearly through, by the pressure of the bearing upon it, it can be readily replaced by another casting. The same method may be applied to axles which are fixed having the bearings revolving, or having the bearings fixed or movable. *Patent completed.*

147. E. C. NICHOLSON. *Improvements in the preparation of colours suitable for dyeing and printing.* Dated Jan. 20, 1862.

Here the patentee takes red dye, such as is made from aniline or its homologue, and without the admixture of either aniline or its homologue, heats it carefully to a temperature, by preference, between 390° and 420° Fahr. The substance quickly assumes the appearance of a dark semi-solid mass, the red dye being transformed into a dark substance with evolution of ammonia. The mass he prefers afterwards to extract with acetic acid, using a quantity of acid about equal in weight to the amount of red dye treated, and this acid he dilutes with enough alcohol to make a dye of convenient commercial strength. The solution obtained is of a deep violet or purple colour, and may be used directly for dyeing purposes. *Patent completed.*

148. J. W. AGNEW. *An adjusting last.* (A communication.) Dated Jan. 20, 1862.

This is carried into effect as follows:—To the usual or any form of last are affixed toe plates, or thin sheets of malleable iron, steel, brass, or other hard metal, of about one-eighth of an inch in thickness, and of about 3 inches in length, which toe plates are fastened to the last by a screw, working through a slot in the same, of about an inch in length, into a metal nut inserted in the toe of the last, which screw and nut hold the toe plate securely to the last. In order to lengthen the last, the screw is loosened, and the toe-plate pushed forward to the size required, when the screw is made fast again, and so on. *Patent abandoned.*

149. R. O. DOREMUS and B. L. BUDD. *Making cartridges.* Dated Jan. 20, 1862.

The patentees claim, first, forming the ordinary granulated gunpowder of commerce into shapes suitable for use as cartridges, by compacting the same within moulds by pressure, so applied as to condense the said powder into those shapes, substantially as described. Second, giving to the cartridge the principle of acceleration by forming it in strata of different rates of combustibility, substantially as described. Third, combining the ball or other projectile directly with the powder, to form a fixed charge, substantially as described. *Patent completed.*

150. J. STENHOUSE. *Improvements in the protection of metallic surfaces, and in rendering certain substances less pervious to air and moisture.* Dated Jan. 21, 1862.

This relates to the use of the substance called paraffin, either in a solid state or dissolved in any of the usual solvents, such as highly-rectified coal tar or petroleum, naphtha, or bisulphuret of carbon, for protecting metallic substances, and rendering certain substances less pervious to air and moisture. The metallic surfaces which the patentee proposes protecting are, gold and silver leaf, brass, tin, and tin-foil, copper, bronze powder, mosaic and Dutch gold, and the various kinds of gilding and gilded articles. The substances which he proposes rendering less pervious to air and moisture are, felt, flocks, woollen yarn, cotton yarn, flax yarn, manufactured skins and furs, artificial flowers and leaves. The method of applying the paraffin to metallic surfaces consists in coating them therewith; the mode of applying paraffin to the substances before named consists in coating or impregnating them therewith. *Patent completed.*

151. J. A. KNIGHT. *Improvements in the permanent way of railways.* (A communication.) Dated Jan. 21, 1862.

The object of this invention is to connect the cross ties, sleepers, or pedestals and chairs and rails in such a way that they will constitute a complete and well-secured system, without the intervention of any bolts or keys or other fastenings, and it consists in fitting the cross ties and pedestals together with a socket or lock joint, and in combining them with chairs that conform to the section of the rails and hold them securely without the usual taper keys or wedges. To prevent the injury incident to concussion upon a perfectly rigid support, the patentee interposes india rubber or other elastic material between the parts, so that it is easy of access and permits of the adjustment of the track without disturbing the pedestals or the ballasting of the roadway. *Patent completed.*

152. J. F. TOURRIER. *The diffusion of heat in houses by means of hot air without extra fire.* Dated Jan. 21, 1862.

Here a grate such as is generally used is provided with an air chamber or tank of iron, screwed at the back or sides of the grate, which chamber or chambers will from their position derive great heat from the fire, the heated air contained in the above chambers being communicated by pipes. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated May 3, 1862.

1307. H. Juhel, Bordeaux, France, ironmaster. An improvement in wheels. (A communication.)

1316. G. Neall, Islington, Middlesex. Improved apparatus for obtaining and applying motive power, especially applicable to propelling carriages on common roads.

Dated May 8, 1862.

1377. A. Bearne, 24 Union Street, Torquay, Devon, boot maker. Improvements in the construction of boots, shoes, and goloshes, rendering them elastic to pressure.

Dated May 19, 1862.

1517. A. V. Newton, 66 Chancery Lane, Middlesex, mechanical draughtsman. Improved machinery for splitting leather. (A communication.)

Dated June 14, 1862.

1767. J. Lancelott, Clifton Terrace, Birmingham, jeweller. Improvements in the manufacture of ornamental chains from sheet metal.

Dated June 21, 1862.

1836. A. F. Maigron, 46 Rue Grande Marengo, Marseilles, France, mechanician. Improvements in machinery or apparatus for the manufacture of tow or oakum, and for winding off, carding, and spinning all kinds of fibrous fabrics.

Dated June 24, 1862.

1855. J. Johnston, Paisley, Renfrew, North Britain, hat manufacturer. Improvements in hats.

Dated June 25, 1862.

1868. J. Whitham, Perseverance Ironworks, Leeds, engineer. Improvements in the apparatus used in working oil and other hydraulic presses.

Dated June 26, 1862.

1873. E. T. Hughes, patent agent, 123 Chancery Lane. Improvements in regulating or moderating the movement of the keys of piano-fortes. (A communication.)

Dated June 28, 1862.

1897. G. H. Hulskamp, Troy, New York, pianoforte maker. Improvements in pianofortes.

Dated June 30, 1862.

1910. W. F. Murray, Glasgow, Lanarkshire, N.B., potter. Improvements in the manufacture of stoneware bottles, and in apparatus connected therewith.

1912. W. Easton, Oakinellgate, Gateshead-on-Tyne, and G. Donkin, Bill Quay, Gateshead-on-Tyne, Durham. Improvements in lears or annealing chambers and apparatus used in annealing glass.

Dated July 3, 1862.

1937. T. Turner, gun manufacturer, Fisher Street, Birmingham, and W. Taylor, engineer, Aston New Town. Certain improvements in single and double breech-loading fire-arms.

1939. W. A. Gilbee, South Street, Finsbury, London. An improved manufacture of blue colouring matter. (A communication.)

Dated July 7, 1862.

1956. C. Wessely, 22 Canterbury Place, Lambeth Road, Surrey. Improvements in carriages.

Dated July 8, 1862.

1961. J. H. Johnson, 47 Lincoln's Inn Fields, Middlesex, 166 Buchanan Street, Glasgow, North Britain, gentleman. Improvements in wet gas meters. (A communication.)

1963. J. Brown, Middleton, Lancashire, machinist. An improved motion for actuating the doffers of carding engines for carding cotton and other fibrous substances.

1965. C. Slatford, manufacturer. Improvements in trimmings, tufts, and other articles for ornamental and decorative purposes.

1966. J. Rigby, Suffolk Street, Dublin, Ireland, gun maker. Improvements in breech-loading guns, and in extracting cartridges from such guns, and also in wind sights for fire arms.

1969. H. Wethered, Bristol, colliery proprietor. Improvements in the construction of handles, latches, or fastenings for doors, gates, and windows.

Dated July 9, 1862.

1970. W. L. Wiggington, 4 Clifton Cottages, Hammersmith, Middlesex. An improved method of, and apparatus for, curing smoky chimneys.

1973. A. Gilbey, Oxford Street, London, wine merchant. Improvements in apparatus for washing and cleansing bottles.

1975. J. Rhodes, Morley, Leeds, machine maker. Improvements in rag machines. (A communication.)

1977. H. Eschwege, 14 Mincing Lane, London. Improvements in purifying wood and other vinegar.

1978. G. T. Bousfield, Loughborough Park, Brixton, Surrey. Improvements in washing machines. (A communication.)

1979. E. S. Hindley, Bourton, Dorsetshire. Improvements in apparatus used when circulating hot water for warming dwelling-houses and other places, which apparatus may be used for cooling and condensing.

1981. S. V. Evers, 80 Lower Thames Street, London. Improvements in the preparation of beverages. (Partly a communication.)

Dated July 10, 1862.

1983. W. F. Reynolds, Commercial Road, Middlesex. An improved watch pendant.

1985. H. Kellogg, New Haven, Connecticut, America. Improvements in breech-loading fire arms and cartridges therefor.

1986. J. Mander, Birmingham, manufacturer. Improvements in crochet needles and crochet needle holders.

1987. A. Bonnell, Hethpool Street, Maida Hill, Middlesex. Improvements in churns. (A communication.)

1989. E. J. Biddle, New York, engineer. The use of petroleum or coal oil as fuel, and also for the machinery and apparatus to be employed for this purpose.

1991. J. Leeming, North Holme Mills, Bradford, Yorkshire. Improvements in jacquard or index machines.

1992. D. Steele, Bunhill Row, Finsbury, Middlesex. Improvements in the method of flushing or distributing the water in pans or basins applicable to waterclosets, urinals, wash-hand basins or other purposes.

1993. T. Farra, Manchester, salesman. Improvements in wearing apparel, called skirts or petticoats and frocks.

1994. J. H. Johnson, 47 Lincoln's Inn Fields, Middlesex, gentleman. Improvements in braiding machines. (A communication.)

Dated July 11, 1862.

1995. J. R. Hill, engineer, 7 Duke Street, Adelphi, London. An improved governor for the engines of steam vessels.

1996. M. Cornall, Manchester, Lancashire, doubler, and E. Griffiths, yarn agent. Improvements in doubling, twisting, and reeling threads and yarns of cotton and other fibrous materials.

1997. J. Waithman, Manchester, flax spinner. Improvements in machinery or apparatus for carding flax, tow, or other fibrous materials.

1999. J. Orr, Glasgow, manager. Improvements in weaving piled fabrics, and in the machinery or apparatus connected therewith.

2000. J. Miller, Lambeth, Surrey, gentleman. Improvements in apparatus for steering ships and other vessels.

2001. W. Bliss, Chipping Norton, Oxfordshire, woollen manufacturer. Improvements in heating ores, and in generating steam, and also in the apparatus employed therein. (A communication.)

Dated July 12, 1862.

2002. C. E. Green, 13 Blanford Street, Portman Square, Middlesex, and J. Green, Windermere Cottage, Winchmore Hill, Edmonton. Improvements in breech-loading fire-arms.

2003. J. P. Lees and J. Beard, Ashton-under-Lyne, Lancashire, machine makers. Certain improvements in carding engines.

2005. J. Hunt, Queen's Mill, Preston, Lancashire. Improvements in the process of sizing and drying yarns or threads, and in the apparatus employed in such process.

2007. T. Hill, Hampton House, Great Warley, Essex, brewer. Improvements in the arrangements employed for the protection of markers at rifle-butts, and in the means employed in indicating the score and position of the shot and wiping out the shot mark.

2008. E. T. Hughes, Chancery Lane, London. An improved system of winding or rolling silk thread on moulds or bobbins and placing them in suitable boxes. (A communication.)

2009. J. H. Johnson, 47 Lincoln's Inn Fields, Middlesex, gentleman. Improvements in machinery or apparatus for washing ores and minerals. (A communication.)

2010. W. E. Gedge, 11 Wellington Street, Strand, Middlesex, patent agent. Improvements in the manufacture of hats. (A communication.)

2011. P. Plassan, Tours, France, doctor. An improved orthopœdic apparatus for straightening the human frame.

2013. H. Barber, spring knife cutler, 60 Thomas Street, and H. de Garrs, brass and wood turner, 34 Pomond Street, Ecclesall Bierlow, Sheffield. Improvements in rolling iron, steel, and other metals for cutlery tools and other purposes.

2014. The Hon. W. E. Cochrane, Osnaburgh Terrace, Regent's Park, Middlesex. Improvements in railway fastenings.

Dated July 14, 1862.

2015. E. Taylor, 167 Regent Street, London. Improvements in the manufacture of buttons.

2016. G. Lowry, Salford, Lancashire, machinist. Improvements in machinery for carding and cleaning cotton and other fibrous materials.

2017. W. E. Gedge, 11 Wellington Street, Strand, Middlesex. An improved portable or stationary steam lift and force pump. (A communication.)

2019. C. Crossley and J. W. Crossley, Halifax, Yorkshire. Improvements in means or apparatus employed in washing and finishing textile fabrics.

2020. S. Partridge, Darlaston, Staffordshire, surgeon. Improvements in railway signals.

2021. P. Sanderson and R. Sanderson, Galashiels, Selkirk, North Britain, manufacturers. Improvements in the manufacture of woven fabrics, and in the machinery or apparatus employed therein.

2022. W. G. May, Glasgow, cabinet maker. Improvements in apparatus for extending tables.

2023. P. A. L. Canonicat, 50 Rue des Petits Pères, Marseilles, France, civil engineer. Improvements in filtering water, and in apparatus employed therein.

2024. G. Faweus, North Shields, Northumberland, shipbuilder. Improvements in building boats.

2025. F. M. Parkes, Plumstead, Kent, gentleman. Improvements in the manufacture of gas for lighting and heating, and in apparatus employed in the said manufacture.

2027. R. Ridley, Morlui, near Leeds, Yorkshire, and J. G. Jones, 4 Cambridge Villas, Battersea, Surrey. Improvements in machinery and apparatus for ventilating mines and other places.

Dated July 15, 1862.

2028. A. Leslie, Turriff, Aberdeenshire, North Britain, farmer. Improvements in apparatus for applying steam or other motive power to cultivate the soil and to actuate wheeled carriages.

2030. J. Green, Newtown, St. Martin, Worcestershire, agriculturist. Improvements in the method and means of producing signals, and in the application of the same, particularly to steam ploughs and cultivators.

2033. W. Dickens, Salford, Lancashire, machine maker, and J. Hewitt, Manchester, machinist. Improvements in self-acting and hand mules employed in spinning cotton and other fibrous materials.

2034. C. E. Crawley, 17 Gracechurch Street, London, and F. Foster, 7 Ashley Crescent, City Road, Middlesex. Improvements in safety or miners' lamps.

Dated July 16, 1862.

2036. B. Johnson, Chester, engineer, and E. H. Taylor, Coed Talon, Mold, Flint, engineer. Improvements in rope wheels, cages, and tanks used for mines, collieries, and other similar purposes.

2037. G. T. Selby, Smethwick, Staffordshire, tube manufacturer. Improvements in apparatus for superheating in tubes and tubular articles and in machinery for the manufacture thereof.

2038. L. R. Bodmer, 2 Thavies Inn, Holborn, London. Improvements in apparatus for winding up watches and other time keepers. (A communication.)

2039. W. Henson, Nottingham, engineer, and W. W. Clay, Sneinton, Nottinghamshire, machinist. Improvements in knitting machinery, and in apparatus connected therewith.

2040. A. V. Newton, 66 Chancery Lane, Middlesex, mechanical draughtsman. An improvement in sewing machines. (A communication.)

2041. C. Sanderson, Sheffield, Yorkshire, steel manufacturer. Improvements in the manufacture of crinoline or crinoline steel.

Dated July 17, 1862.

2046. J. G. Harkness, Birkenhead, Cheshire, storekeeper. An improved safety handle for winches, cranes, and other like machines.

2048. T. B. Daft, 2 Queen Square, Westminster. Improvements in the manufacture of mats and other surfaces, where vulcanised india rubber is employed.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

2052. O. F. Morrill, Massachusetts, America. A certain new and useful apparatus for generating heat for culinary or various other purposes. *Dated July* 18, 1862.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

693. G. Calvert. Castors.

703. G. H. Birkbeck. Trusses or bandages. (A communication.)

726. J. T. and T. Pendlebury. Lubricator.

749. J. Banks. Electro-magnetic telegraph printing apparatus.

760. R. A. Brooman. Barytes and barytic products. (A communication.)

763. R. Hadfield and J. Shipman. Hardening and tempering wire and crinoline steel.

767. R. A. Brooman. Printing and painting upon glass and ceramic wares, and upon metallic and mineral substances. (A communication.)

768. R. A. Brooman. Producing copies of guipure, lace, embroidery, and other like articles. (A communication.)

770. R. A. Brooman. Drawing in and paying out chain cables. (A communication.)

777. E. Smith. Apparatus for cutting stone, wood, and other material.

778. E. Field. Apparatus for regulating the flow of gaseous and other fluids.

780. W. Clark. Manufacture of soap. (A communication.)

785. J. Newall. Supplying gas to railway carriages, stations, steamboats, and other vessels.

788. J. Humphrys. Steam engines.

789. B. H. Mathew. Fire-arms and cartridges.

790. W. Phelps and W. R. Lymbery. Improved woven fabric, and improvements in machinery for manufacturing the same.

795. T. Fontenay. Smoke-consuming furnaces.

797. E. Lord. Preparing cotton and other fibrous substances.

798. J. Davis. Wind musical instruments.

801. J. H. Tuck. Flexible valves.

802. J. G. Jennings. Biscuits.

817. J. Stewart. Cards for jacquard weaving. (A communication.)

824. T. Guibal. Ventilation of mines and furnaces.

834. W. J. Taylor. Colouring Portland cement.

842. A. V. Newton. Separating the fibres of wood, flax, hemp, and other vegetable substances, and extracting the colouring matter therefrom. (A communication.)

847. F. Tolhausen. Cigar-tubes or apparatus for holding and smoking cigars. (A communication.)

876. C. H. Townsend, J. Young, and J Hankins. Removing and preventing incrustation in steam boilers.

889. R. Young. Cleaning, separating, washing, and drying grain.

916. H. W. Whitehead and G. Bray. Carding wool and other fibrous substances.

919. H. J. Madge. Coating iron sheets or plates.

956. T Silver. Governors.

1049. W. Clark. Leathern accoutrements. (A communication.)

1108. W. E. Newton. Manufacture of cannon and other ordnance. (A communication.)

1127. C. D. Abel. Certain alloys containing cadmium. (A communication.)

1162. C. Callebaut. Sewing machines.

1192. W. Haggett. Engines and carriages for railways.

1196. J. Winsborrow. Wet gas meters.

1245. G. R. Samson. Valves or cylinders for wind musical instruments.

1251. W. E. Newton. Picking, burring, and cleaning wool. (A communication.)

1419. J. B. Pope. Lowering and loading coals, minerals, or other substances.

1465. J. P. Jouvin. Preserving iron-plated and other vessels and metallic articles from oxidation.

1786. A. Crestadoro. Obtaining and applying motive power from rarefied air.

1844. H. Ponsonby. Top-sail sheet bits or bolts.

1884. E. Hunt and H. D. Pochin. Condensing apparatus.

1891. A. A. Croll. Treatment of ammoniacal liquor of gas works.

1900. C. Callebaut. Sewing machines.

1912. W. Easton and G. Donkin. Lears or annealing chambers.

1926. J. James. Welding railway crossings.

1934. J. Webster. Gas for illumination.

2001. W. Bliss. Heating ores and generating steam. (A communication.)

2040. A. V. Newton. Sewing machines. (A communication.)

2052. O. F. Morrill. Generating heat.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed July 25, 1862.

209. W. Orr.
229. J. H. Brierley.
236. J B. Harby.
243. G. Phillips, sen. and G. Phillips, jun.
278. T. Cook.
282. L. Hill.
290. G. Manwaring.
297. J. Webster.
300. W. E. Taylor.
308. J. B. Payne.
400. J. H. Johnson.
425. J. Combe.
470. W. Ashton.
498. W. E. Newton.
856. W. E. Gedge.
1185. J. H. Johnson.
1258. A. V. Newton.
1350. J. H. Johnson.
1352. J. H. Johnson.
1592. W. Palmer.

Sealed July 29, 1862.

249. W. Davies.
257. H. Schatten.
262. P. Scheurweghs and A. J. A. H. De Boisserolle.
264. E. H. C. Monckton.
269. W. Smith.
280. F. Riesbeck and W. Becker.
284. C. W. Lancaster.
288. W. Clark.
293. J. L. Norton.
299. D. Gallafent.
311. A. C. Bamlett.
320. J. Tonkin.
328. W. Clark.
330. W. H. Bartholomew.
339. M. A. F. Mennons.
356. W. Wood.
378. M. A. F. Mennons.
484. M. A. F. Mennons.
606. T. Hack.
994. J. Whitehouse.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

1761. P. A. Viette.
1744. J. Scoffern.
1747. E. Hunt and H. D. Pochin.
1765. J. Wood.
97. C. A. Girard.

PATENTS ON WHICH THE SEVENTH YEAR'S STAMP DUTY HAS BEEN PAID.

1691. W. Weallens.
1695. C. Schiele.
1800. V. Delperdange.
1850. A. V. Newton.
1732. J. Hanson.

Note.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, AUGUST 8, 1862.

EXHIBITION, 1862.

Marine Engineering.

In resuming our observations on the Marine Engine display in the International Exhibition, and the mode in which the duties of the jurors have been performed, it will be necessary continually to bear in mind the instructions issued by the Royal Commissioners for the guidance of the jurors in the distribution of their awards, or we shall run the chance of doing the latter some injustice, which we should much regret, remembering that their duties could under no circumstances be otherwise than onerous. With respect to the construction of the juries we have a word to say.

In our view, no one should have been engaged on any of the juries who was either an exhibitor in his respective class, or even in any way engaged or interested in the trade of those whose products he was called upon to examine and adjudicate upon. It might have been urged that very great difficulty would have been found in obtaining a sufficient number of jurors wholly disengaged from trade and yet competent to discuss purely practical questions. We admit the difficulty, but feel quite assured it could have been overcome, especially as in most cases the number of the jurors was unnecessarily large. The Royal Commissioners would also, doubtless, throw much of the blame of deciding upon unfit judges on the exhibitors themselves, inasmuch as the former state that the names selected were mostly those proposed by the latter. But let us ask whether any one person exhibiting marine engines, for instance, desired to have the merits of his productions determined by manufacturers of rival plans. The idea is monstrous. Class 8, in which the marine engines appear, included also many other things; and it is quite possible that a *majority* of exhibitors in this class (General Machinery) might propose the names of persons as jurors who were well known for their skill as mechanical men, but not rivals in their own special trades. We venture, however, to say, without fear of contradiction, that no exhibitor proposed the name of a rival manufacturer in his own special department. The result of the Commissioners' mode of selection, therefore, although at first sight apparently perfectly fair, practically was most unfair; for by it A's productions were judged by jurors selected by B, C, and D, such jurors being unobjectionable as judges of the latter's manufactures, but a rival manufacturer of A, and not therefore competent as a judge of his work.

It was not enough, in order to reconcile exhibitors to the Royal Commissioners' selection, to exclude jurors who were exhibitors from those entitled to receive prizes; this was, of course, necessary, but wholly insufficient to satisfy exhibitors that justice was done. Indeed, as it has turned out, this withholding of prizes from jurors was a matter of very little moment, for the number of medals given has been so large that the fact of the jurors who are exhibitors receiving prizes would hardly have been looked upon with even suspicion, most of the jurors who are exhibitors being at the head of their respective trades, and thus, in all probability, as deserving of a prize as many others.

To begin with the medals awarded to the exhibitors of marine engines in the United Kingdom section, and in taking them alphabetically, we note the name of Humphreys & Tennant, of Deptford. In this case a medal is well and properly bestowed, but not altogether on the grounds assigned by the jurors. The engines are good, undoubtedly, as regards "simplicity," "accessibility of all parts," and "good workmanship," but they are not "compact;" for the space occupied by engines of this class, with ordinary but short connecting rods, is, if the condensers be placed so as to balance the cylinders — i. e., nearly the same distance from the shaft — anything but compact. The jurors might as well, indeed more reasonably, have assigned "originality of general design" as one of the reasons of their award. The link motion is good and original, and we think the best in use; but in other respects there is nothing special in the engines. The jurors pass over entirely the model of the Mooltan's engines, perhaps because it was not catalogued, but possibly because these engines were the first of the kind made. These engines are not only novel in their arrangement, that is as vertical screw engines (for the use of two cylinders, one behind the other, was suggested and patented in 1855) but present the most recent example of what may be done in improving marine engines as regards saving of fuel. Thus, notwithstanding Mr. Humphreys's claim to this arrangement of cylinders for screw engines is contested, yet, as the matter stands, the model was well worthy of separate notice, much credit being due to the manufacturer for the trouble he has been at in carrying out the plan practically, although the notion of double cylinders for screw engines, placed end to end, was, as we have said, patented seven years ago.

Of the award to Messrs. Laird of a medal, we have nothing to say, except that it is well "simplicity" was not one of the grounds of commendation. The medal is, however, fairly given.

Messrs. Maudslay obtain a prize for "general excellence" of their engines, "also of the collection of working models." Now, this is too bad. We don't mean to say that Messrs. Maudslay are not deserving of a medal for their engines, which, of course, are good working machines, although the valves being at the top of the cylinders makes them somewhat complicated, and less desirable, in our view, than other forms; but we object to a good collection of models, merely as a collection of models, getting a medal. The jurors have evidently here been delighted with seeing well-made models in motion and ship-shape order; but there is nothing in all this for which to give a medal. If any notice had been taken of the models at all, it should have been for the one showing Mr. Sell's arrangement of three cylinders, the same as fitted to the Government screw vessel Octavio, and the medal should have been awarded to the designer, as has been done in other cases. We do not altogether like the three-cylinder arrangement, but there is enough in the practical working out of the details to warrant special notice being taken of it. To award a medal for "general excellence" in a number of models, is simply nonsense. Why should not Ravenhill & Salkend have a medal on the same grounds? their models are just as well made as Maudslay's, but then they were *not at work*. Ravenhill's were the first to bring out the double piston-rod arrangement for screw engines; and of their engines on this plan may be predicated, not only "general excellence," but "compactness," "simplicity," "practical "success," and a good many other things which should fully have entitled them to a medal, and would have obtained one if their models had been accompanied by a full-grown engine of say 600 or 800 horse-power. The jurors "honourably mention" the models of oscillating engines exhibited by this firm. We assume they mean both the inclined and ordinary vertical cylinders, for no distinction is made. The ordinary oscillating engines of Messrs. Ravenhill are amongst the very finest that have ever been made, and might well have merited some special notice. Would not they have obtained it, if they had been exhibited on a scale of a pair of 400 horse-power engines?

To the award of a medal to Messrs. Morrison we have nothing to say. The engines are "compact" and "simple;" and although we cannot believe vertical cylinders for driving screws will be long in use, there they are when wanted, with the various parts well put together and arranged.

Messrs. Napier, of Glasgow, obtain a medal for the engines of the Persia, which are well known to have worked satisfactorily, but we can scarcely reconcile ourselves to this firm deserving a medal for their engines, unless it be for the determination they have shown, in face of all opposition, to adhere to the old type of engine, with its multitude of parts, in preference to those of more modern construction. With a handful of medals, however, undistributed, the jurors could not well help sticking one behind Messrs. Napier's drawings, especially as these are not "opposition" engines, Messrs. Napier having them all to themselves.

The engines of Messrs. Rennie have deservedly obtained a medal for "originality," the arrangement of two trunk cylinders and two trunk air-pumps, being compact and working satisfactorily. It is a great pity, however, that the double cylinder horizontal engine this firm constructed, on Mr. E. E. Allen's patent, expressly for the Exhibition, could not be completed in time. The arrangement will be found very badly illustrated in Part IV. of the Official Illustrated Catalogue, in which it is described as capable of exerting an indicated horse-power (when fitted with surface condensers, superheaters, and feed-water heaters) by the consumption of about 2 lbs. of coal. These engines—a pair of 8's—may be seen, we believe, at Messrs. Rennie's factory by those interested, and photographs already are, or shortly will be, exhibited on their engines in the Exhibition. It would be satisfactory to know what the jury would have done with reference to these new engines, had they been exhibited; the advantageous working of the principle, viz., that of double expansion, being fully proved in the case of the Mooltan's engines, of which, however, as we have said, the jury took no notice.

Of the award made to Tod & M'Gregor's engines, we would observe the same as in respect to Messrs. Morrison's. For an inverted single expansive cylinder engine, the arrangement is good and easily repaired.

Randolph & Elder exhibit drawings of their double expansive screw engines, as arranged for the Government screw Constance; and logs of their double expansive paddle engines of which several pairs have been for some time working satisfactorily on *half the ordinary consumption of fuel*. From the drawings representing engines actually made, and the logs of engines actually worked for some years, we should have felt certain that the jurors would

have awarded this firm a medal; but they do not get even honourable mention. How is this? Supposing their names are not in the catalogue, this is no reason, as the drawings and logs are in the building, and were so, we feel assured, before June 15. Perhaps these gentlemen do not care for a medal; but if they do, they may at least console themselves with the public judgment that they ought to have had one. Although there are some arrangements in their screw engines which we do not like, their paddle engines have never been beaten, and can hardly be beaten; at any rate they are, taking economy of fuel into account, the best engines at present made.

Mr. E. E. Allen's models occupy a somewhat retired position near the entrance, but against the wall. This exhibitor was late in getting his models in; and this, together with the omission of them from the catalogue, prevented the jury from examining them until after the awards were made, at which several of them have expressed their regret.

One of the models represents a horizontal screw engine, with small and large cylinders end to end, and corresponds with the engines built by Messrs. Rennie, before referred to, and of which we understand two pairs are being made by Messrs. Day & Co., of Southampton, as well as a pair of 500-horse power by Humphreys & Tennant for the Poonah. These last engines, however, have a trunk for attaching the connecting rods to— an arrangement also shown in Allen's patent of 1855; and the second model has a new arrangement for screw or paddle engines, patented the early part of this year in the name of E. E. Allen & John Stewart. In this case the cylinder is divided into two parts, and has a double-pistoned trunk working in it. The steam from the boiler acts round the trunk and thence expands on the whole area of the pistons at each end of the cylinder. As we shall probably illustrate this patent when specified, we shall not attempt further to describe it here, but would merely add that the model representing this and the other double-cylinder arrangement for driving screw propellers might fairly, for their novelty, and it may almost be said success of one of the forms, have received a medal from the hands of the jurors. Of the few other honourable mentions and of the foreign exhibitors, we shall speak in a concluding article next week.

SEWING MACHINES IN THE INTERNATIONAL EXHIBITION.

No. II.

In estimating the value of a sewing machine, the great point is, to get a mechanical contrivance to do the work of a needlewoman or tailor quicker than the fingers of a needlewoman or tailor can do it; as neatly and as strong; and to adapt the machine to all the manipulations of the sempstress and tailor, or even the cordwainer. The public generally is not conversant with the technical names given to stitches and seams. Perhaps it has heard of hemming and herring-boning, of gussets and button-holes. It has a complete work brought before it, in the masculine or feminine department of the household, and it approves or disapproves *ad captandum*; but the public knows no more in general of the technicalities of a garment than Jacob Omnium knows of the architectural technicalities of his suburban villa, or the veterinarian terms applied to his cob.

Now, it has been the aim of inventors and improvers in the sewing machine to do all that human fingers can accomplish with the common needle and thread. They intend that the machine should embroider, work plain-stitch, hem a handkerchief, do the gatherings of a skirt, ornament the uppers of my lady's slippers, or do the sterner duty of securing the soles and other parts of my lord's boots and shoes. They intend that it should accomplish all in needlework, from the maid's rough work in the kitchen, to the young lady's more ambitious efforts in the drawing-room. That these ends have been accomplished to a great extent, may be seen by anyone who has an interest in the matter, through paying a visit to the very clever operators on these handy little machines in the International Exhibition.

The Howe sewing machine is entitled to priority of mention among those exhibited in the American Court. His is the basis of all successful machines. Since the date of his patent in 1846, various improvements have added considerably to its utility, without at all affecting its principle. That principle was the stitch formed of two threads by means of an eye-pointed needle, carrying a thread for one side of the goods, and a shuttle carrying also a thread for the other; the needle passes the thread in a loop through the cloth, while the shuttle passes its thread through the loop, when, by the combined action of the feed-motion, and a fresh passing of the shuttle through the loop, the stitches are drawn tight and interlocked within the body of the fabric, forming a tight seam, the stitch of which cannot be unravelled. The feed-motion, which is a combined patent of Howe, Wheeler & Wilson, Singer, and Grover & Baker, is a very ingenious contrivance for propelling the work by means of a serrated plate, by which the material can be turned at will to any desired curvature without interfering with the progressive motion of the fabric through the machine. This was suggested by a basterplate which Howe had invented, but which the four-motion feed has now superseded. It will thus be seen that the essential characteristics of Howe's invention may be thus enumerated :—

1st. A mechanism for making stitches, or interlocking of thread, combined with an apparatus for making tension on the thread, and drawing up and securing each stitch when formed.

2nd. An apparatus consisting of two surfaces, between which the material to be sewed is contained, and which support it against the thrust and retraction of the needle, and in such a position as to permit the stitches to be drawn tight.

3rd. An automatic, intermittently-acting, feeding apparatus, which causes the material to pass with a regular movement between the holding surfaces in the intervals between the punctures of the needle with an unerring precision and uniformity of effect, impossible to obtain by hand.

These three essential properties were never in use in any sewing machine prior to Howe's, and no machine has been subsequently made without them, in a more or less modified degree.

But Howe has improved marvellously and effectively, even upon these, by the invention of a cylinder machine. This is as great an advance upon his original invention as that was upon hand sewing; it is the introduction of an entirely new principle in sewing by machinery. All shuttle sewing machines make their stitch by the needle entering the material and remaining there until the shuttle passes and takes up the loop. By the cylinder machine, the needle pierces the material to be sewn, carrying its loop with it in its downward course, and leaves it within the material, then returns, when the shuttle starts forward, takes the loop and tightens the upper thread; the needle-arm is then lifted considerably, and the shuttle-thread by that means tightened. It will be seen that the stitch is thus made when the needle is *out* of the material, and, as a consequence, very close sewing, closer even than by hand, can be made. The cylinder machine carries the finest and coarsest needle, and will sew from one thickness of kid to the stoutest harness leather, with ease and facility; it also admits of anything being sewn upon it which cannot be laid flat upon the sewing plate of an ordinary machine—such as a narrow sleeve or the leg of a boot. The award of a prize medal to Howe's sewing machine will, we think, be acquiesced in by all its competitors.

Wheeler & Wilson's machine is very remarkable on account of the novelty of its construction. Here we have still the double stitch; but the "lock" is accomplished by means of a rotating hook instead of a shuttle. The underfeeding bobbin differs also from those used in other machines. This bobbin is about the diameter and thickness of a florin; but between the two surfaces there is a deep groove, containing the requisite supply of thread. The bobbin is placed within the rotating hook, and winds off according to the demands of the machine. The rotating hook itself, larger in diameter than the bobbin, is the segment of a circle—a complete circle almost, but interrupted in its periphery by a kind of gash. The effective segment of the gash has a pointed end, which catches into the loop made by the needle, drags it round about three-quarters of its circuit, when the thread is released and pulled tight through touching a rest. The hooked wheel revolves again to catch a loop, and again to make a close stitch. But in these successive revolutions it not only catches itself into the down-loop from the needle, but inserts the thread from the bobbin it carries. There is a small apparatus on the surface of the machine for spooling the thread. The tension is so regulated that the upper and under threads are used together equally, so that there are no loose stitches, and the seam cannot be drawn into puckers.

The annexed diagrams will tend, perhaps, to make the mode in which this machine

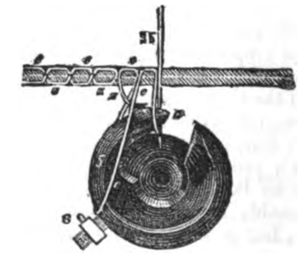

Fig. 1.

operates plain to the reader. The stitch is formed by the combined action of an eye-pointed needle, 35 (fig. 1), carrying the upper thread, *e*, a rotating hook, 5, and a double convex metallic spool carrying the lower thread. It will be observed that the needle having descended, as it rises the line of thread upon its right is slightly looped. The point, *a*, of the rotating hook, 5, reaches the needle at this instant, passes close to its right side, and enters the loop of thread. As it further revolves, it enlarges this loop and carries it forward. As the loop slips from the point of the hook, and is drawn up, it will be found to

enclose the lower thread, and interlock with it. The loop would slip from the hook when it had made little more than one-half of a revolution, and as it is drawn up by the hook in enlarging the next loop, it is necessary to hold it until the hook shall have completed the revolution and entered the next loop. For this office, the loop-check, 36, is employed. It consists of a small brush, or an equivalent, held in slight contact with the periphery of the hook as it rotates, and thus holds the loop as in fig. 1, and prevents its slipping until the hook has completed its revolution, and enters the next loop at the needle as seen in fig. 2.

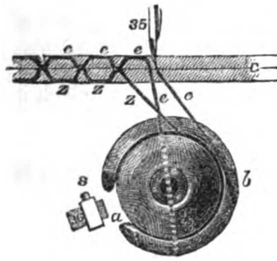

Fig. 2.

The chamfered portion of the hook then reaches this check and relieves the loop, which is then drawn up, as seen in the same figure; when this is so worn as not to check the loop, it should be adjusted. The Wheeler & Wilson machine is a pretty-looking, pleasant-working piece of mechanism, and at the present moment stands high in point of popularity.

The sewing machine of Wilcox & Gibbs is a single thread chain stitch, against which some people have a prejudice, from its liability to ravel, or "run out." It is certainly possible, by undoing the finishing loop, to draw the whole out, but ordinary wear will not do this: and its beauty of stitch and great rapidity of operation render it useful for many kinds of domestic work. That it has held its own against the competition of shuttle-stitch and lock-stitch, is a proof of some goodness in it, which is not to be despised. There is a curious history connected with this particular invention, as curious as that relating to the history of fluxions. In the latter case it has been matter of doubt whether Sir Isaac Newton or Huygens was the discoverer. It is said that the letter of the great English philosopher, announcing to the great Dutch philosopher his mathematical discovery, crossed the letter of the Dutchman to the Englishman, communicating a similar result of intellectual grasp and effort. So it was with James Gibbs. He had never heard of a sewing machine. He had never heard of Duncan's, invented fifty years before. He was a homely, plodding farmer in the mountains of Virginia, who took it into his head that he could dispense with "sewing days"—an American "institution" not always to the liking of the master of the house, who does not care for an invasion of needles and thimbles upon appointed occasions to put the family wardrobe to rights. A "sewing-day," we take it, must be as terrible an infliction to the American husband as a "washing day" is to the English one. James Gibbs, without knowing what Morey and Howe had attempted, or were about, employed his active brains in inventing a sewing machine, and succeeded. The character of the stitch, and the method of forming it, bear some resemblance to those in the machines of Chas. Morey, but the apparatus is superior in construction and well adapted for a variety of domestic purposes. The great peculiarity in the mechanism is a "spur looper," which catches the slack down-loop, retains it, and by its peculiar conformation holds the next down-loop distended so as to be caught again at the next revolution of the spur. By this arrangement, there is no chance of a stitch being dropped, and the seam is as even and tight as can be desired. "The shape of the needle and manner of adjusting it are secured by patent to James Wilcox, and the machine has the exclusive use of a convenient, self-acting, and noiseless stop, by which a reverse motion of the wheels is prevented, and also of a guard to protect the dress of the operator from the rubbing of the balance wheel. The apparatus for catching and looping the thread as it is passed through by the needle consists of two arms making together a cross at the end of a horizontal axis. As this revolves close to the needle under the cloth plate, one of these arms, shaped like a hook, and rapidly enlarging toward its base, catches the thread and spreads the loop, which is then brought against the axis, and next slips upon the other arm, which gives the loop a twist and holds it. At the same time the needle goes up and comes down again through the cloth, carrying its thread through the loop already formed, when it is caught by the hook, and the first loop being released is drawn tight by the pulling of the hook in spreading the second. *The twist given to the thread in forming the loop has a material effect in strengthening the hold of the thread in the cloth, and thus producing a very strong and durable seam.* Its strength and little liability to rip may be readily seen by cutting a narrow strip across the seam of a piece of cotton thus sewed, and comparing it with a similar piece sewed by hand. On attempting to pull or rip the pieces apart, *it will be found that the former thus tested is the stronger of the two.* The tendency to ravel, hitherto the objectionable feature of machines of this class, is in this obviated by the drawing of the end of the thread through the preceding loop by the hook at the last stitch, and thus fastening it whenever it is broken by design or accident. If, however, this loop should be loosened and the end of the thread withdrawn, and then pulled, the whole seam may be ravelled like knitting work; but this can only occur when an end is first loosened in this manner, and no such result is likely to take place in ordinary wear. The needle, being short and straight, runs with perfect exactness and certainty across seams, and even over several abruptly increasing thicknesses of cloth."

These machines have become the family instruments for sewing in a great many households in England as well as in America, and their great simplicity and ease of operation are strong commendations in their favour.

The machine of Mr. J. M. Singer has little in it to be described beyond the ordinary shuttle machine. It is manufactured under licence from Howe, whose machine it most resembles. There are some peculiarities about it as regards the spring tension between the spool and the needle, and the check-regulating wire. This machine has been largely used in manufactories—such as those for slops, and soldiers' clothes. It has given employment to many hands in this direction. The firm has manufactured, from first to last, about 60,000 machines, 8,000 of which have been sold in England. Their manufactory in New York gives employment to 800 persons.

We have in a former number noticed Mr. Bigelow's boot-sewing machine, and, were it not a "sewing machine" in principle, there would be no need to mention it again. Sew, however, it does, and that the thickest leather with as much facility as the other machines sew cloth or muslin. We do not know whether the shoemaker and tailor crafts be in danger by these machines; but looking at them from our own point of view, we are led to believe that their general use will be to exempt a large number of the present or coming generation from the sedentary occupations of the stool and the shop-board.

The American Court is, undoubtedly, the great centre of interest for sewing machines, and there may be some truth in the remark of a lady visitor to the Exhibition—herself, however, an American—that if America had sent nothing else to the grand show of the industry and ingenuity of nations than sewing machines, these in themselves would have been a noble contribution. It is only those who have looked into the frame-work and mechanism of these, who are able to appreciate the ingenuity which was requisite to produce them, and, seeing them in operation, can value their utility.

FORTIFICATIONS AND GUNS.

Three pamphlets have just issued from the press, which, in their bearings and tendency, have so near a relationship to each other that we do not hesitate to discuss their merits in the same article. The first of these is entitled, "Sir Morton Peto, and the Defence Commission;" the second, "The Armstrong Gun compared with Rifled Cast-iron Service Guns (unstrengthened), on Mr. Bashley Britten's System;" and the third, "A Few Words on the Construction of Ordnance, by an Outsider." It is not necessary for us to reiterate here our own opinions upon the general questions of the best means of protecting our shores and of the kind of artillery which should be employed afloat and ashore for the purposes of defence; those opinions are too well known to require recapitulation. We have, however, a love of fair play, and a desire that the public—who have to bear the expense of all the experiments and schemes, enquiries and commissions, made or instituted by the Government in respect to fortifications and guns—should hear all sides of the question.

In the first-named pamphlet, an attempt is made by its anonymous author to prove that Sir Morton Peto, in his recent written and spoken onslaughts upon the Defence Commission, was actuated by unworthy motives, and guilty of unfair conduct towards the members of that commission. His principal crime consists, according to this authority, in the publication of certain "Observations on the Report of the Defence Commissioners, with an Analysis of the Evidence," and wherein are evinced palpable misrepresentations, and convenient suppressions of the truth. These are, undoubtedly, heavy and serious charges to make against a public man, and especially one whose moral qualifications are rated so highly as those of Sir Morton Peto. It must be admitted, nevertheless, that a considerable amount of colour is given to these charges by the knight-errant who represents the Commissioners. It is too often the case that rival pamphleteers, in the desire to upset each other's arguments, indulge in personalities which only weaken their own, and betray infirmities of temper, rather than evolve sound axioms. To some extent, this is true, both of Sir M. Peto and of the "Unknown" who has now entered the lists against him. The writer of "Sir Morton Peto and the Defence Commission" traces the history and the doings of the commission from the period of its issue,

under the advice of Lord Herbert, in the month of August, 1859, to its latest achievement in the shape of a report presented to Parliament very recently. He also furnishes brief biographical notices of the ten members who now comprise it, and, from their antecedents, draws inferences of their fitness for the posts they hold. Extracts are also given of the reports of the Commission in the years 1860 and 1861, with a view to support their consistency, which was "battered" at in the "Observations" of Sir Morton.

With this preliminary matter, though interesting enough in itself, it is not our present purpose to deal. It will be more profitable to our readers, we trust, to come to the gravamen of the charges laid at the door of the hon. member for Finsbury, and to see by what evidence they are sought to be justified. The plaintiff, or counsel, rather, quotes from the "Observations" of Sir Morton the following paragraph :—"In all the opinions they have "expressed as to the relative cost of forts and "ships, the report of the Commissioners is as "completely at variance with the evidence of "their witnesses, as upon the other points of "their investigation." To this the reply is, that "the fact is not so; but, even if it had "been so, that circumstance in itself would "not necessarily have been any impeachment "of the judgment or conduct of the Commis- "sioners." The conclusions of a commission, further observes Sir Morton, "can only be of "value so far as they may reflect the evidence "of the witnesses before them. In the present "instance, the Defence Commissioners obtained "the evidence of several officers of the naval "and military services, whose professional "knowledge and position entitle their opinions "to great consideration. The evidence of "these officers will show Parliament and the "public, the little authority which the Com- "missioners have for their conclusions, and "the absolute manner in which they have "ignored the evidence." These are strong words, undoubtedly, but the justification of the Commissioners is to be found, so thinks their defender, in the fact that "each of the "gentlemen comprising the Commission was, "at least, as competent to give a judgment on "the questions submitted to them as any of "the witnesses who appeared before them. " * * * The Commissioners were not "bound to call any witnesses before them at "all, on matters of which they themselves "were quite competent to judge; and if they "did call them, they were not bound to sur- "render their own judgment to the opinions "of those whom they consulted." These and other arguments are adduced in support of the independent action of a Royal Commission, and its right to frame its report in accordance with the sentiments of its own members. We cannot but coincide with Sir Morton's opponent on the point at issue: and, thinking thus, must admit that much of the indignation of the member for Finsbury has been idly expended.

The reasons which induce Sir Morton Peto to abstain from giving evidence before the Commission, when invited to do so, are obscure, and, to a certain extent, unsatisfactory; but we can hardly suppose that the theory of his refusal is to be found, as suggested, in the consideration that "it is much easier to write "an address to a constituency on a subject "that they do not understand, than to support "propositions in the presence of persons who "are sufficiently well acquainted with the "subject to test the value of an opinion." Passing forward to Sir Morton's "Analysis of "the Evidence," and taking for granted the allegations made against it, it is difficult to come to any other conclusion than that its writer was most anxious to sustain his attack upon the Commissioners, and not too scrupulous about the means. We cannot, of course, reproduce all the statements made in the pamphlet before us tending to justify this opinion, but, as an example, we adduce one in reference to the evidence given before the Commission by Captain Hewlett. Sir Morton Peto states in his "Analysis," that this witness "appeared to "be as little in favour of the forts as the other "witnesses." In order to make good this assertion, he then quotes Captain Hewlett's replies to questions 247 and 249, but omits that to question 248, which question and its answer run thus:—"If a certain form of iron- "plated ships were appropriated for the de- "fence of Spithead and Portsmouth, do you "consider that the Spithead forts would aid "the ships to a certain extent?"—"I think "there is no doubt that they would be a valu- "able assistance to ships taking refuge there; "if our force were superior to the attacking "force, they would be valuable in affording "refuge, and enabling you to make sorties "from under the forts to attack the enemy." To use the mildest form of expression, there does appear an abundance of ingeniousness on the part of the hon. member in omitting to mention this admission of Captain Hewlett. We have no love for the Spithead forts, but must plead guilty to a weakness in favour of having out "the truth, the whole truth, and "nothing but the truth."

Without, however, expending further comment upon this well-written pamphlet, we must say that the public will look for a rejoinder to it from Sir Morton, or they will be apt to think that, in his desire to demolish the fortifications off Portsmouth, he has allowed his assumption of the advocacy of floating defences to cloud his sense of moral rectitude.

The second pamphlet referred to above, is one which demands a larger share of attention than we can at present devote to it. It is calmly written, dispassionately argumentative, and thoroughly practical. Its title, indeed, very truthfully illustrates its character; and facts and tabular formulæ, based on experiments, go to demonstrate the soundness of the author's views. It will be a simple act of justice on the part of those who still adhere to the notion that Armstrong guns are the *ne plus ultra* of our artillery armament, to obtain and read Mr. Britten's little pamphlet, which is published by Mitchell, 39 Charing Cross, and which is replete with sound information. It may be that we shall next week analyse it, and give examples of some of its averments.

The "Few Words on the Construction of "Ordnance," by Mr. Charles Gubbins—whose name was honourably mentioned during the Indian mutiny—are well worth listening to; and, although the author is modest enough to call himself "An Outsider," he has exhibited strong claims to notice from those who are "insiders" in the knowledge of gunnery. Mr. Gubbins lays claim to much of the honour which has been accorded to Sir William Armstrong, and states that the processes of manufacture formerly adopted, at the suggestion of that very fortunate gentleman, "have been found insufficient to "bear the charges of powder at present ex- "perimented with, and that he is falling back "on methods identical with those suggested "by Mr. Gubbins in 1854, and which were "then placed at the disposition of the Govern- "ment." Under pressure of unquestionable testimony, such as that of the author of "A "Few Words," and the still heavier pressure of repeated failures of the Armstrong gun, it will require something more than the offhand and unsustained assertions of Sir Cornewall Lewis to bolster up the weapon about which so much controversy has been waged, and, alas! upon which so much money has been expended.

We cordially recommend to the scientific public the third pamphlet of the series; and we feel assured that out of that chaos which the authorities of the nation have managed to create, order will presently emerge. The works we have now referred to are suggestive and valuable, and, although the first-named may appear to be of a somewhat personal character, yet they all tend to the dispersion of official mists, and to the consequent placing the question of Fortifications and Guns in a clearer light than that in which it is now seen.

THE METROPOLITAN MAIN DRAINAGE WORKS.

(From *The Times*.)

The great main drainage scheme of London is a work of such magnitude as no city in the world but this would require, and certainly a work of such cost as very few cities in the world but this could afford to pay for. There is something almost grand in the idea of a single city consenting to pay nearly 4,000,000*l.* sterling for subterranean drains, which never have been and never can be seen, and of which our descendants will almost doubt the necessity, from the radical nature of the cure they will bring about in the health of the metropolis. That the change it will effect on the cleanliness of the city, and, therefore, on the health of the inhabitants, will be most important, our readers will readily believe; but, in order that they may fully understand what is the improvement, it will be necessary to say a few words about the old system which the new is to supersede. It used to be an old saying, that London was the best drained city in the world. There are plenty of drains, no doubt—in fact, the subterranean web of drains and sewers which burrows beneath London is said to be more than 2,000 miles in length. There is, however, a dark side to this picture, and that dark side, as our readers can easily guess, is the Thames. It is in vain that we speak of our drainage, and point to the hundreds of miles of sewers and drains which have been added to London within the last ten or fifteen years. Every new drain, in fact, only increased the evils of a system which at last became unendurable, and which, but for the means which have been taken to abolish it, must have made a plague-spot of the whole metropolis. The only matter for astonishment is that our costly and incessant efforts to poison the air and water have not been thus punished long before this. It is the knowledge that in the ordinary course of events a visitation of this kind could not be much longer averted, that has led to the great main drainage scheme being undertaken.

It is of the general features of this great plan that we now propose to give our readers an outline. The subject is, we own, a dirty one, and scarcely adapted for the literature of the dog-days; but after inhaling dirt and drinking dirt for so many many years, we may well afford to read about it and to look statistically into that foulest of all our great sewers, the river Thames. Until the adoption of the present scheme, the object of all London drainage was to make the Thames the great main sewer of the metropolis, an object which we shall see was realised to the fullest possible extent. All the sewers in London on both sides of the river run due north and south, discharging themselves into the Thames within a length of some five or six miles. At the very first glance this arrangement seems bad enough, though it is infinitely worse when we come to examine how it was arranged to work. On both sides of the river the banks are very little above high-water mark, while the average level of the ground immediately behind them is much below it; half

Lambeth, Bermondsey, and Rotherhithe being 6 ft. below high-water level. Of course, when this is the level of the ground, the sewers are much lower still, and their outlets so completely tide-locked that it is only at dead low water that they can empty themselves at all. Thus, for nearly eighteen hours out of the twenty-four the sewage on both sides of London used to be, and is still to an immense extent, pent up, giving off its miasma into every street and house. As we have said, it could only escape at dead low water, when the returning tide immediately churned it *up* the river, keeping all its abominable "flotsam and jetsam" above bridge till the tide ebbed out, finding 200,000 or 300,000 gallons of filth to be operated upon in a similar manner on its return. This was the arrangement twelve years ago, and is almost entirely so still; but, even bad as this was, it was capable of being made worse; and worse accordingly it was made. In 1849 most of the houses in London had cesspools attached to them, and a very large proportion were without any drains at all. The alarming nature of this evil showed itself slowly but surely in the Bills of Mortality, and the then Commissioners of Sewers, who were feebly battling with the evils of the drainage system, set to work to mitigate the cesspool danger by drainage, making the Thames, as usual, the general receptacle. From that time to the present some 700 or 800 miles of new drains have been made, and all cesspools made to drain at once into the river. By this "improved" drainage some 200,000 additional gallons of sewage were daily added to the Thames at low water, containing no less than 300 tons of "organic matter," which in this case is the scientific term for filth. Nor was the Thames the only sufferer. Wherever a stream could be found, no matter how clear its waters, or how beneficial its course, drains were at once made into it. Hackney Brook, once well known to anglers as one of the clearest and prettiest of streams that wound from the north of London into the river Lea, was made to vie with the Thames in filth and stench; and even the Serpentine was brought into requisition, and the Ranelagh sewer (one of the largest in London) daily discharged itself into that much-prized piece of ornamental water. The Thames, however, as the largest claimant, always got the preference of dirt, and the great mass of corruption which has flowed into it year after year has at last made it the largest and dirtiest open sewer in Europe. The result, as a matter of course, has been that in the summer months the stench from the river has occasionally been intolerable. In 1857 great quantities of lime and chloride of lime were put in daily; in 1858 the same expedient had to be resorted to again; and in 1859 the dose had to be increased to 110 tons of lime and 12 tons of chloride of lime, costing some 1,500*l.* per week. Even in a pecuniary point of view, however, this was not the only evil of the system. The Thames in this hot weather runs short of water, and when there is no rain the collections of refuse in the sewers have to be flushed into the river by artificial means. This flushing alone during summer costs 20,000*l.* a-year to get the poison into the Thames, where 20,000*l.* more is generally required to keep it from breeding a plague. The tide in summer carries off little or nothing. A marked object was set afloat in the river and watched, with a view of ascertaining this fact, and for three weeks it went backwards and forwards between Vauxhall and London Bridges, without going much farther either way. During the same period, of course, the sewage of the Thames, increased by its daily contribution, goes backwards and forwards likewise under the summer sun, and yet people profess to wonder why it smells so dreadfully. The magnitude and importance of this evil have long been known, and Mr. Bazalgette, the chief engineer to the Board of Works, fought long and assiduously to have the plan improved, and, strongly aided by public opinion, his fight has been successful. His main drainage scheme is nearly completed. In less than two years more it will be entirely completed, the Thames purified, and London effectually drained.

As may easily be imagined, it is impossible in an article like the present to give more than an outline of this great plan, which may best be briefly described as consisting of three gigantic main tunnels or sewers on each side of the river. These completely divide underground London, from west to east, and cutting all existing sewers at right angles intercept their flow to the Thames, and carry every gallon of London sewage under certain conditions into the river on the north side below Barking, and on the south to near Erith. These main drains are called the High, Middle, and Low Level sewers, according to the height of the localities which each respectively drains. The High Level on the north side is about eight miles in length, and runs from Hampstead to Bow, being at its rise only 4 ft. 6 in. in diameter, and thence increasing in circumference, as the waters of the sewers it intercepts require a wider course, to 5 ft., 6 ft., 7 ft., 10 ft. 6 in., 11 ft. 6 in., and at its termination, near Lea river, to 12 ft. 6 in. in diameter. This drain is entirely finished and in full work. Its *minimum* fall is 2 ft. in the mile, its *maximum* at the beginning nearly 50 ft. a mile. It is laid at a depth of from 20 to 26 ft. below the ground, and drains an area of fourteen square miles. The Middle Level, as being lower in the valley on the slope of which London is built, is laid at a greater depth, varying from 30 to 36 feet, and even more below the surface. This is nearly complete, and extends from Kensal Green to Bow. The Low Level will extend from Cremorne to Abbey Mills, on the marshes near Stratford; but as the city portion of this will pass through the Thames Embankment, we shall have occasion to refer to it hereafter. At Bow the Low Level waters will be raised by powerful engines at a pumping station to the junction of the High and Middle Level ducts, thence descending by their own gravity through three tunnels to the main reservoir and final outfall below Barking. These three tunnels are each 9 ft. 6 in. in diameter and nearly four miles long. Great engineering difficulties existed in the construction of these main arteries, as from the height at which they all meet, it was necessary to take them above the level of the marshes leading to Barking. For a mile and a half the embankment which encloses the three tunnels is carried on brick arches, the piers going 18 ft. below the surface, and being based on solid concrete. Apparently this ground had not been disturbed for very many centuries. In the course of the excavations Roman and early British pottery was found, with skulls of an almost totally different type from the skulls of the present day, with quaint weapons, flint spear and arrow heads, rough knives, and horse accoutrements in iron. In the marshes at Barking the reservoir for the reception of the sewage of the north side is formed. This reservoir is a mile and a half long by 100 ft. wide, and 21 ft. deep. It is made of this great length in proportion to width to allow of its being roofed with brick arches, which are again covered with earth to a considerable thickness, so that not the slightest smell or escape of miasma can take place. This reservoir is capable of containing more than three times the amount of sewage which can enter it while the pipes which communicate from the bottom of the reservoir to the bed of the river remain closed. In fact, the whole scheme of the main drainage has been carried out on the principle of making all the works large enough to meet the demands of future generations for almost the next two centuries to come. Thus, when all is complete, the works will not only be large enough to take off all London's sewage now, but its sewage when London is double its present size.

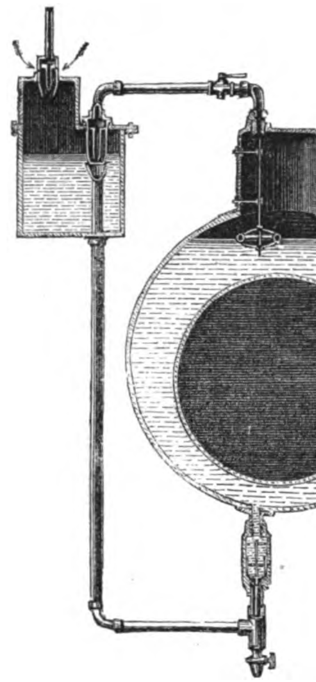
While the sewage is in the reservoir we have spoken of, it will be completely deodorised by an admixture of lime. When the tide is at its height the sluices which pass from the bottom of the reservoir far out into the bed of the river will be opened, and the whole allowed to flow away. It takes two hours to thus empty the reservoir, by which time the tide will be flowing down strongly, and will carry its very last gallon a distance of 13 miles below Barking, which, being itself 13 miles below London, will place the contents of the sewers, every 12 hours, 26 or more miles distant from the metropolis. Thus, instead of letting loose the rankest of this great city's abominations in the very midst of London, and leaving it to stagnate, or, still worse, to be agitated backwards and forwords in a small body of water, it will all be carried away a distance of 13 miles, then deodorised, then suffered to escape into a body of water more than a hundred times greater than that into which it now crawls, and thus, disinfected and diluted so as to be without either taste or smell, swept still farther down the stream, till every trace of it is lost. Many competent persons, however, are of opinion that the sewage of London possesses considerable value as liquid manure, and ought not to be thus wasted; but without at all discussing this question, on which there are many discordant opinions, we may say that arrangements are about being entered into between the Board of Works and a company which proposes to bring the question to a practical solution, and to apply the sewage as manure, for a certain time and under certain conditions. This attempt to utilise the sewage will be made on a large scale, and according to the best plans, so that, one way or other, the question as to its value will be set at rest for ever.

On the south side of the Thames the three great sewer arteries are constructed on similar plans. The High Level commences at Dulwich, and runs to Deptford Creek; the Middle Level begins at Clapham, and ends at the same terminus; and the Low Level will be from Putney to Deptford. At this point is to be a pumping station (now nearly finished), which, like that on the north side, will raise the water from the south Low Level to the channel of the High Level, whence both streams will flow of their own gravitation through a tunnel 10 feet 6 inches in diameter to Crossness Point, in the Erith Marshes. One part of this tunnel, passing under Woolwich, is a mile and a half long, without a single break, and carried at a depth of 80 feet from the surface. At the outfall will be another pumping station, to lift the water to the reservoir. The southern reservoir is only 5 acres in extent; that on the north is 14. In the reservoir it will be deodorised, and discharged in a similar way to that we have already described. The pumping stations will each consist of an engine-house, containing ten boilers, calculated to work up to 500-horse power nominal. This power working through eight pumps of 7 feet diameter and 4 feet stroke, will daily raise 19,000,000 cubic feet of sewage from 19 feet below low water to the level of the outfall, but, in case of necessity, the pumps can raise 25,000,000 cubic feet per day. Any of the main sewers can be disconnected if necessary from the others by means of sluice gates, and the chimneys of the pumping stations themselves are used to draw off and consume the foul air in the sewers. The total length of the three rows of intercepting sewers, the course of which we have sketched on each side of the river, will be 50 miles, and before all the works are completed, 800,000 cubic yards of concrete will be consumed, upwards of 300,000,000 of bricks, and 4,000,000 cubic yards of earthwork.

There are many other points of special interest connected with this gigantic scheme, but into which we have no space to enter now. We must reserve to another occasion these further details, especially those of great interest connected with the Thames Embankment.

The *Mining Gazette* (Houghton, Lake Superior) states that Wm. Bull has made an important improvement in stamping machinery at the Copper Falls Mill. The improvement consists in expediting the flow of stamped sand from the mortar, as soon as it is sufficiently pulverised for washing, thereby increasing the working capacity of the stampers to about one-third more than at present. This is accomplished by a different and peculiar construction of the mortar, increasing its area, without increasing its bulk, and permitting the rock to be fed in on two sides, instead of one, as in those now in use, insuring a more regular supply. It is stated that one set of such stampers will crush as much rock in one day as two sets of the old stampers.

OLDING'S APPARATUS FOR FEEDING BOILERS.



A PATENT has just been obtained by Mr. H. J. Olding, engineer, of Smith Square, Westminster, for an invention of "Improvements in the mode of and apparatus for feeding steam boilers; also in apparatus for supplying fluids for other purposes, and in apparatus for raising fluids," as illustrated in the above engraving.

In feeding boilers the apparatus is arranged in such manner that the fluid is fed or supplied, intending to act on the law of equilibrium of fluids, that is to say, in seeking to find its level, the apparatus is self-acting or self-regulating, so that the decrease of water in the boiler opens the passage for the feed thereinto. The invention consists of a chamber or vessel, which communicates with the boiler by a pipe so formed as to proceed in a downward direction to a level lower than the boiler, and then come upward till it enters the boiler at a convenient part. The chamber also communicates with the steam chest or upper part of the boiler by an equilibrium pipe, and it also communicates with the tank or other source of supply of water. The passage through the feed and equilibrium pipes is controlled by valves arranged as shown. When the water in the boiler sinks below a certain determined level, the valve in the equilibrium pipe opens, and steam passes through it to the chamber, the water in which, in seeking to find its level, flows into the boiler through the feed pipe, and continues so to flow until the level is again attained in the boiler, whereupon the valves in the equilibrium and feed pipes close, and the feed is stopped. The equilibrium pipe valve consists of a plate or disc, which is capable of moving up and down or to and fro (suitably guided), and is attached to a ring, annular disc, or float, floating on the surface of the water in the boiler, so that when the water is low, the stem is depressed and moves the plate down or away with it, and opens the pipe, and when the water rises the stem and plate rise with it, so as to close the pipe. The valve in the feed pipe is also movable, being a plate attached to a stem (suitably guided) and capable of moving up and down, or to and from its seat. To this stem another plate of broader surface is attached, working against an angular bend or projection in or on a spring. When the smaller plate or valve proper is moved away from its seat so as to open, the water impinges against the broader plate, which, when carried thereby over the angle, performs the rest of its travel suddenly.

These valves, instead of being jointed on to their seats, move bodily away from or wholly off them; to open the pipes their line of motion to and from their seats is in a reciprocating-wise direction, or in a right line in the longitudinal direction of their stems.

Air is admitted into the chamber, so as to accompany the feed water, by a hollow conical valve or a conical pipe or chamber forming a valve raised and depressed with the raising and depressing of the water below it; air and water are admitted into the boiler, in such proportions as to supply sufficient oxygen and water, to prevent the generation of explosive hydrogen gas.

THE MANCHESTER ASSOCIATION FOR THE PREVENTION OF STEAM-BOILER EXPLOSIONS.

CHIEF ENGINEER'S MONTHLY REPORT.

AT the last ordinary Monthly Meeting of the Executive Committee of this Association, held at the Offices, 41 Corporation Street, Manchester, on Wednesday, July 30, 1862, William Fairbairn, Esq., C.E., F.R.S., in the chair, Mr. L. E. Fletcher, chief engineer, presented his Monthly Report, of which the following is an abstract: —

"During the last month there have been examined 323 engines and 563 boilers. Of the latter, 2 have been examined specially, 1 internally, 95 thoroughly, and 465 externally, in which the following defects have been found: — Fracture, 16 (2 dangerous); corrosion, 46 (8 dangerous); safety-valves out of order, 11 (1 dangerous); water gauges ditto, 19 (4 dangerous); pressure gauges ditto, 14; feed apparatus ditto, 11; blow-off cocks ditto, 28 (1 dangerous); fusible plugs ditto, 6; furnaces out of shape, 10 (3 dangerous); blistered plates, 7. Total, 168 (19 dangerous). Boilers without glass water gauges, 12; without pressure gauges, 2; without blow-off cocks, 50; without back pressure valves, 98.

"Three explosions occurring, during the past month, to boilers not under the inspection of this Association, have come to my knowledge. One of these took place in Manchester, the other in the neighbourhoood of Newcastle, and the third in London, while all three were attended with fatal consequences. The plates of the first are reported as having been found, on subsequent investigation, so reduced by corrosion, as not to have exceeded the thickness of a sheet of paper; while it is worthy of remark, with regard to the second, that its explosion had seriously damaged another boiler alongside of it, which, however, fortunately happened at the time to be out of work, or, from the injuries it received, it must have exploded in turn. This is frequently found to be the case, and the fact is of interest, as affording an indication of the variety of forces developed by explosion, which, as has been previously pointed out, evidently cannot be summed merely in that of disruption and the reaction consequent on unbalanced pressure.

"In addition to the above, however, it becomes my duty to report the occurrence of an explosion to one of the boilers belonging to a member of this Association, and which, it is to be regretted, was attended with loss of life to the fireman.

"This is the third fatal explosion which has happened to any of the boilers under the inspection of this Association since its establishment, nearly eight years ago, to which should be added three cases of collapse of furnace flues, not attended with any serious consequences, and which arose in two instances, if not in all three, from shortness of water. During this period, 656 dangerous defects have been pointed out in the boilers under inspection, from which serious injury might have arisen in each case; while, upon limited inquiry only, it has been found that no less than 202 fatal explosions have occurred in that time to boilers not under the inspection of this Association, which have been attended with the loss of 438 lives, in addition to serious injury to 476 persons, and considerable damage to property.

"The explosion last referred to occurred to one of a pair of ordinary cylindrical double-flued boilers, working side by side and connected together. Both boilers were set upon mid-feathers, and were of precisely similar construction and dimensions, the length of each being 34 feet, the diameter of the shells 7 feet, of the flues 2 feet 7½ inches, and the thickness of plates ⅜ths of an inch throughout, with the exception of the flat ends, which were $\frac{9}{16}$ths of an inch. The fittings consisted in each case of a glass water gauge; a back pressure and feed stop-valve combined; a blow-out valve, of mushroom construction, opening against the pressure in the boiler; and a lever safety valve, loaded with a single weight to a pressure of 35lbs. per square inch; in addition to a steam pressure gauge common to both boilers as long as both junction valves were open, but not otherwise.

"The explosion was occasioned by a rent in the shell, which took place directly through the line of rivets, at one of the longitudinal seams in the second ring of plates from the front of the boiler, the seam being on the right hand side, three feet from the centre or 'keel' line at the bottom. The construction of this seam was such that the edge of the outer plate was uppermost.

"The cause of the rent was thinning of the plates at this seam by external corrosion, through which it had become reduced to about $\frac{1}{16}$th of an inch in thickness. The corrosion extended throughout the length of the seam, which was about 2ft. 6in., and affected the plates on both sides of the lap to a width of from 4 to 6 inches. The rent did not extend longitudinally beyond the limit of this ring of plates, but ran along the transverse seams of rivets on each side of it, almost severing a complete belt from the boiler. The reaction from this opening raised the boiler momentarily almost on end, as was attested by the character of the fracture of the connections, the indentations in the bottom plates, and the fact that a pipe, previously overhead, had become buried beneath it, while the twin boiler alongside was blown bodily in a lateral direction. Had the longitudinal seams of rivets, instead of breaking joint, been in line, which is too frequently the case, the rent would certainly have run from one end of the boiler to the other, and the destruction of property, and very probably that of life also, have been more serious.

"This defect was one that could scarcely have escaped detection on a careful examination of the condition of the plates in the external flues. Still, it should be borne in mind that the plates of boilers set on mid-feathers are neither as accessible nor visible as they are in those set on two side walls with a split flue. The side flues in the latter case admit of coming face to face with the plates and seams in a manner which cannot be done in the former, in which many of them can only be seen obliquely at a very great disadvantage, while those at the upper part of the flue, in what may be termed the tip of the wing, are frequently out of reach altogether.

"All the members must be aware that, for the express purpose of detecting such defects as the above, the Association affords, in addition to the external inspections, the opportunity of having every boiler 'internally and thoroughly' examined at least once a year. The importance of these 'thorough' examinations has been repeatedly called attention to, and every opportunity taken to promote their being made, and, in order to suit the convenience of members as to time, the ordinary routine of visits is entirely set aside at holiday times, such as Whit-week, Christmas, Easter, and race weeks, so that the Inspectors may exclusively devote themselves to this special service.

"It is much to be regretted that the Association was not afforded an opportunity of making a 'thorough' examination of this boiler, either in the year 1860 or 1861, and, when in consequence of attention being specially called to this omission, our Inspector — at the request of the owners — visited the works last Easter, the boiler was found unprepared, the flues being imperfectly swept, and the plates coated with soot, although the visit had been expressly appointed, in order to effect a 'thorough' examination. Under these circum-

stances, no satisfactory examination could be made, which was distinctly stated to the engineer at the time, and subsequently officially reported in writing to the owners. So clearly was this understood, that the next time the boiler was stopped, the manager of the works went up the flues himself in order to complete the examination, which the want of preparation had previously prevented our Inspector from doing.

"It is hoped that our members will see from this the absolute necessity of having their boilers prepared for examination. They certainly cannot fail to remember how constantly this has been pressed upon their attention. A note, referring to it, appears at the foot of every notice forwarded to them, of the Inspector's proposed visit, and another, in the report on his examination, while reference was made to the subject in the Chief Engineer's Monthly Report for June, sent to each member, and, in addition, attention is frequently called by special letter, as it was in the present instance. Had it not been for its practical importance, so much had not been said upon so uninteresting a subject, and apology has sometimes been felt necessary for its frequent introduction. Still, dry or not dry, it is often a question of explosion or no explosion.

"Yet another word before dismissing this subject. To expect an Inspector to wait while the flues are being swept, as is too frequently the case, is really unreasonable, and compliance could only result in the accommodation of one member at the expense of another, while it would induce such disorder and breach of appointments, as would only lead to a general dead-lock, especially in such a thronged time as every holiday week is, when the Inspectors have one continuous string of engagements for these 'thorough' examinations, from its beginning to its close, many of them being fixed for more than a month previously.

"It may be added that the engineer who lost his life had been in the habit of going up the flues every month after they had been swept, and yet did not detect the corroded seam. This either shows that the corroded plate was concealed from view in some way in which it was impossible to account for after the explosion, or else is a witness to the necessity of competent inspection. That sweeps cannot be trusted to do engineering work is also clear.

"L. E. Fletcher, Chief Engineer.

FIRE ENGINES.

The following letter has appeared in the *Times* :—

Sir,—Excellent as are the present arrangements for extinguishing fires, and the machines already in use for that purpose, nevertheless, the unprecedented number and magnitude of the conflagrations which have lately visited the metropolis, have shown the necessity of providing the best possible means of suppressing or controlling this serious and increasing danger.

Recent experiments and experience have demonstrated the great advantage which the steam fire-engine possesses over that worked by manual labour, in the cheapness and facility of working, and in the much greater height and force with which a large and solid column of water can be thrown.

They have not hitherto been brought into general use from the supposed difficulty of getting up steam with sufficient rapidity, and from an apprehension that their weight and bulk would be too much for convenient portability.

These apprehensions are proved to be groundless, but it is felt that much is yet required to perfect the machine, and that it is very desirable to secure the attention of the best practical steam-engine makers to the improvements which may be effected.

For this purpose it is proposed to solicit the aid of fire insurance companies, municipal and parochial authorities, and others interested in the question, towards raising a fund sufficient to invite competition among eminent practical mechanics by the offer of handsome premiums for the best engines.

The chief points to which attention should be directed are: — *Efficiency*, combining facility of drawing water, volume thrown, and the distance to which it can be projected with the least amount of loss; *simplicity and durability of parts; the weight;* and *the cost*.

The undersigned have agreed to co-operate as a committee to carry out this project, and they come before the public earnestly requesting the assistance of all who are interested in the subject, and in the confident expectation that they will not be backward in contributing such an amount as will induce Americans and other foreigners to come forward and compete.

Further particulars will shortly appear in your advertising columns, and in the meantime the committee venture to solicit your advocacy of the cause.

London, July 30.

ON THE UTILISATION OF THE POWER INVOLVED IN THE RISE AND FALL OF THE TIDES.

The tendency of modern scientific discovery has been to show that all the various forms of force with which we are acquainted are mutually convertible into one another. Thus, of the six forces known to us in connection with the universe — gravitation, motion, light, heat, electricity, and chemical affinity — it is well known that any one of the five latter is capable, by appropriate means, of generating the other four; the force of gravitation being capable, through the medium of motion, of giving rise to the other five forces, whilst it cannot itself be generated. Gravitation may therefore be assumed to be the elemental force, since it is the only one of the six which will generate all the others. So accurately have these correlations been studied, that the quantitative value of gravitation has even been ascertained, it having been found that the mechanical force required to lift 772 pounds to the height of one foot is capable, when converted into the force of heat, of raising the temperature of 1 pound of water 1° Fahr. In other words, this amount of heat may be generated by an appropriate utilisation of the gravitating pull exerted by a weight of 772 pounds during its downward movement through the space of one foot. Supposing, therefore, we were in possession of an unlimited number of 772-pound weights, and were to employ in the most judicious manner the force thus evolved in their downward progress, we should have an unlimited reservoir of power, which could be converted at will into light, heat, electricity, or chemical affinity, and could be made to toil for human benefit without any corresponding expenditure of human labour, so long as the weights continued their downward progress unarrested. If, however, any good were to be gained by such a machine, it must be managed so that the motive force — gravitation — should always remain on the pull, and this is, and always will be, the obstacle to the attainment of perpetual motion; the act of overcoming the force of gravity to re-raise the weights requiring the expenditure of exactly the same amount of power as has been generated during their downward fall; and so, before we can seriously discuss the feasibility of such a machine, we must find a perpetual flow of gravitating force always at hand, craving to be satisfied, and yet inexhaustible. In other words, we must construct a clock which will wind itself up when the weight has run down, without any expenditure of human power.

Sitting by the sea-shore a few days since, we could not help noticing the vast reservoir of mechanical power existing in the ocean. We do not refer to the noisy dash of the waves as they break upon the beach, but to the infinitely mightier, although silent and progressive, energy exerted in the gradual rise and fall of the tides. Compared with the stupendous power capable of being utilised for man's benefit, and present in the rise or fall of millions upon millions of tons of water through a space of ten or twenty feet, four times a-day, all the steam, water, or wind power in the world, together with the united muscular force of every living being, human and animal, sink into utter insignificance. We will try to form some idea of this power. Let us suppose that by the action of the tides the difference of level of the surface of the ocean at a certain spot is 21 feet between high and low water; omitting for the present all consideration of the power of the subjacent liquid, what is the mechanical value of a space of 100 yards square of this water? 100 yards square by 21 feet deep equals 70,000 cubic yards of water, which is lifted to a height of 21 feet, or to 1,470,000 cubic yards lifted to a height of 1 foot. Now, since one cubic yard of water weighs about 1,683 lbs., 1,470,000 cubic yards weigh 2,474,010,000 lbs., which is lifted in six hours. This is equivalent to lifting a weight of 412,335,000 foot lbs. in one hour; and since one horse-power is considered equivalent to raising 1,800,000 foot lbs. per hour, we have, locked up in every 100 yards square of sea surface, a power equal to a 230 horse-power steam-engine, acting, be it remembered, day and night to the end of time, requiring no supervision, and costing nothing after the first outlay but the wear and tear of machinery.

By means of appropriate machinery connected with this tidal movement, any kind of work could be readily performed. Water could be hoisted or air compressed to any desired extent, so as to accumulate power for future use, or for transport to distant stations. Light of surpassing splendour could be generated by means of magneto-electric machines; and with a very little exercise of ingenuity, every lighthouse on the coast could be illuminated with sun-like brilliancy, and with absolutely no expenditure of fuel; the very same mechanical power of the ocean which, in its brute force, would dash the helpless vessel to pieces against the rocks, being bound and coerced like the genii in Eastern tales, and transformed by man's intellect into a luminous beacon to warn the mariner against the approach of danger.—*Chemical News.*

HAY'S METHOD OF PROTECTING SHIPS AND OTHER STRUCTURES FROM DECAY.

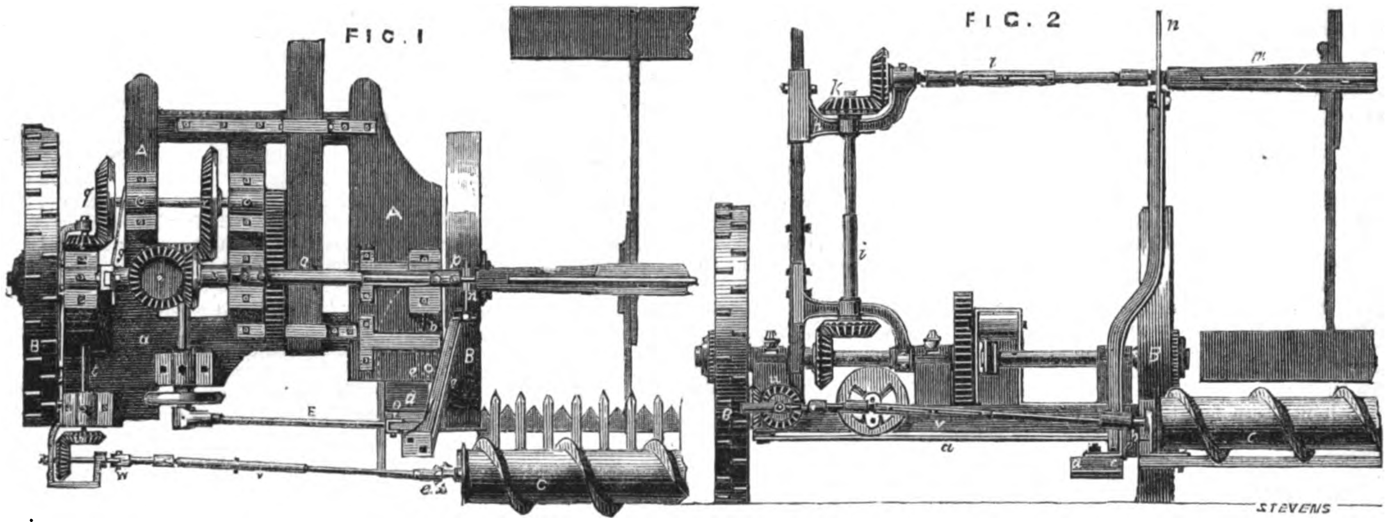
Mr. W. J. Hay, of Southsea, Hants, has obtained a patent for treating the oxides of copper and other metals, to prevent the uncertainty of their action by imperfect or not uniform application, when used for keeping ships' bottoms or other structures free from animalculæ and other animal and vegetable matters; also when used to preserve woods and other materials from decay and the ravages of insects. Black or protoxide of copper is ground and boiled with linseed oil until it is reduced to the suboxide, and by thus oxydising and oxydating the oil, a quick-drying cupreous oil is obtained, which suspends the oxide in the form of a paint or varnish. To this sometimes is added a small portion of silver or other metals and oxides. In some cases where greater durability is required from ships being in foreign stations, or not able to be docked periodically, an additional quantity of finely-ground suboxide or black oxide of copper is added. The paint or varnish may be thinned by spirits of turpentine, naphtha, or any other cheap spirits.

When it is to be applied to iron, one or two protective or non-conducting coats should be first applied. This may be red or white lead, paint or asphalte varnish, or waterproof glue in its liquid state, or other suitable material.

Mr. Hay also proposes to use zinc, either amalgamated or not, in contact with the inside or outside of iron vessels, ships' iron casings and other structures, as a protection against electro-chemical action arising from any imperfect application of the protective varnish, paint, or other material, or from the accidental abrasion of the said protective coatings or otherwise.

BURGESS'S PATENT REAPING AND MOWING MACHINE.

FIG. 1 FIG. 2



Most reaping machines at present constructed are unable, by reason of their great width, to pass along narrow lanes or through gateways. The present invention, patented by Mr. W. Burgess, of the firm of Burgess & Key, of Newgate Street, is intended to obviate this: —

The invention consists, firstly, in means of narrowing reaping, and mowing machines, to facilitate their passing along narrow lanes and through gateways. Fig. 1 of the accompanying drawings is a plan, and fig. 2 a back elevation of a portion of a reaping and mowing machine. To effect the narrowing, the frame A, containing the gearing, is supported upon two wheels B, B: to the lower part of this frame one or more bars *a*, *a*, are attached, which carry one or more travellers *b*, *b*. To the traveller is connected, by means of a hinge joint *c*, a shoe *d*, to which is fixed the finger beam, as also a standard *e*, for supporting the end of the reel next the frame. In order to prevent the traveller from shifting when the machine is at its full width, a hole is made through the back traveller, and a corresponding hole through the frame immediately above it, and a bolt is passed through both holes, as shown. The object of connecting the finger beam and traveller by a hinge joint is that the finger beam, reel, and delivery apparatus may be free to follow the irregularities of the ground.

The invention consists, secondly, in a mode of communicating motion to the reel. This is effected in the following manner: — Upon the axis of the main wheel or wheels is fastened a bevel wheel *f*, and by means of a collar on and through which the said axis is free to revolve, a standard *g* is fitted, and it is maintained in an upright or inclined position as may be required in the adjustment of the reel or otherwise by means of a stay. The stay is pierced with holes, and the standard is secured by a pin or bolt, which also passes through a hole in the standard fitted with two brackets *h*, *h*, to carry a vertical shaft *i*. The lower of these brackets is fixed, but the upper bracket may be raised or lowered at will (according to the height of the reel); at the lower extremity of the said vertical shaft is fastened a bevel wheel, which gears into the wheel on the main axis; higher up on the vertical shaft, and supported by the upper bracket above mentioned, is a bevel wheel *k*, so attached to the shaft as to revolve with it, but at the same time capable of sliding up and down on it according as the bracket which supports it is raised or lowered. The bevel wheel communicates motion to another bevel wheel, keyed on to a horizontal shaft *l*, supported at one end by the movable bracket and connected at the other with the reel shaft *m*, to which it imparts rotary motion. The horizontal shaft is formed with a tube or tubes, in which one rod or more fitted with universal joints is free to slide for the purpose of allowing the shaft to contract or extend according to the lateral movements of the reel in going over uneven surfaces. The standard *g* attached to the axis is capable of being moved more or less out of a vertical position by turning it on the axis, and by this means, together with an appliance to the standard *e*, which supports the end of the reel shaft next the frame, the reel may be raised or lowered, or placed either forward or backward as required. The arrangement adopted for this purpose is as follows: — On the top of the standard *e* a T rod *n* is fixed. This T rod is moved up and down and fixed in the desired position by means of a bolt, passed through holes in it and in the standard *e*. *p* is a traveller which carries the end of the reel-shaft, and is free to travel on the leg of the T rod. The motion for driving the delivery apparatus is communicated from the second-motion spindle, similar gearing being used to that employed for driving the reel; *q* is a bevel wheel on the second-motion spindle *r*; *s* is a beveled pinion on the shaft *t*, geared into by the wheel *q*, and giving motion through a pair of beveled pinions *u*, *u*, to a horizontal shaft *v*, similar to that employed for communicating motion to the reel shaft *m*, and fitted with a hinge *w*. The shaft *v* is connected to the apparatus C for delivering the cut crop from off the platform of the machine, and imparts motion to it.

FIG. 3.

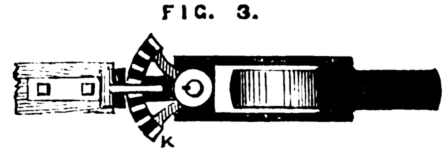


FIG. 4.

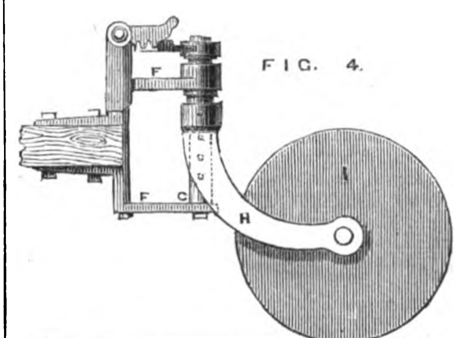

In order to narrow the machine, the bolts before mentioned are removed, which enables the upright standard *g* to incline forward; the knife bar D is disconnected from its connecting rod E, the shaft *v* is turned upwards upon the hinge *w*, and the travellers are slid along the bar or bars *a*, *a*, when the reel and the cutting and delivering apparatus will all move inwards to the extent to which the travellers are made to slide. In some cases a swivel wheel is used, which is free to follow behind the machine; the wheel is fixed in a frame, through the front of which a rod passes, so arranged that the wheel and frame can be raised or lowered on the rod so that the knife can be placed at any required height from the ground; on the top of the rod is fixed a quadrant, on the face of which are notches, and a trigger is so placed that it can be made to fall into one of the notches, so as to prevent the wheel from turning out of the line of draught of the machine when being backed. This swivel wheel, quadrant, and trigger are shown in plan and side elevation at Figs. 3 and 4. F, F, are supports fixed on to the back of the frame of the machine; G is a rod with holes, free to turn in bearings in the supports F, F; H is a frame carrying the wheel I, through one end of which the rod passes; the position of this frame on the rod G is regulated by a pin which is passed through an aperture formed therein and through one of the holes in the rod G; K is a quadrant with notches on its face, fixed on the top of the rod G; L is a trigger which, when required, is inserted into one of the notches to prevent the frame in which the wheel is fixed from turning when the machine is being backed.

MR. GLADSTONE ON ENGINEERS.

At the inauguration of the statue to Sir Hugh Myddelton, Mr. Gladstone concluded an eloquent address with the following observations upon engineers:—"It is a thing somewhat new in the history of mankind to erect in public places the statues of engineers. If we go back to the very first roots and beginnings of philosophy, we shall find that whatever related to mechanics and to physical force was associated with strictly and purely mental inquiries; but they soon came to be divorced one from another, and thousands of years elapsed before the engineer, as such, came to be recognised as a person having a high title to public distinction. It does not appear that the people of this country in very early times had developed much of the talent for which they are now so remarkable, and thus we see, in reviewing the history of the nation to which we belong, that at the later period of its career it has exhibited aptitudes of which there was no

trace at an earlier period. Let me say, in passing, that that is a useful lesson, not for nations only but for individuals, for it may teach an individual that there are many things at present wholly beyond his power, and for which he cannot even recognise in himself materials and fitness, and yet to which he may thoroughly and conspicuously attain by assiduous and resolute cultivation of the faculties which God has given him. No doubt the engineers who, under the name of architects, erected the cathedrals of this country, must have been persons considerable in their profession; but for much of their education we are indebted to foreign countries. It was rather in the main an imported than an indigenous quality; but in these later times we have seen a great change, and the engineers of this country have taken their place as one of the most important and most distinguished classes of the community. They have fairly taken their place amongst the great men of England; and I do not know whether any commemoration has yet been given to any of them so conspicuous as the erection of this statue of Sir Hugh Myddelton in one of the greatest thoroughfares of this vast metropolis. It is a fact full of meaning; it is an indication of the movements of the times, and the development of those faculties by which man is fitting himself more and more by the efforts of each generation in succession to contend with those difficulties of outward nature amidst which Providence has placed him for the purpose of evoking his energies, and to make the gifts and bounties of Providence available for his comfort and his happiness. This is the opening almost of a new chapter in the condition of man. I do not mean that it is the beginning of such efforts, but it is the beginning of them on a new scale, with a new system, with new appliances, and with new means for the intercommunication and interchange of knowledge; and it marks the fact that in the list of elements that belong to human civilisation these great operations of art and science, applied to the external world, must henceforward be included, and hold a conspicuous place; and it will be our own fault if the addition of that new chapter fail to be a great blessing. There is no reason why it should displace anything; and therefore let us not see in the distinctions bestowed upon the engineers anything that need fill us with fear or apprehension; and do not let us see in it the displacement of whatever has been done by man with respect to religion, art, or ancient learning. All these things ought to continue to grow and thrive, and that which we introduce we ought to add to what we have enjoyed before, and not substitute for what we have been enjoying. It is an immense blessing—it is a work of which we may confidently say that it is acceptable to God as well as to man—when water is brought from a distant spot to supply the population of this great city. It is all very well for most of us who are assembled here to make light of these great appliances of modern engineering, and to think that it does not signify whether we are carried fifty miles an hour or five—whether our houses are well drained or not, and whether the water of the country is brought to feed London. It is all very well for us to assume a high and sanctimonious tone and say, 'Do not let us overwhelm these temporal goods and comforts.' It is wise that the poor should be remembered; and I have no doubt that the ministers of religion will take care to remind them that they are not to suffer their minds to be absorbed and dried up with the continual contemplation of temporal and physical necessities, but ever to lift their eyes up to the God that is in heaven; but language such as that need not be held amongst the wealthy. Let us freely and gratefully acknowledge that those who, like Sir Hugh Myddelton in former days, devote themselves with energy, forethought, care, and skill to the multiplication of appliances which conduce to the comfort of man, and to conquering the forces of nature and making them subservient to human happiness, are doing a great and good work before the face of Heaven as well as before the face of man, and deserve to be held in grateful honour as real and genuine benefactors of mankind."

JEAUNEAU'S ROAD-SWEEPING MACHINE.

FIG. 1

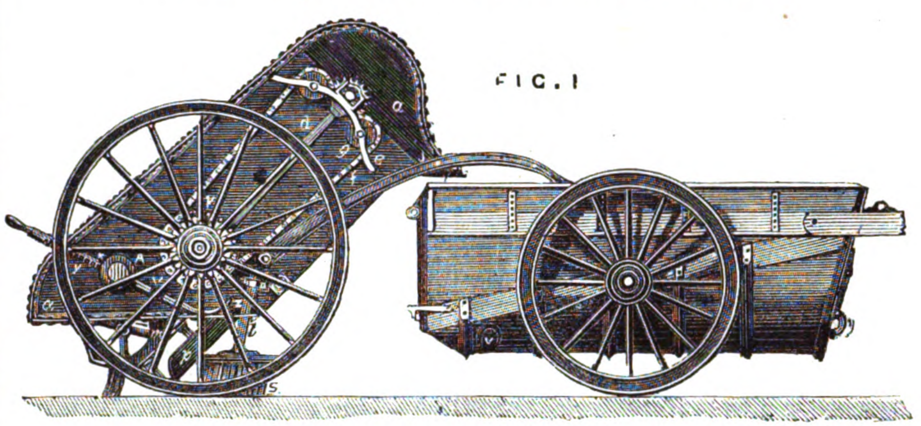

FIG. 2

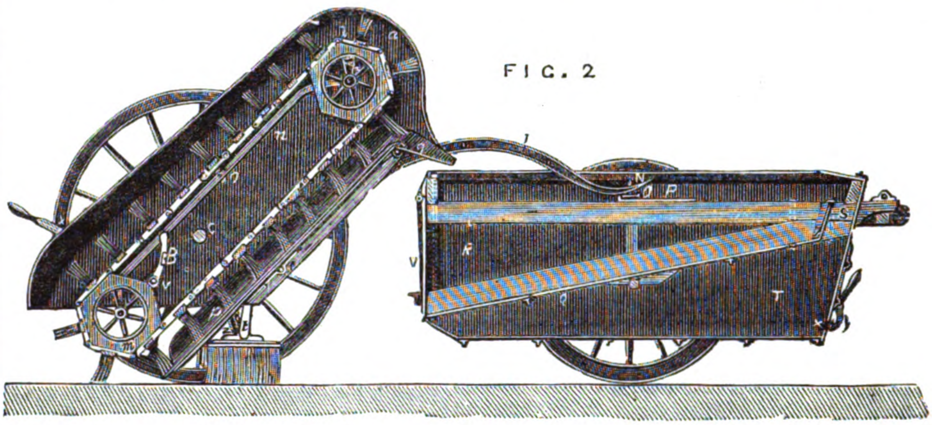

Monsieur Jeauneau, of Cosne, France, has patented an improved machine for sweeping roads and streets, parts of the machine being applicable to separating liquid from solid substances.

Fig. 1 of the accompanying engravings is a side elevation, and fig. 2 is a longitudinal section of a sweeping machine, constructed according to this invention. *a* is the case or frame, made by preference of sheet iron, and strengthened by angle pieces and supports. This case is open at the end. *c* is the main or driving axle which passes through the sides of it. *d* is a guide bar terminating in a bracket *e*, supporting the bearing *f* and the pulleys *g g'*. The axis *h*, on which the pinion *i* is keyed, is free to revolve in the bearing *f*: this pinion gears into the teeth on the endless chain *j*, which is driven by the toothed wheel *k* on the axle *c*. *l* is a polygonal drum mounted on the axis *h*, inside the case *a*. This drum is connected to another and similar drum *m* by means of the frame *n*; a roller *o* supports the weight of the chain. During the upward motion of the brooms, the dirt is drawn into the passage *p* to the shoot or guide *q*, and thence into a receiver. The conduit *p* is free to move upon an axis *r* in such manner as to remain parallel with the chain of brooms, however much the latter may be worn. *s s* are side brooms, one only of which is seen; they are placed at an angle with the line of draught, so as to guide the dirt into the line traversed by the brooms. These brooms *s s* are united to knee-pieces *t*, which slide in a guide fixed outside the case *a*. The height of the chain of brooms from the ground is regulated in the following manner:—On the shaft *v*, which is fixed to the case *a*, the lever *x* is free to move, the position of the weight A being regulated by the rack *y*. To this lever *x* the forks B are fixed, so that by depressing the end of the lever *x* the frame *n* is pushed back, and, consequently, the drum *m* and with it the chain of brooms is raised from the ground. A similar motion of the lever *x* raises the side-brooms by means of the chain *z*, which is fixed to its other extremity. A chain is used in preference to any other connection, because, by means of the links of which it is composed, its length can be easily adapted to suit the wear of the brooms. The clutch arrangement D slides on a collar on the shaft *c*, and abuts against the springs E fixed to the outer side of the case *a*. The clutch is provided with inclined catches, which take into corresponding apertures formed in the nave F of the driving wheel. The springs E tend to press the clutch against the nave of the wheel, so that when the machine advances the running wheel draws with it the clutch as well as the wheel *k*, which forms part of it. If the machine moves in a contrary direction, or backwards, the box F presses against the teeth of the clutch D, which compresses the springs E and stops the motion. G is a bearing fixed to the frame *a*. H and I are internal and external strengthening pieces for supporting and keeping together the case or frame of the machine. The chain *j* is composed of metal plates held together by pins on each side, and which enter the notches in the toothed wheel *k*. The pinion *i* is arranged in a similar manner. Any other construction of toothed wheel and chain may, however, be employed. The sweeping machine is attached to the receiver by shafts J J fixed to the sides of the frame; the ends of these shafts are united to form a sort of stay, through which a gudgeon N passes, fixed to a horizontal metal cross-bar O. This cross-bar is itself held by two hooks P placed on each side of the receiver, which is divided centrally by the inclined partition Q. The dirt, rubbish, mud, and materials which are swept up the conduit by the brooms and thence conveyed by the spout *q*, first fall into the compartment R, the liquid portion passes to the compartment T by the aperture S, while the heavy portion sinks in the compartment R, from whence it is removed by the door U. V V are apertures one on each side of the receiver, but one only of which is seen, by which the contents of the compartment T are emptied. When it is desired to use the liquid portion for watering the road, the orifice X is opened by raising the plug Y, which is fitted with a rose or spreader. By

the construction of this apparatus streets and roads are swept, the mud is washed, the sand extracted from it, the liquid portion thereof employed for watering the roads, and the heavy thrown into sewers or other receptacles for manure and other purposes.

NOTE ON THE HISTORY OF THE DYNAMICAL THEORY OF HEAT.

By J. P. Joule, LL.D., F.R.S.

To the Editors of the Philosophical Magazine and Journal.

Gentlemen,—Will you permit me to trouble your readers with a few remarks on the subject of my friend Professor Tyndall's lecture at the Royal Institution, reported in your last number? In this lecture he enforces the claims of M. Mayer, a philosopher whose merit has perhaps been overlooked by some of our English physicists, and unaccountably so by his fellow-countrymen. I myself was only imperfectly acquainted with his papers when, in good conscience and with the materials at command, I gave a sketch of the history of the dynamical theory of heat, in my paper published in the Philosophical Transactions for 1850. M. Mayer's merit consists in having announced, apparently without knowledge of what had been done before, the true theory of heat. This is no small merit, and I am the last person who would wish to detract from it. But to give to Mayer, or indeed to any single individual, the undivided praise of propounding the dynamical theory of heat, is manifestly unjust to the numerous contributors to that great step in physical science. Two centuries ago, Locke said that, "Heat is a very brisk agitation of the insensible parts of the object, which produces in us that sensation from whence we denominate the object hot; so that what in our sensation is *heat*, in the object is nothing but *motion*." In 1798, Rumford, inquiring into the source of heat developed in the boring of cannon, observed that it was "extremely difficult, if not quite impossible, to form any distinct idea of anything capable of being excited and communicated, in the manner the heat was excited and communicated in these experiments, except it be motion." In 1812, Davy wrote, "The immediate cause of the phenomena of heat, then, is motion, and the laws of its communication are precisely the same as the laws of the communication of motion";* and he confirmed his views by that original and most interesting experiment in which he melted ice by friction. In 1839, Séguin published a work entitled "De l'Influence des Chemins de Fer." He shows that the theory generally adopted would lead to the absurd conclusion that a finite quantity of heat can produce an indefinite quantity of mechanical action, and remarks (p. 328), "Il me parait plus naturel de supposer qu'une certaine quantité de calorique disparait dans l'acte même de la production de la force ou puissance mécanique, et réciproquement." At p. 383 he remarks, "La force mécanique qui apparait pendant l'abaissement de température d'un gaz comme de tout autre corps qui se dilate, est la mesure et la représentation de cette diminution de chaleur." In p. 389 he gives a Table of the quantity of mechanical effect produced corresponding to the loss of temperature of steam on expanding. From this it appears that 1° Cent. corresponds with 363 kilogrammes raised to the height of 1 metre. At p. 403 he states, "Je bornerai là mes réflexions sur un sujet dont chacun saura apprécier l'importance. Du calorique qui est employé par l'industrie à produire de la force, et aux usages domestiques, une faible partie seulement est utilisée; une autre quantité bien plus considérable, et qui pourrait suffire à créer d'immenses valeurs et à augmenter d'autant la richesse nationale, se trouve absolument perdue." From the above extracts, it will be seen that a great advance had been made before Mayer wrote his paper in 1842. Mayer discourses to the same effect as Séguin, but at greater length, with greater perspicuity, and with more copiousness of illustration. He adopts the same hypothesis as the latter philosopher, viz., that the heat evolved on compressing an elastic fluid is exactly the equivalent of the compressing force, and thus arrives at the same equivalent, viz., 365 kilogrammes per 1° Cent.

It must be remarked that, at the time Séguin and Mayer wrote, there were no known facts to warrant the hypothesis they adopted. There was no reason to assert that the heat evolved by compressing a gas was even approximately the equivalent of the compressing force. This being the case may account for the inattention of the scientific world to these writings. The dynamical theory of heat certainly was not established by Séguin and Mayer. To do this required experiment; and I therefore fearlessly assert my right to the position which has been generally accorded to me by my fellow physicists as having been the first to give a decisive proof of the correctness of this theory.

In saying this I do not wish to claim any monopoly of merit. Even if Rumford, Mayer, and Séguin had not produced their works, justice would still compel me to share with Thomson, Rankine, Helmholtz, Holtzman, Clausius, and others, whose labours have not only given developements and applications of the dynamical theory which entitle them to merit as well as their predecessors in these enquiries, but who have contributed most essentially in supporting it by new proofs.

Permit me to remark, in conclusion, that I applied the dynamical theory to vital processes in 1843;* and that in 1847, in a popular lecture published in the *Manchester Courier*, I explained the phenomena of shooting-stars, and also stated that the effect of the earth falling into the sun would be to increase the temperature of that luminary.† Since that time Thomson, by his profound investigations, has made the dynamical theory of heat, as applied to cosmical phenomena, his own.

I sincerely trust that, by the foregoing remarks, I have done no injustice to Mayer, especially as I grieve to hear that sickness has removed him (I hope for only a short time) from the science to which he has contributed with so much ability. The reproduction of some of his papers in the "Philosophical Magazine," particularly that "On the Forces of Inorganic Nature," would, I am sure, interest many of your readers, and enable them to fully appreciate his just claims.

I remain, Gentlemen,
Yours respectfully,
J. P. Joule.

THE PHYSIOLOGY OF SEA-SICKNESS.‡

By Richard Meade Bache,
Assistant U. S. Coast Survey.

All that is known about sea-sickness is, that certain involuntary motions of the body produce an effect upon the nervous system. This effect results in nausea. This nausea is called sea-sickness. The question is not solved, as to the manner in which the nervous impression is produced.

It is generally supposed, that sea-sickness is produced by the mere motion of the body, and consequently of the stomach. That it is produced by motion, is not to be denied, but as wherever sea-sickness occurs, motion is the pervading concomitant of existence — the thing most patent of all that is evident to the senses, and the body is so unpleasantly subjected to it, we lose sight of the fact, that with the body are also subjected all the senses or perceptive faculties, and that these are called upon to comprehend an entirely novel state of existence.

I have said, that the mere action of motion upon the body is supposed to produce the nausea called sea-sickness. I hope to be able to overthrow this theory by the arguments and proofs of another theory, which I am about to advance.

The points which I intend to prove are — that the agreeableness of motion is a mere matter of habit—that motion, however violent, is not nauseating per se, but only inasmuch as it produces an impression conflicting with its ordinary contrasted effects as pre-established in the mind, that the idea of motion is the result of concurrent testimony of the senses—and, that in novel motions, there is a violation of the conception of motion derived from the habitual concurrence of the testimony of the senses—that as the result of this violation, a conflict of impressions ensues, and the brain is affected—thence the nervous system, and nausea results. In fine, I maintain that sea-sickness is a disease of the brain, and not of the stomach, except incidentally, or as affected by the brain, although it is true that the stomach reacts upon the brain.

I now commence my argument, in which I have attempted a procedure which, I trust, cannot fail to bring conviction of the truth of the theory to any one who will carefully analyse it. In all statements of facts which I have introduced I have taken the experience of others, as well as my own.

The appearance of motion when the observer knows that his own body is at rest, is not nauseating. To ascertain the effect of the mere appearance of motion under these circumstances, we can take no better example than that of a train of cars drawn by a locomotive at full speed. The more rapid motions of the heavenly bodies are not appreciable by our senses. We have conception of them through the mind, but not through sight or hearing, therefore I have chosen the motion of railway trains for the purpose of illustrating the effect of the mere appearance of motion. Standing as near or as far off as one pleases, from a train of cars in rapid motion, no more nauseating effect is produced upon the spectator than by the sight of any object at rest. Yet the appearance of motion is nauseating in *two* cases—but these are where the idea of motion of the body is involved, that is where motion of the body of the observer is either in *debate* by the mind, or *acknowledged* by the mind and the motion is not *felt*. If this can be made to appear, it is additional proof that the mere appearance of motion is not nauseating, or as I shall henceforth express it for convenience, the appearance of motion is not nauseating per se. As an example of the first case—that the appearance of motion is nauseating "when motion of the body of the observer is in *debate* by the mind"—take the following: In a dimly-lighted depôt, two trains of cars stop side by side—presently one starts—so gently that an occupant of one of the trains cannot decide whether it is his own train which is in motion, and consequently whether it is his own *body* which is in motion, or whether the motion perceived is that of the other train. This produces a sensation of uncomfortableness — of giddiness — indicative that nausea would result if the effect were continued. At all events, it produces an impression of motion of the body, which impression is derived through the instrumentality of the sight, and which impression affects the nervous system unpleasantly—yet the body of the observer may have been at rest all the while. As an example of the second case—the assertion "that the appearance of motion is nauseating when motion of the body of the observer is *acknowledged* by the mind, and the motion is not *felt*," one illustration, as in the first case, will suffice. In the slight trembling of an earthquake, when the jar would have escaped notice but for the faint oscillation of a chandelier which calls attention to the existence of an earthquake—this oscillation, through the impression which it gives the observer that his body is in motion, often causes the sensation of nausea. It is impossible that the motion of the body of the observer could cause the sensation, for the case spoken of is one where the existence of the earthquake would not have been known, but for the oscillation of the chandelier. The sensation could not have proceeded from the mere perception of the motion of the chandelier, because such an object can be viewed while swinging violently, without any sensation being produced, other than the perception of its swinging.

The cause of the disagreeable sensations just described, is owing to the fact that nature requires our senses to keep pace. The sight must not proclaim what the feeling does not at once corroborate,

* Elements of Chemical Philosophy, p. 49.

* Phil. Mag. S. 3. vol. xxiii p. 442.
† Ibid. vol. xxxii. p. 350; and *Manchester Courier*, May 12, 1847.
‡ Read before the Connecticut Academy of Arts and Sciences, January 15, 1862.

and vice versa. In the first case, nervous impression was produced by doubt in the mind of the observer as to whether his body was or was not in motion, and in the second case, by the consciousness of motion of the body, which motion was not *felt*. In neither case did the senses keep pace, consequently the nervous impression ensued, and consequently nausea. It is evident, although the sight was the agent in these results, that it was *only* the agent, and it was the imagination which produced the effects. Sight was the intermediary. It may be safely inferred from the effect of the appearance of motion in the two cases just cited—that if a man, believing himself in his senses, should see a landscape glide by, he would become nauseated, yet it is evident that the nausea would proceed from the involved idea of motion — the idea that he might be in motion without feeling it —for if he knew it was only the landscape which he saw that was in motion, he would regard it with terror, but without other sensation, and it would affect him as a passing train of cars when he knew that his own body was at rest—that, is, it would not affect him at all, as far as nauseation is concerned.

We see, then, that the appearance of motion per se does not nauseate, and we see too how the nervous system is impressed by the imagination so as to bring about nausea.

The senses from the earliest infancy have grown up and been educated together to act in harmony. It requires habit to render them capable of keeping pace together in a novel condition of existence. The motion communicated to the body by riding in a carriage is by no means violent, notwithstanding which, persons in early life frequently become nauseated while thus riding. This is merely because the sense of sight and the feeling of a certain motion have not been educated together. This I shall proceed to show. It is well known that persons perfectly habituated to riding in a certain position in a carriage, object to riding with the back towards the direction in which they are proceeding, on the plea that it makes them sick to do so. It doubtless has that effect, but it is impossible for the effect to be produced by the mere motion in that position, for it is impossible, in a carriage in motion in the dark, to decide in what position one is sitting in relation to the line of progress, unless some obstacle should interpose, or the road should be so bad as to afford an equivalent to a number of obstacles in the way, or unless the driving is of such a character, by sudden turnings and abrupt increasing or slackening of speed, as to indicate to the occupant of the carriage the position in which he must be sitting. In a word, in ordinary conditions of progress in a carriage, it is impossible in the dark to determine in what position one is sitting. This is not generally known. Experiment will prove my assertion to be true.

It has been already shown that the appearance of motion per se does not nauseate. How then is a person accustomed to riding in a carriage nauseated by riding with the back towards the direction in which he is proceeding, for the appearance of motion per se does not nauseate, nor can motion per se nauseate in *that* instance. The effect is derived from consciousness of motion perceived by two senses at least, while at the same time the appearance of objects violates the habitual impression produced by the sight of them. In the dark, the effect must be derived from pure imagination. If we grant then that a particular mode of progress in a carriage can nauseate one accustomed to a carriage (and it is often seen), and we grant at the same time that appearance of motion per se is not nauseating (and this I have proved), and we know also, in the case spoken of, that motion per se could not have produced the sensation of nausea (because the motion is the same in any position, and the person is habituated to one), we must then acknowledge that the nausea is produced neither by the motion per se, nor by the appearance of motion per se, but by a conflict of the two senses of feeling and sight. If this can be inferred in the case of one accustomed to the motion of a carriage, it must apply with more force to one unaccustomed to it.

So thoroughly have the senses created a conception of motion, that the exclusion of sight does not alter the idea of its appearance, nor alter the idea of the appearance of violation of preconceived effects. The mental picture is always present. If the exclusion of the sight did alter these ideas, the closing of the eyes would, in one of the cases just mentioned, save from nausea a person unaccustomed to riding in a certain position, and in the other case would secure immunity from nausea to the person unaccustomed to riding at all. But it does not save them, which shows that the mental picture of progress and of unwonted effects takes the place of that produced by actual vision. It is immaterial whether the sight is acting or not acting. Whatever senses exist in an individual, have conjointly created a well-defined idea of the contrasted effects of motion, and this conception is always evident to the mind without the continued intervention of all the authors of the conception.

Having shown that a certain motion is nauseating, but is not nauseating per se, we may fairly infer that no motion is nauseating per se. Perhaps in very violent motions, there may be some mechanical effect produced by the movement of the stomach — this is not a primary cause of sea-sickness, but an aggravation of it. Otherwise, it must be supposed that the stomach of a sailor becomes entirely changed in its nature.

The law to be deduced from what I have attempted to demonstrate is this — that the violation of the habitual conception of contrasted effects of motion, is the cause of the nauseation which occurs during novel motions — and the cause is not motion per se, nor the appearance of motion per se.

If such effects as those just described in the case of riding in a carriage can nauseate when they are produced by comparatively slight changes in "the habitual conception of contrasted effects of motion," it is not surprising that the effect of motion at sea should bring the great and continuous nausea called sea-sickness. The motions of a ship vary infinitely. As soon as a certain kind of motion has lasted for a long time, the voyager becomes accustomed to it, and he has no more tendency to become nauseated than has the man accustomed to a carriage. He may, however, become sick again if the motion should vary and yet not be increased. A person habituated to the sea may remain ashore for a long time, but his senses readily accommodate themselves again to conditions once understood. It is true that even old sea captains are sometimes afflicted by sea-sickness, but this does not invalidate the theory which I have advanced. There are temperaments so predisposed to sea-sickness, that the inuring process has to be perpetually renewed. I do not assert that the same amount of experience at sea gives the same immunity to each person. The causes which I have mentioned as superinducing sea sickness affect every one, but the capability of resisting it varies with every temperament. There are individuals who never become sea-sick—that is to the extent of succumbing to nausea — but they undergo the same process of education of the senses. The difference between these persons and those who do succumb, is that their organizations in physique and temperament enable them to resist the inclination to nausea, and the education of the senses is completed before nausea has been able to overcome them, although it always attacks. There is no one who in a first experience at sea is not disposed to nausea, but there are some few persons who possess such organisations that, with the aid of a firm determination to resist an attack of sea-sickness, they are enabled to escape it, and to pass the ordeal of the novel motion at sea without manifest inconvenience.

(To be concluded in our next.)

It is said that a contractor for guns for Government is making one hundred and fifty thousand pounds a year profit!

THE STRAIGHT LINE *VERSUS* THE WAVE LINE FOR VESSELS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR, — Mr. Cheverton's request is very curious, "that I would hand over the defence of the wave line theory to some one more competent to discuss it." I have already several times referred him to Mr. Scott Russell's elaborate papers; Mr. Cheverton does not say whether he has done so; but, alas for me, he condemns Mr. Scott Russell and Mr. Macquorn Rankine as well as my humble self. Being censured in such company, I really must imitate Lord Palmerston, and say I am proud to differ from him.* Before attacking any established scientific fact, it is generally considered not only prudent but absolutely necessary to become acquainted with the best works upon the subject; but I must conclude that Mr. Cheverton either has found the royal road to learning, or is profoundly ignorant of the subject he writes upon.

Mr. C. says, "the adoption of hollow lines is rather prevalent, and it is much to be regretted that it should be so, if the practice is bad." Just so say I — *if the practice is bad!* But it so happens that the practice is good; and so good that if a man wants speed in his vessel he adopts the wave line system and obtains it; and almost every fast ship in the world is constructed upon that system, more or less fully carried out. And I can tell Mr. C. that the Warrior and many other well-known vessels could not carry power enough to drive them at their present speeds with straight line bows of the same length as those they have on the wave line system.

Mr. Cheverton says, "Mr. Moy will excuse me from noticing his observations on uniform motion; they are, I can assure him, random remarks, without pertinency or point."

I am not in the habit of making *random remarks*, and my observations I consider exceedingly pertinent to the question, and I now repeat them in the strongest language I can use: *that there is no possibility of forming the bow of a vessel in such a manner as to drive the water from the central line of the vessel's course to its sides, at an uniform velocity.*

I will now show that the straight line bow cannot produce uniform motion. Take the example of the pier of a bridge in a tide-way, many of which may be found with straight lines beginning at an angle and joining the sides with a short curve. The water becomes heaped up at what may be termed the stem, from its motion being suddenly arrested, and the impossibility of its motion being as suddenly diverted in a new direction. By thus rising in the form of a bow wave it is enabled to run down hill towards the sides, which it does at a very irregular velocity, and when it has arrived *just so far as it should go and not a jot farther*, it has gained too high a velocity in this direction and shoots beyond the sides of the pier, and, in passing the pier, encloses a mass of dead water between the moving water and the pier. This clearly proves that the straight line fails to impart uniform motion, and, even with the help of a curved junction with the side, fails to transfer the water quietly to its new channel.

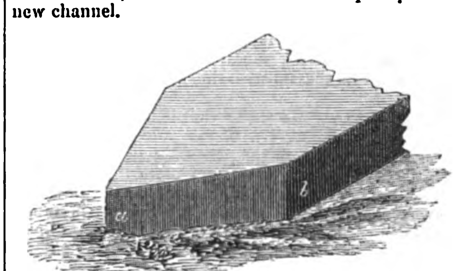

Fig. 1.

Again, let *a b*, fig. 1, be the bow of a vessel (shown in perspective) formed on the straight line in its

* To the disgrace of Lord Palmerston.—ED. M. M.

integrity. The water met at the stem a should pass quietly to b, to do which it is requisite to pass suddenly into lateral motion at a, and as suddenly to lose that lateral motion at b. Nothing of the kind, can however, take place; but a similar bow wave, as in the case of the pier of a bridge just mentioned, will arise, with the same irregularity of motion.

A word or two now about the wave line. Let the end of the extended guide rod d of the slotted cross-head and piston rod, fig. 2, mark out the form of bow

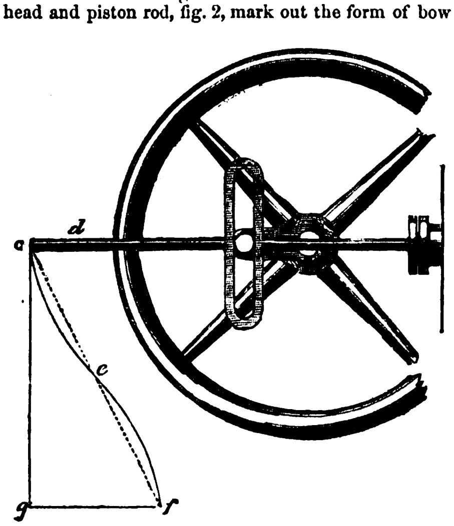

Fig. 2.

we want. Let $c\ g$ be the length of bow required, $g\ f$ the half breadth of the beam. Let the fly-wheel revolve at an uniform velocity for half a revolution, drawing (by its crank pin) the slotted cross-head, &c. back towards the cylinder. At the same time, let $c\ g\ f$ be moved also at an uniform velocity, so that when the piston has completed its in-stroke the point of d will touch f; this will trace the curve $c\ e\ f$. The dotted line is the straight line bow. The perfect line is the wave line.

Now with this form, at c the water is gently forced to move, at e it has attained its greatest velocity, and from e to f it gradually loses that velocity, at f it has no motion whatever, it has been moved as far as is necessary, *and not a jot farther*; no *vis viva* remains in it. You may now continue with a parallel middle body, or the stern curves may at once commence; no dead water is dragged along the side, simply because no attempt is made to treat the water unnaturally, no sudden and violent motion is attempted, but the form of bow is made to accommodate itself to the nature of the element upon which it must act.

I am, Sir,
Your very obedient servant,
T. Moy.

1 Clifford's Inn, Aug. 4, 1862.

THE "SLEEPING PARTNERS" OF ELSWICK.

Sir,—The zeal which you have manifested in opposition to the notorious "Armstrong gun" job is well worthy the notice of the Legislature; and Mr. Bernal Osborne's remark, "the sleeping partners of Elswick," is full of meaning; but the "sleeping partners" must be named, and that without reserve, before the public can hope to be relieved from this expensive gun job, of which we have all a right to complain.

The justice of the question is ignored by "back-door" influence; and so it will remain until the Legislature shall have the moral courage to require the names of all mixed up with this great national delusion.

Mr. Bernal Osborne states that it has already cost about or over 3,000,000*l.* of the public money, and that England is not in the possession of a single gun such as her future interest and protection demand. Of this I am very well aware; and I am also aware, as every honourable man must be, if it is attributable to the demoralising party compact which still forces this costly gun into use, it is the duty of the House of Commons to demand an open and full investigation instanter into the secrets of this notorious State transaction; and, although I am not prepared to say that all I have been told, and all I have read in your valuable Magazine and other professional papers, be literally correct, I know quite enough to be in a position to state, the Government is bound to make public what it knows, and that it knows quite sufficient to put a stop to the practices resorted to to keep up the delusion.

It is well known, in the first place, that Major-General Peel, when Secretary of State for War, handed over about 8,000*l.* of the public money to a Mr. William Armstrong, to make the first example at Newcastle; and it is also well known, after the example gun was made, Major-General Peel adopted the gun in the service, and gave to Mr. William Armstrong a public grant of 20,000*l.*; and subsequently that the Government made Mr. "Sir" William Armstrong, for his presumed services in this delicate affair; but it is not so well known as it should, that Major-General Peel refused to ascertain the merits and justice of the question before he undertook to close the bargain with the "sleeping partners" of Elswick.

That the then Mr. Armstrong and the Major-General were not of sufficient importance to do this thing on their own responsibility, every reasonable man must be aware; and it is much to be regretted that the "free institutions" of this enlightened country should admit of covert irresponsible influence to complete what two individuals of minor importance in the State could not venture to undertake unknown to those who, we are told to believe, are responsible for the expenditure of the public money.

How many there may be directly and indirectly interested as "sleeping partners," I am not aware; but if there be six, each must have shared a very considerable trade profit out of the amount, 3,000,000*l.*, as named by Mr. Bernal Osborne.

The trade profit cannot amount to less than 700,000*l.*; or at the rate of or above 100,000*l.* for each, if there be six "sleeping partners" in the Elswick gun firm — a nice little sum to be cleared in or about four years; and it is not very surprising that every effort to get at the truth should be so patriotically burked by those who have the power, under present painful circumstances, to keep up the works at Elswick. Major-General Peel, if called upon, can surely name the parties with whom he entered into a bond of 85,000*l.*, to keep up the Armstrong gun establishment; but if he should presume not to recollect, Sir George Cornewall Lewis can produce all the papers to be found at the Pall Mall establishment; and no doubt he will gladly do so if Mr. Bernal Osborne, or any other member of the House of Commons, will press the subject to a clear and honourable conclusion.

It is presumed by many, the "sleeping partners" are too strong to yield to the wishes of the Legislature, or that it will be injurious to the credit of the State to make everything known from the beginning, so far as the "Armstrong gun" is concerned; but this, in my humble opinion, is a very injurious fallacy, and the sooner exploded the better; but if the members of the House of Commons are inclined to dispose of the question more promptly, let them pay over to the "sleeping partners" of Elswick the 85,000*l.* bond, and have done with the question; and Sir Cornewall Lewis will then be free, and, as it is to be hoped, will at once proceed in procuring such a gun as we are assured the public service is much in want of.

Observer.

London, August 4.

SHOT-PROOF SHIPS.

Sir,—It is stated in your number of the 18th inst., that proposals and plans under this head submitted to the Admiralty between May 1, 1859, and May 1, 1862, amounted to 590. Is it to be understood by this return that there was no suggestion of the kind made prior to May 1, 1859, because, as a matter of historical truth, I beg to state that I hold letters which show that I proposed to Sir James Graham to construct vessels shot-proof of iron, as early as May, 1854? The leading feature of my plan consisted in forming the outside shell of iron plates placed so as to receive the impact of a shot on their edges, similar to a model now at the Royal United Service Institution, but the idea of making wooden vessels invulnerable to Artillery by covering them with armour-plates never entered my head as practicable; I directed my attention to this subject some ten years before, when news reached England that shot had perforated one of Her Majesty's ships in the Rio de la Plata. It was then first found out, or erroneously supposed, that iron was not adapted for ships of war; it appeared to me, however, that if a ship were made of iron as strong as the iron breech of a gun, a fulcrum for the force which projected a shot, it would not penetrate the former. The defect lay in the way of using the material, not in the material itself. The ultimate adoption of my inventions by others more favoured, in relation to rendering steam-ships shot proof, beginning with the submerged screw shaft, in 1834, to the adoption of the curved in lieu of the radiating section of a screw, exhibited by me in 1851, and viewed then as a scheme, justify me in believing that the shell of shot-proof vessels must sooner or later be formed of plates of iron placed edgeways.

I am, your obedient servant,
George Beadon.

July 31, 1862.

P.S. In 1859 I consulted Sir Baldwin Walker, by letter, as to taking a secret patent, because I felt that its adoption by a foreign power would render our fleet comparatively useless. Had we gone to war with America, can anyone doubt that our line-of-battle ships would have been no match for Monitors or Merrimacs? My experience leads me to disbelieve all history. The Apostles generally reap the credit and reward of any benefit conferred on the community by an individual. G. B.

FORTIFICATIONS FOR GLASGOW.

Sir,—It is a very extraordinary thing, that after reading so many letters and speeches lately about forts and fortifications, that we Glasgow people never saw the unprotected state of our own town till this week. When I read your short description of Walker's new floating battery, and looked at the engraving, the whole thing flashed across my mind at once, that Dumbarton Castle, we had put so much faith in so long, had really become a thing of the past.

This is really and truly a fact — a vessel with a speed of twelve miles an hour would pass before a shot could be fired from the castle to do any damage.

Well, sir, seeing that clearly, would it not be wise policy for us to have a powerful battery constructed of our own, one with ten guns, at least; it might, for old associations, be called Dumbarton Castle; only let us be safe from evil-disposed persons, as you very properly call them.

Glasgow, no doubt, feels the blight that has fallen upon so many manufacturing towns, but still there is spirit enough left to take care of herself—it only wants a beginning; and you, sir, might give us a word of encouragement. I should like to see Glasgow take the lead in this as she did in steam-boats sixty years ago. We have the materials and the men; the Government would, perhaps, give us the guns; and so ultimately the Clyde would stand A 1 amongst the rivers of the earth.

We remain, sir, yours respectfully,
Foster & Co.

Glasgow, August 1, 1862.

Gossip.

At the annual dinner of Messrs. Worssam's employés, at the King's Arms Hotel, Hampton, last week, Mr. Worssam, in responding to his health, said there had appeared, in a recent number of the *Engineer*, under the head of "Wood-working Machinery," an article which, although he had before given that journal credit for impartiality in representing the merits of inventions and improvements, he could not place within the range of that category. The writer displayed but a very limited knowledge of wood-cutting machines, since he only dated from the year 1850, and he (Mr. Worssam) imagined that his knowledge had grown with the growth of Messrs. Robinson's, and dated from the time that they first thought of making wood-working machines. The fact, however, was that Messrs. Powis and James had exhibited a superior machine; Messrs. M'Dowall had a first class machine for the same purpose and for planing; and Messrs. Forrest and Barr, as well as themselves, had others.

The problem of drawing aluminium into wire has been resolved by M. Garapou, of Paris, an artizan, who now conducts the operation in a truly workman-like manner. He furnishes the aluminium wire at from 60 to 100 per cent. cheaper than silver wire of the same length. The price of aluminium is always about 200 francs per kilogram. For the purpose of drawing it into wire they commence with rods of aluminium of one mètre in length and twelve millimètres diameter — these the inventor easily reduces to wires of the size of a hair, and many hundred kilomètres in length. These products appear in the International Exhibition, where are exhibited articles of lace work, such as epaulettes, embroideries, textile fabrics, entire head-dresses, with mounting and ornaments constructed entirely of aluminium. These articles are remarkable for their lightness, and they show that a novel manufacture has been created by the new process of drawing aluminium into very fine wire.

The report of the directors of the Electric and International Telegraph Company states that the gross revenue for the last six months amounts to 102,367*l.*, against 102,519*l.* in the corresponding period of 1861. The working expenses present few marked features. The maintenance charge is somewhat less, but may probably be proportionately increased during the current half-year. One considerable item—viz., that for law and parliamentary expenses—appears in the balance sheet. The board consider it right to charge the whole of the expenses of the late contest with the United Kingdom Telegraph Company against the revenue of the half-year, and no debt on this account will remain on the company's books. Deducting from the gross revenue of 102,367*l.* the working charges and interest amounting to 71,131*l.*, which includes the exceptional item of 6,056*l.* alluded to, there is a clear profit of 31,236*l.* on the operations of the six months, and the directors are consequently enabled to maintain the usual dividend of 3*l.* 10*s.* per cent. for the half year, which will absorb 29,816*l.*, leaving a balance of 1,420*l.* to be added to the account for the renewal of the submarine cables. It is mentioned in the report that in order to pay for various extensions, the last instalment on the new shares will be immediately called up.

In the House of Commons, on Wednesday (week) Mr. Lowe, in reply to Mr. Jones, said that the greatest pains were taken that the ventilation of the schools which were assisted by the Government should be attended to, and there was no reason to believe that such ventilation was in a defective state. As to the process of Mr. Cooke, of Spring-gardens, which had been applied to the Colonnade Institution, Clare-market, he (Mr. Lowe) did not know what it was, but the educational department were always happy to hear suggestions on the subject.

The directors of the Algerian Cotton, Land, and Irrigation Company, which is established under the protection and support of the French Government, have received a copy of the concession from the Governor-General of Algeria. Its terms are more favourable than those published in the original prospectus, inasmuch as they confer a right to the water as well as to the land in perpetuity, while all the other valuable privileges previously conceded are confirmed.

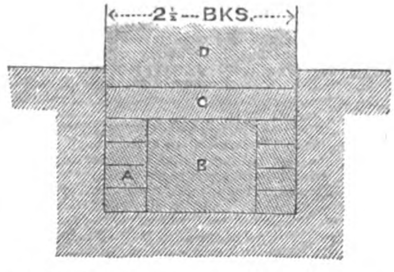
As the Town Councillors of Liverpool were assembling on Wednesday, at 11 o'clock, a man who was passing by at the moment, carrying a large jar, by some unexplained accident let it drop on the footpath. The jar was shivered, the man ran away in shame, and the Councillors, who were to consider that morning the grievances which had been made to them of the effluvium of petroleum, were disgusted with the suffocating odour which was emitted from the broken jar. It is said that the intelligence spread. The previously assembled Councillors rushed out to satisfy themselves. To judge by the sudden application of the manual digits of the Councillors to their nasal organs, the demonstration, though forcible, was anything but satisfactory; and each one was unexpectedly furnished — of course, by accident — with a practical knowledge of the scent peculiar to petroleum.

The first part of a catalogue of the Mediæval, Renaissance, and Recent Periods of works of art, on loan, at the South Kensington Museum, has just been published. J. C. Robinson, Esq., F.S.A., the superintendent of the Fine Art collections of the South Kensington Museum, is the editor, and has been ably assisted by Mr. R. H. S. Smith and the Rev. James Beck. This first part (published at one shilling) contains a catalogue of the sculptures in marble and terra cotta, &c., carvings in ivory, art bronzes, furniture, objects of ancient Irish and Anglo-Saxon art, various works of mediæval art, ecclesiastical utensils, &c., and "Henri Deux" ware. We may state that the exhibition of these works of art will be kept open to October.

In the year 1854 a scourge appeared which has several times threatened to destroy one of the great industries of France — the silk culture — which alone yields 300,000,000 fr. per ann. The Society of Acclimation of France undertook to examine the cause of this disease among the silkworms, and it appears that they have found that it is principally caused by a disease of the mulberry trees, on the leaves of which the silkworm is fed. They state that this disease can be cured by placing the infected eggs for some time in a box containing a little spirits of turpentine; but this treatment does not prevent the reappearance of the disease upon the worms when they are fed upon the leaves of diseased mulberry trees.

By using coal oil, instead of boiled tar, in preparing ropes, the risk from fire is greatly diminished.

On pulling down the extensive ruins of Messrs. Knight's soap factory, London-house Yard (destroyed by fire last year), one of the foundations was found to have been built as per sketch annexed. The wall was



A Half-back leaves. B Mould filled in.
C Stones every 3 feet. D Wall 2½ backs thick.

2½ bricks in thickness, and carried up to a height of upwards of 50ft. What would the Metropolitan Board of Works say to such *now?* First came two half-brick *leaves*, 4 courses high, filled in between with *mould*; on that, at *intervals only*, were laid small blocks of stone, partly moulded, and evidently the remains of some former building; on these, and on the mould where stone was absent, was built the massive wall that has stood so long without any sign of a settlement or of decay. The object for which this peculiar style of foundation was adopted is, of course, a mystery.

Outfit of Ships.—We have over and over again contended that the most important part of a ship's outfit rests in her pumps, although it seems hard to carry this opinion home to conviction, though facts daily recorded in our columns show that we hold no fallacious views on the subject. The most vital part of a vessel is her liability to sudden and dangerous leaks, and these calamities, as compared with others incidental to the sea, seem as six to twelve. A ship in nine cases out of a dozen may weather a gale provided she keeps free from leaks or has an efficient pump to grapple with any leak she may spring; but in ten out of twelve cases, if a vessel springs a leak at sea, and is fitted with an inefficient pump, she is sure to founder. Of the importance of efficient pumps, the presentation to Captain Boag, on Friday last, was sufficiently conclusive. The Uncas, shortly after leaving Bombay, sprang a serious leak at sea—a leak, in fact, which, had she not been furnished with a common pump, would have necessitated and warranted her abandonment. Captain Boag, however, knowing that his vessel was furnished with a pump equal to any emergency, clung to the Uncas, and brought her safely to Liverpool—in a word, the pumps saved both ship and cargo from total loss. Here is a strong illustration of the point we have long been urging, for there is little doubt had not the Uncas been furnished with Messrs. Payne & Formby's powerful pumps she would inevitably have foundered. We repeat, such a fact as the above proves that in no part of a ship's outfit is there anything of more importance than a powerful and efficient pump—one, in fact, to be relied upon in any emergency—and we think it does not require a great amount of logic to prove that by the general adoption of such a pump as Payne & Formby's (Winstanley & Kelly's patent), an immense amount of saving might be secured to the commerce of the United Kingdom.—*Liverpool Mercury.*

The prospectus has been issued of the Buenos Ayres Great Southern Railway Company. With a commanding direction, this undertaking offers great advantages for the employment of capital, as the Buenos Ayres Government guarantee 7 per cent. for forty years, while 6 per cent. will be paid during construction. The proposed capital is 750,000*l.* in 20*l.* shares. The line runs from Buenos Ayres to Chascomus, a distance of about seventy-five miles. An enormous traffic is certain, from which a large surplus over the guarantee is likely to be secured. The line will be constructed by Messrs. Peto & Betts. The grant of the railway is in perpetuity, but the Government reserve the right of purchasing it at 20 per cent. premium.

A prospectus has been issued of the Parlogwyn Tin Mining Company, with a capital of 25,000*l.*, in shares of 2*l.* 10*s.* The object is to work a mine at St. Stephen's, near St. Austell, Cornwall, which is to be purchased for 3,750*l.*, partly in shares.

A railway has been constructed in New Zealand fourteen miles in length, which rises in that distance 2,800 feet, or one foot in nineteen.

We have more than once called attention to the Inventors' Institute, and we are glad to find that it is now in working order. Sir David Brewster is the president, and the council consist of Admiral Sir Edward Belcher, vice-president; The Right Hon. the Earl of Caithness, vice-president; the Hon. Algernon Egerton, M.P., vice-president; Lord Richard Grosvenor, M.P., vice-president; General the Hon. James Lindsay, M.P., vice-president; His Grace the Duke of Manchester, vice-president; Robert Richardson, Esq., C.E., vice-president; Sir William Scott, Bart., M.P., vice-president; Sir John Villiers Shelley, Bart., M.P., vice-president; Henry Brinsley Sheridan, Esq., M.P., vice-president; Sir William Worsley, Bart., M.A., vice-president; James Jones Aston, Esq.; James Bancks, Esq.; W. H. Barlow, Esq., C.E., F.R.S.; Joseph Beattie, Esq., C.E.; Charles de Bergue, Esq.; Henry Bessemer, Esq.; The Hon. Slingsby Bethell; George H. Bovill, Esq.; Benjamin Burleigh, Esq.; John P. Clover, Esq., M.A.; Samuel Courtauld, Esq.; W. Dundas Gardiner, Esq., M.A.; James Glashier, Esq., F.R.S., F.R.A.S.; Robert Griffiths, Esq.; Dr. P. W. Latham, M.A.; J. E. MacConnell, Esq., C.E.; Walter Macfarlane, Esq.; John Milnes, Esq.; W. W. Moore, Esq.; Francis Morton, Esq.; Dr. Normandy; P. M. Parsons, Esq.; Fred. Ransome, Esq.; C. William Siemens, Esq., F.R.S.; Hume Williams, Esq. Hon. Solicitors:—Messrs. Lyne & Farington. Hon. Secretary:—R. Marsden Latham, Esq. The temporary offices of the Institution are at 26 Great George Street, Westminster.

A correspondent asks how it happens that all the shield ships on Captain Coles's principle, exhibited in the International Exhibition, have docks like the Royal Sovereign, which are now found to be wrong? He wants to know whether the Admiralty has acted unfairly, or whether Captain Coles is aware of the fact.

The *Akhbar* of Algiers announces, in its number of the 28th ult., that of the railways now in course of construction by Messrs. Peto and Betts, the section from Algiers to Blidah will be opened for traffic on the 15th inst.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

Steam Engines, &c., 153, 164, 167, 178, 202.

Boilers and their Furnaces, &c., 181, 196.

Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 159, 182, 186.

Ships and Boats, including their fittings, 185, 205.

Cultivation of the Soil, including agricultural and horticultural implements and machines, 160, 172, 190, 191, 201.

Food and Beverages, including apparatus for preparing food for men and animals, 168, 174.

Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 157, 177, 197.

Buildings and Building Materials, including sewers, drain-pipes, brick and tile machines, &c. *None.*

Lighting, Heating, and Ventilating, 193, 207.

Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 162, 166, 169, 171, 175, 189, 195, 198, 200, 206.

Metals, including apparatus for their manufacture. *None.*

Chemistry and Photography, &c., 204.

Electrical Apparatus, &c., 161, 188, 194.

Warfare, &c., 183, 187, 192.

Letter-Press Printing, &c., 165.

Miscellaneous, 154, 155, 156, 158, 163, 170, 173, 176, 179, 180, 184, 199, 203, 208.

---

153. C. Binks. *Improvements in generating steam, in superheating steam, and in apparatus employed therein.* Dated Jan. 21, 1862.

This consists in the direct application (and in the methods of effecting this application) to water for its vaporisation or conversion into steam—when such steam is to be generated in close vessels or boilers for its application as motive power and other uses—of the products of the combustion in atmospheric air of carbonaceous fuel, viz., the gaseous and volatile products of such combustion consisting chiefly of carbonic acid or carbonic oxide, or of both (according to the relative proportions used of the air and fuel) along with the nitrogen

of the air, and whilst the products are at or about the high temperature evolved on combustion. The invention also consists in heating (and in the method of effecting such heating) water for its vaporisation or conversion into steam by means of the direct application to it of the heat developed by the combustion of certain gases, when this combustion is made to take place whilst in actual contact with the water, and thereby made to impart to it directly the heat evolved in the act of combustion. Also in effecting the vaporisation of the water by the direct application to it of the heat evolved on the combination of the said gases, when such combination is made to take place separately from or out of immediate contact with the water, but whilst in proximate contact with it, and under such conditions that the products of combustion shall in their highly-heated state be applied directly to the water. Also in the use of superheated steam as the heat-giving agent for effecting the conversion of water into steam, such superheated steam being applied directly to the water to be vaporised. Also in effecting the conversion of water into steam by first producing the two gases, oxygen and hydrogen, within and from a portion of the mass of the water itself that is intended to be vaporised, and thus by effecting, whilst they are in actual or proximate contact with the water, the combustion or re-combination of such gases with the consequent reformation of water from them, and the evolution of the high temperature that follows or accompanies that combination. *Patent completed.*

154. J. Bate. *Improvements in machines for corking or stopping the mouths of bottles, jars, or any vessels requiring to be stopped up air-tight.* Dated Jan. 21, 1862.

This consists in securing a vertical metal frame to a substantial bed of wood or iron, the said frame having at the top a horizontal bearer, in the centre of which is a worm, which a screw works, and to which motion is given by a weighted lever or fly wheel being upon a centre; at the bottom of the screw is attached a movable bearer, and which rises and falls with the screw underneath, and to which are affixed the plugs which drive the corks of stoppers through gauged sockets (which are fixed in another stationary bearer) into the mouths or necks of the bottles, jars, or other vessels requiring to be stopped. *Patent abandoned.*

155. H. B. Barlow. *Improvements in machinery or apparatus for counting and indicating the number of revolutions of shafts or other articles, and for exerting power.* (A communication.) Dated Jan. 21, 1862.

This consists in various arrangements of compound differential motions for the purpose of reducing or increasing the speed of any given shaft in any given proportion, but principally for obtaining a very slow motion, and in applying the same either for the exertion of great power or for counting and indicating the number of revolutions which the shaft, moving with the greater velocity, is making in any space of time. *Patent completed.*

156. C. T. Bousfield. *Improvements in machinery for making nails and spikes.* (A communication.) Dated Jan. 21, 1862.

This relates to a novel arrangement of parts, constituting an improved nail-making machine, in which two pairs of compressing rollers are used for tapering the ends of the metal rods fed into the machine to a suitable shape for forming nails or spikes, in combination with a cutter for severing such tapered ends from the rods, and a heading die for striking up the heads of the nails or spikes while the same are held firmly between nipping dies, the object being to effect in a rapid and economical manner the conversion of rods or bars of iron or other suitable material into nails or spikes. *Patent completed.*

157. J. H. Rawlins. *Improvements in machinery used in the manufacture of paper.* (A communication.) Dated Jan. 21, 1862.

This consists in applying to a paper-making machine, wherein an endless web or woven wire is used, an apparatus consisting of a roller and travelling blanket or felt to remove the wet web of pulp from the endless web of wire of such machine. By these means the web of wet pulp is caused to adhere to the travelling blanket or felt, and the two together are pressed between pressing rollers, and then the web of pressed pulp or paper is separate from the blanket and passes away to be dried, while the travelling blanket returns to the paper-making machine. *Patent completed.*

158. A. J. Martin. *Improvements in the treatment of fusel oil, and for various applications of the same to useful purposes.* Dated Jan. 21, 1862.

The patentee claims, 1, the combination and treatment or preparation of fusil oil with pitch or other hydro-carbons as described, for the manufacture of an oil or fluid to be used for illuminating purposes. 2, treating fusil oil by subjecting it to the action of heated iron and steam as and for the purposes described. *Patent completed.*

159. R. A. Brooman. *Improvements in street and road sweeping machines, parts of which are applicable to the separation of liquid from solid substances.* (A communication.) Dated Jan. 21, 1862.

This invention consists, 1, in the employment in machines for sweeping streets and roads of two side brooms for drawing the mud and dirt into the path of the chain of brooms by which it is to be raised into a receiver. 2, in the particular construction and arrangement of the chain for carrying the brooms. 3, in the means afforded for raising the whole sweeping apparatus off the ground. 4, in the method of attaching the sweeping machine to the receiver for collecting the material swept up. 5, in the particular construction of the receiver to fit it for separating the heavy from the more liquid material swept up, so that the liquid may, in case of need, be used for watering the streets or roads. The details of the invention are voluminous.

160. W. Burgess. *Improvements in reaping and mowing machines.* Dated Jan. 21, 1862.

This refers to those machines in which the frame is supported on two wheels, and consists in dividing the second motion spindle into two parts united in a casting formed on or in a piece with the bevel wheel which drives the bevel pinion on the crank shaft or otherwise. Upon one part of the spindle the patentee keys a ratchet wheel, and fits ratchets or pauls upon arms cast on or formed in a piece with the said bevel wheel. He keys or fixes another ratchet wheel upon the other part of the spindle, and fixes ratchets or pauls upon the opposite side of the said bevel wheel to that which carries the teeth. Instead of the ratchets or pauls being fixed on and to the bevel wheel the ratchets may be fixed to it, and the ratchets or pauls may be carried on discs or projections fast on the parts of the spindle. The object of these arrangements is to allow of the machine turning without any of the working parts being stopped, for if one of the wheels travels faster than the other it turns with that portion of the spindle to which the pinion driven by it is keyed or fixed without affecting the motion of the other wheel or that part of the spindle to which the pinion driven by that wheel is keyed or fixed. By the arrangement before described the ratchet wheels and pauls are protected from dirt, and the bearings for the second motion spindle may be placed closer to the pinions driven by the main wheels than in any arrangements before proposed, and he is enabled to adopt the ordinary means for throwing the knife in and out of gear. *Patent completed.*

161. M. Henry. *Improvements in the mode of, and apparatus for, applying electricity to horology.* (A communication.) Dated Jan. 21, 1862.

This consists in regulating clocks by electricity, the clocks being so arranged and combined that they shall always gain or be a little too fast till the period of regulating them has arrived, and that when that period has come round they shall stop for a short interval to await the regulating current, which will allow them to go on again at the exact time. *Patent completed.*

163. S. Martin. *Improvements in the treatment of mineral oils, and in the apparatus connected therewith.* Dated Jan. 22, 1862.

One part of this invention, by which the patentee rectifies and deodorises the mineral oils usually called petroleum, herosine, rock oils, or oils the products of schistes or coals, peat, asphalte, or wood, consists in the use of caustic soda, mixed and agitated with the crude material, to which he subsequently adds a small quantity of tepid water. The details for carrying out this invention in all its branches are too voluminous to be quoted here. *Patent completed.*

164. J. Roberts. *Improvements in combined hydraulic motive-power engines and meters.* Dated Jan. 22, 1862.

This invention relates to the class of rotatory engines and meters where the cylinder is stationary and the piston, main shaft, and radial wings or arms rotate, the said wings or arms receiving the direct pressure of the water. The cylinder rests on framework in a horizontal position, and on the side thereof the patentee forms the inlet and outlet ports between which there is an abutment projecting inwards from the inner periphery or internal surface of the cylinder, the said ports being controlled, if desired, by slide valves or other cut-off gear. The piston is also cylindrical, but less in diameter than the stationary cylinder, and has two or more longitudinal slits or openings therein for the radial wings or arms, and a boss or other arrangement for securing it (the piston) to the main shaft, which latter rests on bearings in or near to the cylinder ends. Within and encircled by the piston and surrounding the main shaft is an eccentric-shaped cam made fast by keys or otherwise to the cylinder's end or cover. This cam, with the assistance of fitting pieces eccentric to the axis, guides the wings or arms which move through the slots in the piston over the abutment above referred to, one end or edge of the said wings or arms bearing on the cam and the other against the cylinder, the contact being maintained by springs fitted in the wings. For measuring and indicating the quantity of water or other liquid passed through the combined engine and meter, it is simply necessary to place on the main shaft or any other working part suitable for that purpose, pinions with worm wheel and multiplying arrangements of wheels and pinions, or catch and ratchet wheel, or any other apparatus for transmitting and recording motion with indices easily read, many modifications of which are well known. *Patent completed.*

165. F. W. Gerish. *Improvements in printing presses.* Dated Jan. 22, 1862.

Here the reciprocating bed or table on which the form of type is placed is caused to receive its motion from a rotatory axis or driving shaft, on which there is a crank which carries a pinion on the crank pin; the pinion rotates freely on the crank pin, and the teeth of the affixed wheel, which, by preference, is formed with internal teeth, and provision is made for the reciprocating bed or table which carries the type coming to rest at the time the impression is taken, notwithstanding the driving shaft continues its rotatory motion; and in place of the platen rising and falling to give the impression, the table with the type is lifted against a fixed stationary platen by cams. The press may be arranged to be worked by manual or other power. *Patent completed.*

166. E. Pace. *Improvements in laths for Venetian blinds, in painting such laths, and in raising and lowering Venetian blinds.* Dated Jan. 22, 1862.

The patentee claims: 1. The manufacture of laths for Venetian blinds by a slicing knife as described. 2. The construction of laths for Venetian blinds by gluing or cementing together two or more leaves or thicknesses of wood sliced or cut out of the plank as described. 3. Painting the laths by a roller or rollers in manner described. 4. Raising and lowering blinds by a roller fitted with a ferrule, in which is inserted a divided spring plug, substantially as described. *Patent completed.*

167. A. J. Beer. *Improvements in the valves of steam and other motive engines.* Dated Jan. 22, 1862.

This invention has for its object to take off or reduce the pressure upon the slide valves of steam or other engines, and thereby to reduce the friction and wear and tear of the parts. The invention consists in constructing on the valve a shallow cylinder open at both ends; outside this shallow cylinder another shallow cylinder or ring works steam tight, and is by suitable springs kept against the inside of the cover or the sustaining plate. This internal cylinder is provided with suitable packing and may be considered as an annular piston. Steam is supplied to the valve chest from the boiler, and when the induction ports are uncovered by the valve, the steam will enter the working cylinder; when the reverse action takes place, the steam will issue from the cylinder, and pass through the valve to the eduction passage. Owing to the peculiar construction of the valve there will be little or no back pressure, as the elastic force of the induction steam will be exerted against the fixed valve cover or sustaining plate, and not against the back of the valve, as is usually the case, as the back of the valve is dispensed with; the valve is mounted or secured in a band or plate to which the valve stem is secured. This latter passes through a stuffing box attached to the valve chest, and is worked in the ordinary way by eccentrics or otherwise. If two sets of valves belonging to separate cylinders are required to be worked in connection with each other, the double set of valves may be adapted to the same valve chest, which may be divided by a longitudinal partition into two compartments. This longitudinal partition of the valve chest will serve as the cover or sustaining plate for both valves *Patent completed.*

168. T. Little and J. Little. *Improvements in apparatus for cooling coffee berries.* Dated Jan. 22, 1862.

This consists of a box, case, or other suitable receptacle in which is disposed a cylinder of wire work, or other reticulated material, mounted on a horizontal axle, on which it rotates, and its diameter occupies for the most part the depth of the box, and its length the entire width thereof. The box is furnished with a suitable lid for access to the cylinder, and the cylinder has a longitudinal slide, opening, or lid at which to introduce coffee, and to empty it out of the cylinder; at the one end of the box is disposed a fan-blowing machine, which introduces a blast of cold air, while the other end of the box may be of wire work, or otherwise open for the escape of air. The cylinder has projecting ledges in the interior, so that during its rotation the coffee is continually being raised by the ledges, and allowed to fall after attaining a certain height. The cylinder is rotated by a crank handle or otherwise on its axis; this again gives motion by toothed gear to an intermediate stud wheel, from which a band imparts a multiplied motion to the fan. A drawer is disposed at the lower part of the box into which the coffee is emptied from the cylinder when cooled; it is conducted into the drawer by inclined shoots. *Patent abandoned.*

169. J. Hinks and A. Dixon. *A new apparatus for warming and drying boots, shoes, or slippers, to be called a boot-warmer; which apparatus is also applicable for racking or storing boots, shoes, or slippers, for exhibition or otherwise.* Dated Jan. 23, 1862.

This consists of a frame made of wood, iron, zinc, brass, wire, wicker or basket-work, so constructed that the boots, shoes, &c., resting upon the body of the frame shall expose their uppers to the action of the fire; the boots, &c., are retained on the frame by a bow, rod, or other means. *Patent abandoned.*

170. J. A. Mays. *Improvements in envelopes and other wrappers.* Dated Jan. 23, 1862.

To prevent the tongues or flaps of envelopes from adhering to their enclosures, the inventor proposes to apply the cementing or adhesive material to the upper surface of the edges of the flaps, instead of to the under surface thereof, and to fasten the envelope by tucking the flaps (with the adhesive material applied thereto as described) under the other parts of the envelopes, by which arrangement the adhesive matter is prevented from coming in contact with the enclosure or contents of the envelopes. For making envelopes capable of being more expeditiously opened, and to prevent their being tampered with without detection, he proposes to make at a short distance from any of the sides thereof a line or lines, or rows of perforations therein, or make to a crease or fold, or creases or folds therein, so that when it is desired to open the envelope the portion thereof beyond the said perforations or creases may be easily torn off. *Patent abandoned.*

171. J. Tomlinson. *Improvements in washing machines.* Dated Jan. 23, 1862.

This consists of a suitably shaped water-tight vessel containing two discs of wood, or other material, mounted parallel to each other on independent axles or rocking shafts, attached by connecting rods to a double-cranked driving shaft, mounted parallel to the two rocking shafts. The discs have formed on or fitted to their inner faces brushes or strips of vulcanised india-rubber, or other suitable elastic material springing therefrom at a right angle or nearer so to the inner faces thereof; or brushes and the elastic strips may be used in combination on one or both discs. The cranks or levers on the rocking shafts are constructed with rather more than twice the throw of the cranks on the revolving shaft, which cranks, being formed in opposite directions, impart to the discs reciprocating motion in opposite directions, thereby producing a rubbing action on the clothes, &c., when placed between the discs, they being surrounded with water containing soap or other detergent. *Patent abandoned.*

172. J. Wallace. *Improvements in reaping machines.* Dated Jan. 23, 1862.

The object of this invention is to improve the cutting action of the knives. These knives are a series of angular-sided blades attached to a bar, to which a reciprocating motion is imparted, this motion causing the blades to work between or through and within a series of bent back or grooved figures, which are fixed to the machine; and the invention consists in causing each knife point to traverse at least one half farther at each stroke than the distance between two adjacent fingers. This end may be obtained by various proportions of the parts, provided the proportions are made to correspond. *Patent completed.*

173. F. W. Werner. *Apparatus for the destruction of vermin.* Dated Jan. 23, 1862.

This consists of a lower part or case of circular, oval, or other form, either furnished with feet and open at the bottom, or having perforations or openings around or in the bottom for the admission of air, or having both. Upon the stand is mounted a kettle or teapot-like vessel, having instead of a movable lid a screw plug for the purpose of filling it with water or other fluid. Close to the top part of this vessel is a nozzle piece or opening into which a jet piece of a suitable shape is screwed. A lamp for burning spirits, oil, &c., is placed below the bottom of the upper vessel and lighted ready for use. The upper vessel being partially filled with water, or other vaporisable liquid, the steam or vapour generated within the vessel is projected through the tapered nozzle or jet pipe with considerable force against the object in which the vermin are secreted. *Patent abandoned.*

174. W. H. Ropes. *Improvements in machinery or apparatus for cleaning coffee, rice, or any seed or grain having an outer hull and inner pellicle.* (A communication.) Dated Jan. 23, 1862.

This applies more especially to that class of machines wherein the cleaning of the grain is effected by the attrition of one kernel or seed or grain against another in a mortar or other suitable receiver or vessel, and consists: 1. In the use of a spiral or inclined bladed propeller or propellers on an archimedian screw attached to a vertical shaft, and rotating inside the vessel containing the grain or other substance. 2. In the use of a raised step or projecting boss formed on the bottom of the vessel containing the grain immediately beneath the propeller or screw for preventing the collection or clogging of grain under the shaft or boss of the propeller. 3. In the use of one or more revolving scoops, attached to a horizontal arm or arms on the vertical shaft, for facilitating the movement of the grain towards the centre of the vessel. 4. In making the mortar either wholly or partially of stone

and with a movable bottom. Lastly, in the use of a current or currents of air for cooling and cleaning the grain. *Patent completed.*

175. H. Owen. *Improvements in the manufacture of stockings and other articles of hosiery.* Dated Jan. 23, 1862.

This refers to a previous invention patented Jan. 24, 1859 (No. 222), and which invention consisted in the introduction and construction of selvage courses or seams across articles of hosiery, so that worn portions thereof might be cut away and removed wholly or in part, leaving the remaining portion secured from ravelling by a selvage. The present invention consists in the insertion in or at the time of the manufacture of such articles of hosiery at each selvage course or seam constructed for such purposes as before mentioned, of a course of thread either of silk, flax, worsted, &c., such thread passing through the loops forming the respective seams or selvages of the main portion of the article, and of the removable pieces, and being rendered elastic by being taken up in length in its course across the "wale," so as to stretch in common with the other courses of the material composing the article to be made. The thread thus inserted, although so incorporated with the other material as to form part of the article to which it is applied, can be withdrawn therefrom without disturbing the remainder of the fabric, the worn part being separated by such withdrawal without the risk of injury to the article which would attend the operation of cutting out the injured portions. *Patent completed.*

176. G. Rogers. *Improved mechanical arrangements for letting-off water or other liquids from baths, vessels, or cisterns.* Dated Jan. 23, 1862.

This consists in substituting for the ordinary spigot and faucet tap, or other tap, used to let off liquids from butts, &c., a pipe or duct inserted into the body of the same, angled so that an ordinary short spindle drop valve may be adapted to the same within the butts, &c.; and thus, by being within the butt, &c., and at the farthermost of the letting-off duct or tap, shall insure the whole of the same being kept empty, except during the action of letting off the liquid, thus avoiding the ill effects of frost and insuring a greater facility of action. *Patent abandoned.*

177. J. C. Johnson. *Improvements in the manufacture of twist lace in twist lace machines.* Dated Jan. 23, 1862.

The patentee claims the combining and arranging the parts of a twist lace machine, so that the fancy warp threads used in conjunction with coiling warp threads are caused to move in opposite directions when making crossings, and to rest during the swing of the carriages, either from the back combs to the front combs, or *vice versâ*. *Patent completed.*

178. A. Ripley. *Improvements in the construction of pistons.* Dated Jan. 23, 1862.

This consists in a peculiar method, whereby the rings forming the metallic packing of steam pistons are caused to expand and press against the sides of the cylinder, so as to render it steam tight. The piston is composed of the usual plates having the ordinary segmental rings; on each face of the piston is an orifice passing through the plate into the interior; passing through these orifices, and working steam tight in them, are two small spindles or studs, each of which terminates in a conical wedge, or its equivalent, which, in turn, fits into and works within a corresponding hollow cone or seat; this seat is formed in two parts, and each part is attached to a segment of the ring, so that when the exterior of the piston is acted upon by the steam in the cylinder, pressure from the same cause is given to the heads of the small studs, the inner conical ends of which force asunder the parts of the hollow conical seat. These parts being attached to the segments of the packing rings cause them to expand wider and press against the sides of the cylinder. *Patent completed.*

179. H. Yates. *Improvements in machinery for bending, repairing, or renewing defective or damaged parts of iron rails.* Dated Jan. 23, 1862.

According to this invention, a suitable bed frame table or block, two dies, shaped according to the form of rail to be operated upon, are arranged, both being movable, or one being fixed and the other movable. These dies or jams are for gripping or retaining the damaged or defective portions of the rail or bar while in a highly heated state, and reducing it by pressure to its original form, as well as for holding any portion of the rail or bar while the process of welding is carried on with a view to renew any part of the surface. *Patent abandoned.*

180. J. G. Service. *Improvements in machinery or apparatus for cutting and scoring pasteboard and other similar material.* Dated Jan. 23, 1862.

Under one modification this machine consists of a pair of open-end standards, in which are arranged the bearings of a pair of rollers. Motion is communicated to the lower roller either by hand or other power, and this roller carries to and fro a table, to which a reciprocating traverse is imparted. In this table are fitted the knives for cutting the pasteboard; these knives are made adjustable as regards height by screws contained within the body of the table, so that the knives may be adjusted either for cutting or scouring. *Patent abandoned.*

181. A. W. Williamson. *Improvements in tubulous boilers or steam generators.* Dated Jan. 24, 1862.

Here the inventor combines a number of tubes or vessels by welding, brazing, or otherwise firmly joining them together, so as to form a cellular sheet or leaf, the sides of which present a corrugated surface, the tubes or passages being parallel and side by side longitudinally. They may have lateral openings connecting them together in various places along their length, and each sheet or leaf has a tube or vessel at each end, having openings made therein for connecting the tubes or cellular passages therewith. The boiler or steam generator is formed by combining together several of these tubulous or cellular sheets or leaves, with a space between each forming passages for the escape of the heated products of combustion. *Patent abandoned.*

182. J. Higgin. *Improvements in machinery for retarding and stopping railway carriages.* Dated Jan 24, 1862.

This relates to apparatus for retarding and stopping railway carriages by allowing them to descend and rest upon the skids or brakes which slide on the rails, and are held in proper position by suitable projections or flanges. The axles, wheels, bearings, and springs, as at present in use for carriages of the ordinary construction, may be used with slight modifications of some of the parts. An eccentric, or other equivalent, is used for lowering and raising the carriage, and instead of being placed immediately above the axle box, it is placed so as to act on one end of the spring, which is provided with a shoe with antifriction rollers to reduce the friction; and, if requisite, with clips taking projections on the eccentric to retain the parts in their proper positions. The lower plates for the bearings require to be made long so as to provide for the amount of lift required. In this arrangement, when the carriage is lowered to bring the skids or brakes on to the rails, the springs assume a diagonal position; and when the carriage is raised they are horizontal, as usual, each spring being joined at one end to a bracket of the usual construction. *Patent completed.*

183. J. Cornforth and B. Smith. *New or improved machinery for boring or drilling gun-barrels and tubes, and other articles having a cylindrical or prismatic figure, which said machinery may also be applied to other like articles.* Dated Jan. 24, 1862.

This invention is not described apart from the drawings. *Patent completed.*

184. W. Clark. *Improvements in the manufacture of artificial flowers, leaves, and fruit.* (A communication.) Dated Jan. 24, 1862.

The patentee claims, first, the manufacture of fruit and flowers of two tissues of a suitable nature, between which is interposed a thickness of flexible light, elastic, plastic, and resistant materials, the whole being suitably shaped and goffered, and afterwards dipped in fatty matters to give them a transparent appearance. Second, the use of a flexible and transparent matter, such as violin strings, for mounting flowers, fruit, &c., instead of the metallic wire in ordinary use. *Patent completed.*

185. J. Longhurst. *Improvements in chains and chain cables.* Dated Jan. 24, 1862.

This invention is not described apart from the drawings. *Patent completed.*

186. J. Rock. *Improvements in common road carriages.* Dated Jan. 24, 1862.

This invention consists, 1, in making a carriage with a movable, close, or coach-head, interchangeable with two half-heads, similar to those of a landau. The inventor makes the coach-head in the same way as that of the "diorópha" carriage, patented by him Nov. 9, 1850, No. 43,328; and the landau half-heads he constructs in the same way as the barouche head of the "dioropha," so far as regards the framing, strengthening, and fastening of the parts which meet and rest upon the lower body of the carriage at the elbow line. 2. In addition to the coach-head and the landau heads, he sometimes makes a third head of the kind usually made to a barouche, which head may be used in lieu of the other two; and he also makes a folding flap, or flaps, to the body, to the front seat, and doorway, also in the same way as a barouche. These barouche fittings and head may be used interchangeably with the landau heads, in cases where the carriage is not fitted with a coach-head also. 3. In some cases he uses the hinder half of the landau head in conjunction with the flap. When he so uses the half landau head, he sometimes adds a movable side piece, which may be either of panel, leather, or glass, in suitable framing, and which may be also made to turn back on hinges or joints, and serve as a wing or mud-guard. 4. In order to give more light to the interior of the landau head, he makes side lights in some or all of the four "quarters." These side lights he makes with or without detached frames, either hinged to the head or made movable, and he places them when removed in recesses formed for the purpose in the doors, or some other part of the lower body. These side lights may be of any suitable shape, and the frames may be provided with glass, venetian slats, or panelling of any kind. 5. In order to avoid the notch which usually appears in a landau head at the junction of the standing pillar when thrown open, he makes the standing pillar with a projection, and cuts away a corresponding portion of the door pillar. He then carries the pillar joint as near as possible to the inner edge of the door pillar, and he makes such pillar joint with a knuckle, the whole breadth of the pillar, and sufficiently large to allow of the groove necessary for the glass frame or blind to work in, to be filed or otherwise cut out of it, without cutting into the rivet or centre pin; or he makes the joint only of the breadth of the groove or grooves, and carries the pillar down at each side of it to form the rebates which confine the glass or blind; he strengthens these portions of the pillar, which must necessarily be thin, with metal if required. 6. This invention relates to the foundation of the various parts of carriages called transom beds, spring beds, horn bars, futchels, splinter bars, pump handles, perches, and axletree beds of plate iron or steel, cut out or forged to such shapes as, when bent to enclose or partly enclose a hollow, will form such beds and other parts of the usual or any required shape, with some parts larger than others as necessary for use as bearings and otherwise, or for symmetry. *Patent abandoned.*

187. J. W. Girdlestone. *Improvements in projectiles for fire-arms.* Dated Jan. 24, 1862.

This consists in encasing the rear portion and part of the sides of the shot or projectile with a jacket of wood, papier mâché, or other suitable material. The outside of this casing or jacket fits the bore of the gun whilst the inside fits the shot, and provision being made for enabling the jacket to detach itself readily from the shot so soon as it leaves the gun. In the case of rifled guns, the twist that is imparted to the jacket is transmitted therefrom to the projectile by a square or other suitably shaped recess in the rear of the jacket being driven over a corresponding projection on the projectile by the explosion of the charge, the projectile on loading being not quite driven home in its jacket. *Patent abandoned.*

188. T. Morris, R. Weare, and C. H. C. Moncktons. *Improvements in submarine and other telegraphic communication, and in apparatus connected therewith.* Dated Jan. 24, 1862.

This consists in the application of electric light, however generated, to the purpose of producing signals and communicating intelligence. The apparatus consists of one or more vacuum tubes or vessels of glass, or other material, or combination of materials, variously shaped and coloured or not. *Patent completed.*

189. C. G. Hall. *Improvements in the manufacture of boots, shoes, and leggings.* Dated Jan. 24, 1862.

This consists in the manufacture of boots, shoes, or leggings, or parts thereof, of horse hair, goats' hair, human, or other suitable hair, with which may be mixed silk, wool, cotton, flax, or other suitable animal or vegetable textile or fibrous material. *Patent completed.*

190. A. Wallis and C. Haslem. *Improvements in thrashing machines.* Dated Jan. 24, 1862.

This consists in a peculiar arrangement of apparatus for raising the grain from the hopper or compartment of a thrashing machine, which receives the grain from the winnowing portion of the machine to a screen or compartment of the thrashing machine, from which it is to be delivered into sacks or otherwise. For these purposes a shoot is used, the lower end of which descends into the hopper chamber, or compartment where the grain is received after being screened, and the upper end of the shoot rises to the position at or near where the grain is to be lifted to in the thrashing machine. This shoot is continually exhausted by a fan or other form of exhausting apparatus, the inventors preferring to employ for this purpose an ordinary fan, to the centre of which the upper end of the shoot is attached. The grain is continually raised by the rush of air from the outer atmosphere up the shoot to the exhausting apparatus, and it is delivered from the upper end of the shoot to a second winnowing apparatus. *Patent abandoned.*

191. J. Allison. *Improvements in apparatus for tilling land by steam power.* Dated Jan. 24, 1862.

We cannot here give space to the voluminous details of this invention. *Patent completed.*

192. W. Baker. *Improvements in fire-arms.* Dated Jan. 25, 1862.

Here the stock is provided with a sliding piece, acted on by a spring, with one end adapted to stop the trigger, whilst the other end of this sliding piece projects sufficiently through the butt and plate to be pressed inwards when the butt and plate are resting against the person holding the gun in position for firing. To prevent the effect of pressure exerted upon this sliding piece being to release the trigger, except when the trigger is also acted upon for firing at the time of the gun being held in position for that purpose, there is a supplemental stop or holder which is released by the pressure of the hand whilst pulling the trigger. The combined stops being thus simultaneously operated upon, the trigger becomes free to release the hammer. *Patent abandoned.*

193. W. Johnston. *Improvements in lamps.* Dated Jan. 25, 1862.

This relates to lamps for illuminating shop windows, halls, stations, &c., and which are of the kind comprising a variety of jets or other lights, arranged star fashion, or otherwise; and the invention comprises various improvements in forming, constructing, shaping, or arranging the details of such lamps. *Patent abandoned.*

194. C. West. *Improvements in the insulating and covering wire, and in the preparation of the materials for insulating.* Dated Jan. 25, 1862.

Here the patentee uses only the very best South American rubber, not masticated, but in its natural state. He prepares the rubber by boiling it in water, or by steaming it after it has been cut into ribbons or strips from the bottle or block after boiling or steaming it. He then allows the moisture to evaporate, until the rubber is perfectly dry, and in this state he stores it until required for use. Previously to placing the rubber on the wire, he steeps it in warm water. The rubber so prepared will then be open to the action of the solution he purposes applying to it while placing it round the wire, which solution will consist of india rubber dissolved in benzine, or any of the other solvents of india rubber, or it will consist of the solvents themselves, either in combination or singly. He places a trough over the wire, through which he allows the solution to percolate on the wire or on the rubber, just as it enters the mandril, with a receiving dish underneath, to catch such of the solution as may fall from the passing wire. After passing through the mandril the wire or rubber that is thus saturated with the solution, receives the rubber to be wound upon it from the reel or bobbin as it revolves round it, and the tension at which the rubber is placed round the wire, at each revolution of the reel or bobbin, presses the solution through the interstices of the overlapping rubber, and thus unites it into one solid tube. *Patent completed.*

195. J. C. T. Mougin. *Improvements in bercceaunettes or cradles for children or for dolls.* Dated Jan. 25, 1862.

According to this invention, the top of the basket is fixed with iron or wooden plates to the bottom, to give it greater solidity than those with nets. The basket is suspended by the middle from posts underneath the cradle, or by the top upon steel plates, or by knobs which screw according to pleasure. To this cradle a clock movement is adapted, similar to a roasting-jack, but modified and disposed to the use of the cradle. *Patent completed.*

196. J. H. Johnston. *Improvements in the prevention or removal of incrustation in or from steam generators, and in the apparatus employed therein.* (A communication.) Dated Jan. 25, 1862.

This consists in the use of a peculiar liquid, which, when introduced into the boiler, prevents incrustation therein. The liquid is composed of eight parts, by weight, of potash of commerce, or carbonate of potash, and from two to eight parts, by weight, of molasses, added to one hundred parts, by weight, of small or slug liquor. The apparatus is not described apart from the drawings. *Patent completed.*

197. D. Edleston and H. Gledhill. *Improvements in means and apparatus for finishing textile and other fabrics.* Dated Jan. 25, 1862.

This consists in the use of the flames arising from the combustion of coke or cinder-coal, wood, or other combustible matter or material, so that fabrics may be passed over, and in contact therewith, whereby the singeing of fabrics is effected with great facility, and at a considerable reduction in the cost. *Patent completed.*

198. E. A. Curley. *Certain improvements in sewing-machines.* Dated Jan. 25, 1862.

This invention is not described apart from the drawings. *Patent completed.*

199. J. Wright. *Improvements in constructing works below water.* Dated Jan. 25, 1862.

This consists in forming continuous foundations for sea and river walls, or like structures under water, by the use of cylinders or coffers, in the constructing of coffer dams. *Patent completed.*

200. F. J. L. Lefort. *Improved mechanical arrangements constituting a secret and invisible safety lock, applicable to iron safes and other depositories.* Dated Jan. 25, 1862.

According to this invention it is proposed to render the uncovering of a letter lock more difficult, by the action of the letter lock to release an ornament attached to the safe. *Patent completed.*

201. F. and A. Roberts. *Improvements in apparatus for ploughing or cultivating land.* Dated Jan. 25, 1862.

This consists partly in a carrying frame or carriage

mounted on wheels, the frame being divided into two halves, each half being occupied by a movable frame, with its set-off ploughs, trench ploughs, or other implements. At certain points the carriage is provided with toothed racks, and, at corresponding points in the movable frame, mortices are forged, which slide up and down the toothed racks. By an arrangement of spindles, pinions, worm wheels, and worms actuated by a crank handle and the toothed racks, the movable frame, with its implements, is raised or lowered, the object being to enable the ploughman to raise one set out of its work and lower the other in at the turnings, and to allow him to regulate the depth of their penetration. The movable frame is furnished with cross bars and longitudinal beams, which slide on the cross bars for regulating the width of the furrows. To guide the apparatus, a wheel is fitted or keyed on the vertical stem of the copse that carries the travelling wheels and gearing; with this wheel is a worm, fixed to the end of a short spindle, which is turned by a steering wheel, or by lengthening the spindle, the implement may be steered from the other end. At the steering end there are two wheels, the larger one is to run in the furrow, the smaller on the land. *Patent abandoned.*

202. J. Brown and J. Davenport. *An improved lubricator for pistons.* Dated Jan. 25, 1862.

This consists of a lubricator having two thoroughfares open to the steam, with a direct communication through the tap or plug, which tap or plug may be placed in a horizontal or vertical direction. *Patent completed.*

203. A. Samuelson. *Improvements in hydraulic presses and in the mode of working the same.* Dated Jan. 25, 1862.

This invention consists in a peculiar combination and arrangement of pumping apparatus for hydraulic presses, whereby the patentee is enabled to work one double press by the aid of four pumps, producing a regular and intermittent action upon the rams of the presses operated upon, and thereby gaining a considerable saving of time and labour in such process. *Patent completed.*

204. W. Smith and C. Tiesset. *Improvements in the manufacture of colours for dyeing and printing.* Dated Jan. 27, 1862.

This consists in the application of an essential or volatile oil or liquid, produced by a distillation or preparation of oily, fatty, oleaginous, or saponaceous matters to the manufacture of colours for dyeing and printing. The essential or volatile oil thus produced, when acted upon by certain chemical reagents, forms an organic basis by which the requisite colours or shades of colour are produced. *Patent abandoned.*

205. J. Lillie. *The application of new materials to the bottoms of sea-going and other vessels for the prevention of fouling.* Dated Jan. 27, 1862.

The patentee claims, 1, covering the hulls of vessels with a sheathing of non-porous and enamelled tiles, constructed and applied as described. 2, covering or coating the hulls of vessels with Japanese wax, with or without any admixture, such as chalk, applied as described. 3, covering or coating the hulls of vessels with cement and wax in combination, as described. 4, covering or coating the hulls of vessels with a species of concrete and wax in combination, as described. Lastly, the use of strychnine, arsenic, or other poisonous substances, as described. *Patent completed.*

206. S. A. Carpenter. *An improvement or improvements in covering and combining strips or bands of steel for crinoline or crinoline skirts.* Dated Jan. 27, 1862.

This consists in covering and combining a series of two or more strips or bands of steel for crinoline and crinoline skirts by a fabric, into which the bands are woven parallel to each other, the fabric also separating the strips from one another. *Patent completed.*

207. R. Martindale. *Improvements in globes and glasses to be used with hydro-carbon lamps.* Dated Jan. 27, 1862.

By this invention the breakages arising from the chimney being fixed at the base so near to the flame will be avoided. The patentee takes a globe of the common moon shape, or other suitable shape, and suspends inside it from the top a glass perdifume, or bell-mouthed tube; or it may be formed in one piece with the globe. Another form of globe which will answer well, is made by shaping the globe into a flattened spheroid, and forming a neck rising out of the top of the globe, so that the glass presents the appearance of a peculiarly shaped bottle. Several modifications are given. *Patent completed*

208. C. W. Harrison. *Improvements in printing, stamping, embossing, perforating, and other like operations, and in the machinery or apparatus employed therein.* Dated Jan. 27, 1862.

According to this invention, the operating pressure or percussive force is obtained by the adoption of electro magnetic action, so as to secure an important saving in the labour and time ordinarily required. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated March 27, 1862.

845. J. D. Schneiter, Paris, geographer. An improved method for printing letters, numbers, musical or other characters or signs on maps, plans, sheets of music paper, or other similar impressions.

Dated April 26, 1862.

1226. T. U. Brocklehurst, Macclesfield, Cheshire, silk manufacturer. Improvements in machinery for reeling singles, trams, organzines, and sewing silks.

Dated May 2, 1862.

1300. C. F. Whitworth, Yorkshire, engineer. Improvements in apparatuses for signalling upon railways.

Dated May 21, 1862.

1530. J. Hopkinson, 235 Regent Street, London, pianoforte manufacturer. Improvements in pianofortes and in the hammer rails of pianofortes.

Dated June 14, 1862.

1771. J. F. Miguel, Tours, France, doctor. An improved pessary.

Dated June 21, 1862.

1827. B. Fabbricotti, 150 Leadenhall Street. A polishing and grinding belt, formed of leather or other flexible or pliable material, having plugs composed of emery or other gritty substance, and a proper cement inserted in it substantially. (A communication.)

Dated July 4, 1862.

1948. J. Howard and J. Bullough, Accrington, Lancashire, iron founders. Improvements in warping and beaming machines.

Dated July 5, 1862.

1954. P. B. O'Neill, Warwick Street, Regent Street, gentleman. Improvements in screw wrenches or spanners.

Dated July 7, 1862.

1955. J. Kidd, Cannon Row, Westminster, engineer. Improvements in gas meters.

Dated July 10, 1862.

1984. E. Jaudeau, 1 Guildford Road, Brighton. An improved method of, and apparatus for, removing the bad flavour from alcohols distilled from grain, beetroot, of other vegetables, and for extracting the whole of the alcohol contained in the fermented juice.

1988. J. Ponti, Venice, Austria. An improved apparatus for viewing photographic pictures, and the preparation of photographic pictures to be used in such apparatus. (A communication.)

Dated July 12, 1862.

2004. J. Abraham, Birmingham, machinist. Improvements in presses for raising or shaping metals.

Dated July 14, 1862.

2018. A. A. Gannal, Paris. Certain improvements in the manufacture of bituminous cement.

Dated July 16, 1862.

2042. R. Dunn. Improvements in furnaces for steam boilers and other purposes.

Dated July 17, 1862.

2044. J. Dickson, 66 Tollington Road, Holloway, Middlesex, gentleman. Improvements in the manufacture of caustic soda and carbonate of soda.

Dated July 18, 1862.

2054. J. R. Abbott, Birmingham, lamp manufacturer. Improvements in sliding chandeliers, gaseliers, and other pendent lamps.

Dated July 19, 1862.

2060. R. Barrett, Stepney, Middlesex, engineer. Improvements in apparatus for working the damper of steam-engine furnaces.

2062. A. Cotelle, France, distiller. Improvements in the manufacture of alcohol.

2064. W. E. Newton, Chancery Lane, Middlesex, civil engineer. Improvements in ordnance and projectiles for the same. (A communication.)

2066. T. H. Saunders, Phœnix Mills, Dartford, Kent, paper manufacturer, and J. Millbourn, manager. Improvements in the manufacture of paper.

Dated July 21, 1862.

2068. C. Ramsay, New Bond Street, Middlesex. An improved military cloak.

2072. T. Davey, Tuckingmill, Cornwall, gunpowder manufacturer. Improvements in the manufacture of gunpowder and explosive compounds.

2076. A. Phillips, Glasgow. Improvements in looms for weaving figured fabrics.

Dated July 22, 1862.

2078. S. Lord, machinist, and J. Lord, manager, Facit, near Rochdale. Improvements in carding engines.

2082. J. Daniels, Leigh, Lancashire, manure manufacturer. Certain improvements in artificial manure.

2084. W. E. Gedge, Wellington Street, Strand, Middlesex. An improved instrument for marking wadded or other stuffs. (A communication.)

2086. H. R. Summons, Navarino Terrace, Dalston Road, Middlesex. An improved apparatus for bordering envelopes, paper, and cards.

2088. T. King, Truman's Brewery, Spitalfields, Middlesex. Improvements in apparatus for measuring malt, grain, and other granular substances.

2090. J. H. Johnson, Lincoln's Inn Fields, Middlesex. Improvements in the treatment of the noxious gases or vapours produced in the distillation or purification of tar. (A communication.)

Dated July 23, 1862.

2094. Z. Colburn, Tavistock Street, Bedford Square, Middlesex, mechanical engineer. Improvements in apparatus for the condensation of steam in steam engines.

2098. E. Alcan, Coleman Street Buildings, London, merchant. Improvements in machines for combing and carding wool and other filamentous materials. (A communication.)

Dated July 24, 1862.

2102. J. Horton, New York, America. Improvements in breech-loading fire-arms.

2104. H. Rawson, Leicester, manufacturer, and F. Staples, Leicester, mechanic. Improvements in machinery for combing wool and other fibres.

2106. J. G. Clarke, Brackley, Northamptonshire. Improvements in scythes.

2108. W. Clark, Chancery Lane, Middlesex. Improvements in machinery for the manufacture of fishing and other nets. (A communication.)

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

2144. R. Thompson, Boston, America. A new and useful improvement in lockstitch sewing machines.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

775. A. Hill. Fastening for stays.
787. J. Fawcett. Scouring, cleansing, and fulling of woollen or other cloths.
804. T. F. Hale. Valves.
812. C. M. Roullier. Flat cables or chains.
814. J. Topham. Preventing incrustation in steam boilers.
816. W. Henson. Knitting machinery.
821. W. Beaumont. Sights for rifles.
831. J. H. Johnson. Apparatus for cleaning tubes and flues of steam boilers. (A communication.)
835. H. Nunn. Mangles.
848. R. Edwards. Machinery and apparatus for pulverising, stamping, and washing mineral, animal, and vegetable substances.
852. J. L. H. Clémence and V. de Corneillan, Comtesse de. Treating open cocoons, and converting the waste resulting therefrom into paper.
854. R. de Bary. Manufacture of cigars. (A communication.)
859. W. F. Smith and A. Coventry. Lathes and machines for turning and cutting screws.
860. G. H. Birkbeck. Producing imitation mosaics. (A communication.)
864. W. B. Nation. Manufacture of boxes.
865. R. A. Owen. Screw propellers.
875. I. Morris. Cultivating land.
880. W. Paterson. Manufacture of iodine.
882. J. Baker. Improved alimentary preparations.
884. J. Platt and W. Richardson. Carding engines.
892. W. H. Hook. Folding envelopes and paper.
906. P. R. Couchoud. Manufacturing chenille and other lace-work.
907. C. P. Gontard. Stopping piece for watches.
915. H. W. Caslon and G. Fagg. Casting printing types.
921. H. Lorenz and T. Vette. Filters.
925. S. Warren. Transmitting motion.
937. G. Rebour. Autographic log.
941. J. Newton. Construction of breakwaters, piers, and sea walls.
942. G. Hunter. For cutting, sawing, and planing stone, marble, and slate.
950. H. T. Hassall and M. Burke. Invalids' chairs.
982. W. Simons. Constructing ships or vessels.
987. T. Jackson. Pianofortes.
1019. R. Theyson. Cork-cutting machinery.
1044. J. F. Mathias. Pressing and ironing straw hats.
1052. J. Howard, E. T. Bousfield, and T. Phillips. Steam cultivation.
1218. A. C. Kirk. Refrigerating apparatus.
1237. A. Lester. Manufacture of the fronts or uppers of slippers, shoes, boots, and gaiters.
1646. J. Betteley. Ship building.
1668. J. J. H. Gebhardt. Fastening for bags. (A communication.)
1767. J. Lancelott. Manufacture of ornamental chains.
1833. J. Anderton. Tape-leg or sizing machine.
1890. I. Holden. Preparing and combing fibrous materials.
1952. C. G. Hill and W. Jackson. Producing ornamental patterns or figures on lace.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed August 1, 1862.

289. T. M. Meekins.
315. P. H. Astley and C. Leighton.

Note.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, AUGUST 15, 1862.

METROPOLITAN IMPROVEMENTS.

Having recently given a detailed description of the Metropolitan Main Drainage Works, we shall now give only a brief analysis of their nature, object, and extent. This great scheme consists of the construction of three main sewers on each side of the Thames, running east and west, and intercepting the sewage, which is conveyed by the present system in mains running north and south, and flows into the Thames. The entire drainage of the metropolis and of the immense area combined with it, instead of falling into and polluting the river, will be carried through the new mains along the banks of the Thames, and deposited in reservoirs thirteen miles below London. Here the sewage will be deodorised and discharged into the river at a proper height and flow of the tide for carrying it out to sea, and rendering the return of any portion of it back to the metropolis an impossibility. When the works are completed, the ebb and flow between the bridges of 300,000 gallons of putrescent fluid, which now daily contaminate the stream, will cease, and the once silvery Thames will be restored to its purity. The other evils of the present system will be removed. The miasma from the stagnation of sewage in the drains, engendering disease of the most virulent character, and the periodical flooding of low-lying districts by the mains being tide-locked, will altogether cease, and the health and cleanliness of the metropolis will be greatly increased. A few figures will give us an idea of the vast magnitude of the undertaking. The three gigantic main sewers on each side of the river will form a total length of fifty miles. The underground tunnels, which will extend from London to Barking on the north and to Erith on the south side, will be 9ft. and 10ft. in diameter, and are calculated for the conveyance of twice the amount of the present drainage. The main sewers are of three classes — high, middle, and low level — corresponding to the levels of the districts to be drained. At a little distance below London the sewage will be lifted from the lower to the higher level on each side of the river by 8 pumps of 7ft. diameter and 4ft. stroke, with engines of 500 horse-power, which will each daily raise 19,000,000 cubic feet of sewage from 19ft. below low water to the high level ducts, and will be capable of raising 25,000,000 cubic feet per day. From these ducts the sewage will descend on the north side by 3 tunnels, each 9ft. 6in. in diameter, and nearly 4 miles long, and on the south side by one tunnel 10ft. in diameter to the depositing reservoirs, which will cover 14 acres on the north and 5 acres on the south side. One continuous tunnel, which will pass under Woolwich, will be 1½ miles in length, and 80ft. under the surface of the ground. On the north side the high level main is completed and at work, the middle level is in a forward state, and Mr. Bazalgette, the engineer of the Board of Works, calculates that in a year and a half from this time all the main sewers will be constructed. Before all the works are completed, 800,000 yards of concrete and upwards of 300 millions of bricks will be used, and 4,000,000 cubic yards of earth will be removed. A plan is organised for the formation of a company to utilise the sewage as liquid manure on a large scale, so that the question as to its value will be determined.

The total cost of this grand work is estimated at 4,000,000*l.* sterling; and, before its completion, with the supplementary works, which it cannot fail to call into existence, will probably be increased to 6,000,000*l.* What an idea does not this give of the magnitude, grandeur, and wealth of a city which expends such vast sums on underground works for the comfort and health of its inhabitants!

The Metropolitan Subterranean Railway Works were inspected last week by a party of the directors and other gentlemen interested in the undertaking, who passed through the entire length of the line from the junction at Paddington to within a few yards of the temporary station at Farringdon Street. The inspection commenced at the terminal station at Paddington, the construction of which is a difficult piece of work, arising from the confined and awkward nature of the ground on which the station has to be fitted on either side of the up and down lines of the metropolitan branch. At this point an artificial roadway is carried on girders to give room for a standing, and for an approach for cabs and omnibuses. The engine used on Monday was especially designed for the line by Mr. Fowler, the engineer of the company. It consumes its own smoke and condenses its own steam, and gives off neither smoke nor vapour when it once enters the tunnel. The carriages are lighted with gas on a simple and efficacious plan. In an india-rubber bag, on the roof of each carriage, the gas is enclosed, and feeds two lamps for two or three hours. This arrangement has been at work for some time on many of our northern lines and on the continent, and has always worked with safety. When empty, the bags are replenished in a few moments from an ordinary gas-stand pipe. The train proceeded at the rate of about twelve miles an hour — a speed that was seldom exceeded, from the constant stoppages to visit all the stations. The tunnel was perfectly clear, free from close air, dry, and well lit. The directors were perfectly satisfied with the result of their inspection. The line, it is reported, will be open for traffic on the 1st of October.

The Report of the Commission for the Embankment of the Surrey Side of the Thames has lately been published. The commissioners were appointed to examine plans for embanking the Surrey side of the river within the metropolis, and to report which of the plans will conduce with the greatest efficacy and economy to the improvement, embellishment, and convenience of that part of the metropolis, improve the navigation of the river, and provide a public thoroughfare without stopping such trade as must be carried on upon the bank of the river, and also upon the cost and means of carrying the same into execution. Responding to an advertisement, twenty designs were submitted to the commissioners for examination, and a short description of each is appended to the report. The excellence of many of these plans, which embrace the banks of the Thames from Deptford to Battersea Park, is admitted; no one of them is recommended for adoption in its entirety, but the principal features of some are embodied in the scheme proposed by the commissioners. The proposals comprised three sections, namely, Deptford to Westminster Bridge, Westminster Bridge to Vauxhall Bridge, and thence to Battersea Park. The commissioners are of opinion there is no necessity for a public road from Deptford to Westminster Bridge. It would, they say, cause a vast expenditure of money, and great disturbance of the trade on the south side of the metropolis. They foresee, however, that the owners and occupiers of wharfs may wish to carry out a plan of embankment, and they recommend that every facility should be afforded for securing uniformity of design and navigation in the execution of the works, but not at the public expense.

In executing the second section, from Westminster Bridge to Vauxhall, a great improvement would be effected by an embankment and railway between those points. The frequent flooding of the low grounds on the Surrey side, which are the source of great distress and sickness, affecting the poorer classes, would be prevented, and that part of the metropolis would be greatly embellished. The third section, between Vauxhall Bridge and Battersea Park, is strongly recommended. An embanked roadway would afford access to the Battersea station of the South Coast Railway and to the goods station of the South-Western and Chatham and Dover Railway, would improve and embellish that part of the metropolis, and afford a convenient and agreeable approach to Battersea Park. The report proposes that an embanked roadway of about two miles in length should be formed from Westminster Bridge to Battersea Park, on a viaduct of ornamental character, opposite the Houses of Parliament as far as Bishops' Walk, and thence on a solid embankment to the new Suspension Bridge at Battersea. Dredging the fore-shore to a level of five feet below low water will improve the navigation, and the nature of the works would prevent the accumulation of mud. The estimated cost of the works, including land and compensation, is 1,000,000*l.* If the present opportunity is not embraced at once, the cost will be much greater, by reason of the increasing demand for land and houses. To meet the expense, the coal and wine dues would have to be appropriated for a *further period.*

The third great iron bridge, carrying the Charing Cross line over the Southwark Bridge Road, was commenced last week. Those over Stamford Street and Blackfriars Road are successfully completed. The works and foundations for that over the Borough to London Bridge are also progressing.

In connection with the approaches to the permanent Crystal Palace Exhibition at Paris, it is announced in the *Moniteur* that the foundation works of the bridges across the Seine between the Pont de Genalle and the Pont de Sevres have commenced. These bridges, of which several have been already built, are on the system of the engineer, M. Legrand, of which the merit is facility of construction and economy of expense. The bridge is formed of two massive girders, extending from shore to shore, which are twelve mètres apart, and tied together by means of a system of rigid lattice-work, supporting a platform of cast-iron plates, on which the roadway is laid. The iron-work will be fitted together piece by piece on the surface of the abutment pier on the right bank, and will be pushed forwards on to the supporting cylinders in the river gradually as the fitting of the iron-work progresses. This plan has been successfully practised with several iron bridges and viaducts, thereby avoiding the inconvenience of scaffoldings, which are indispensable in other systems of fixed bridges.

In Class No. 10 of the International Exhibition is exhibited a model of Mr. Asprey's plan for connecting the railways on both sides of the Thames, and relieving London Bridge of the traffic to and from the different railway stations. This plan embraces a line of railway

from the London Bridge to the Fenchurch Street station, crossing the Thames on the east side of London Bridge, with a branch on the south side to the Charing Cross Railway. The advantages of the plan are, that the through traffic would not require a change of carriages; passengers would be conveyed direct from the South-Eastern and South-Western and West End Railway direct to the city, and right through to the Blackwall and other lines in connection, and London Bridge would be relieved of an immense amount of traffic.

THE COINAGE OF 1861.

As some very meagre and incomplete statements have gone the round of the general newspapers, in reference to the quantity of coin of each denomination issued from the Royal Mint in the year 1861, we deem it proper to furnish a more exact account of the doings of that establishment during the period named. It is important that the public should be correctly informed as to the state of the metallic currency of the United Kingdom, and the extent to which it is increased or diminished in each year. The official returns for 1861 have only recently made their appearance, although we know of no reason why they should not have been published many months ago. From those returns we gather that in the past year there was forwarded from the Bank of England to the Mint, for the purpose of conversion into sovereigns, 1,922,988,584 ounces of standard gold, and this yielded 7,487,636*l.* sterling. The quantity of standard gold imported from the same place for conversion into half-sovereigns was 145,215,788 oz., and this produced 1,130,867 coins of that denomination, or 565,433*l.* sterling. The total value of the gold coinage for the year 1861 amounted, therefore, to 8,053,069*l.* sterling. We believe that we shall be violating no rule or regulation of the Mint if we state further that, in the numerous processes employed at that place for the purpose of transforming the Bank ingots into current coin, *no loss* of metal whatever was sustained, either by waste, punctation, or any other cause. The importance of this statement, the accuracy of which we guarantee, will be appreciated by our readers, especially when it is remembered that the weight of those ingots was over 80 tons. It is, indeed, but an act of simple justice to Mr. Graham, master-worker of the Mint, and his staff of officers and men, to make this fact known. It is questionable whether, in any other money manufactory in the world, the same extent of accuracy has been attained. Prior to the year 1856, when the present Master of the Royal Mint made considerable changes in the executive department of the Tower Hill establishment, a very different state of things obtained. It was then no uncommon thing for the "working losses" of the Mint to be set down at 700*l.* upon each million sterling of gold coined there. Surely it cannot but be interesting to the public, who were called upon to make good the deficiencies, to learn that the words "working loss" are now positively unknown at the Mint, and that it returns to the Bank, weight for weight, in gold coins just what it receives in ingots.

Turning now to the silver coinage of the year 1861, we find that there were struck at the Mint presses between Jan. 1 and Dec. 31, of florins 839,520, representing a value of 83,952*l.*; of shillings 1,382,040, or in value 69,102*l.*; of sixpences 601,920, of the value of 15,048*l.*; of threepences there were struck, in the same period, the enormous number of 3,299,208, or in value 41,240*l.* worth. Besides these there were coined at the Mint in 1861 what are known as the Maunday monies of the year, consisting of silver pieces of the respective value of 4*d.*, 3*d.*, 2*d.*, and 1*d.* each, and amounting in aggregate value to 198*l.* We omit the account of sundry colonial coinages of silver, &c., which were conducted at the Mint, and state that the total value of the silver coinage for Great Britain during the year in question was 209,484*l.* The amount of worn silver coin purchased, at its nominal value, from the Bank of England for re-coinage was 97,600*l.* The Mint value of this, at 5*s.* 6*d.* per ounce, however, was only 84,940*l.* 1*s.* 10*d.*, so that a loss occurred by the transaction to the extent of 12,659*l.* 18*s.* 2*d.* This loss, resulting from the abrasion of the coinage in the wear and tear of circulation, has to be borne by the public treasury; and it is a singular fact, and one speaking eloquently of the commercial activity of our time, that every year it increases in extent. Sixpences especially are short-lived. They do an enormous amount of duty in a very little time, and are therefore soon worn out. It would be curious to learn the value and the variety of materials which each smooth-faced sixpence has purchased in its passage through the channels of circulation—in its journeyings from the Mint press to the time of its return to the Mint crucible. It is unfortunate that the smooth-faced coin has not a tongue to tell its own story. Certain it is that that story would be a strange one, and perhaps more thrilling than any penned by Charles Dickens or Wilkie Collins! Another question in reference to the loss sustained by the Mint in its purchase of old coin for re-coinage is, What has become of the 12,659*l.* 18*s.* 2*d.* worth of silver abraded from the surfaces of the used-up pieces of money? It exists somewhere, unquestionably. Perhaps some very enterprising gentleman may take a hint from the query, and organise a Company (limited) for the "recovery of the particles of gold and "silver annually lost in the circulation of our "metallic currency." We *have* heard of schemes not *more* likely to pay than this, and possibly there may be some afoot, even now, which have not so good a chance of success.

Let us return, however, to the realms of fact, and leave those of speculation, into which the loss of money led us. We have seen what was effected at the Royal Mint in the shape of gold and silver coinages during the year 1861, and it would be unjust not to note also its dealings with the humbler, but very useful, coinage of bronze. We find, then, that the Mint, assisted largely by contractors at Birmingham—Messrs. James Watt & Company—produced in 1861, of bronze pence 36,449,280, or in value 151,872*l.*, and in weight 339 tons; of halfpence 54,118,400, in value 112,746*l.* 13*s.* 4*d.*, and in weight 302 tons. Of farthings, which appear to be more and more disliked, and disused by the public, there were struck only 8,601,600, representing in value 8,960*l.*, and weighing 24 tons. The total value of the bronze coinage executed at Tower Hill, London, and Soho, Birmingham, during the year of grace referred to, was 273,578*l.* 13*s.* 4*d.*, and its weight, 665 tons. The cost of the copper and other materials, in the shape of old coins and new metal, for the purposes of the bronze coinage, was 96,735*l.* 6*s.* 8*d.* By comparing this last sum with the nominal value of the pence, halfpence, and farthings, coined and issued, the amount of profit accruing to the public exchequer in the transition from heavy copper to light bronze coins will become strikingly apparent.

It may be stated, finally, that no crowns, half-crowns, nor fourpenny pieces, except the Maunday groats, were struck in 1861, and that the whole series are fast becoming obsolete.

AN EFFICIENT IRON-CLAD FLEET.

Our iron-clad Navy has become, as we long ago predicted it would, the paramount national question. Even after the close of the session, in which it engrossed a larger share of public attention than any other, and gave rise to the most animated debates in both Houses of Parliament, the subject has retained its vitality, and promises to be kept in a permanent state of agitation until a satisfactory solution of the disputed theories it involves is arrived at. Nor is it to be wondered at that this great question should excite the most earnest controversy. Its immense importance is felt throughout the country; and whether we consider it with reference to the national defences or the naval expenditure, it cannot cease to command the public interest.

The Parliamentary debates left the whole question of our coast and harbour defences in a state of uncertainty. The dogged determination of Lord Palmerston to carry out his scheme of inland fortifications, which is a perfect mania, overrode every other consideration, even to the sacrifice of his darling object—namely, protection of the country against foreign aggression—which he would have us believe is, and has been, the cherished motive of his public life. On the Spithead Forts motion his administration suffered a complete and decisive defeat, and there is not a shadow of doubt that his National Defences Bill would have been thrown out, and his tenure of office brought to a sudden termination, if he had not made it a party question by threatening a dissolution if his adherents did not support him. They yielded, and sacrificed the national interest. We do not make these remarks in any party spirit, because we keep aloof from party; but when a party manœuvre, or a party weakness, to use the mildest term, imperils the national safety and wastes the public money in a department which comes within the scope of the supervision of this journal, we should fail in our duty did we not speak out plainly.

We are grieved that Parliament separated without imposing upon the Admiralty any definite conditions for the construction of an iron-clad fleet. What that department is required to do, or intends to do, is left in absolute and perplexing doubt. We have still ringing in our ears the parting and ominous words of the Earl of Ellenborough: "If "England do not possess an iron-clad navy "larger and more efficient than the navy of "other maritime states, she will lose her su-"premacy at sea; and if she lose the supre-"macy at sea, she will cease to be a first-class "power."

The Duke of Somerset heard these words, and his strong good sense must convince him of their truth; and yet how is it that he allows himself to be entangled in the routine and traditions of the Admiralty, the euphemisms for the gross maladministration of that department, to such an extent as to become the slave of the Controller of the Navy? On no other hypothesis can the dereliction or compromise of duty of the First Lord of the Admiralty be accounted for. In this state of things it is not surprising that the bitter animosities of Parliamentary discussion on the much-vexed question, and the measures of the

Admiralty for the construction of armour-plated men-of-war, should at an early day after the prorogation find representatives and advocates or opponents in the press.

Two champions from the opposite camps have taken the field. Mr. Scott Russell has opened a violent and direct attack on the Admiralty, making the Duke of Somerset personally accountable for its alleged delinquencies, and Mr. E. J. Reed comes forward in defence of that department. The columns of the *Times* are the arena of the combatants, and the editor of that journal has taken a part in the conflict, which is assuming the aspect of a "pretty quarrel" of that warm character which usually reveals the truth to lookers-on. The *Times* appears uneasy about its patrons, or *protégés*—we do not know which to call them—at the Admiralty, and in a temporising article steps in as mediator, admitting there is much truth on both sides of the question. Without partiality or prejudice for either side, we will endeavour to place the matter in dispute in the right point of view.

Mr. Scott Russell charges the Admiralty with waste in having expended twelve millions during the last three years, and produced only two vessels, the Warrior and the Black Prince, of that efficient armour-plated class which he contends alone are of any avail, as a part of our fleet in the present state of naval warfare. Except for the construction of these two ships, costing about a million, he says the remainder of the twelve millions has been wasted on wooden screw steamers, which when they were built were known to be out of date, and on the Valiant and Resistance class of iron-clad vessels, which he pronounces to be "tubs," and of no use for actual naval warfare. He then reviews the Admiralty statements of iron-clad ships under construction, and, from their own admission, shows that these will not be completed till 1864, by which time 8,000,000*l.* more will have been expended, making with the previous expenditure of 12,000,000, a total of 20,000,000*l.*, for which he says we shall have, supposing the Admiralty's anticipations to be realised, four more Warriors, which he values at 2,000,000*l.*, and nine other vessels of a heterogeneous character, including four iron tubs and five wooden ships, iron-cased, all of which he considers dear at 3,000,000*l.* He then completes his sum, and, charging the Admiralty with 20,000,000*l.*, he credits them with 6,000,000*l.* value received. This is the form and the gravamen of the accusation of waste, and in a financial and administrative point of view the indictment is a serious one. But to our mind this arithmetical calculation, founded on assumed and uncertain data, is a loose and unsatisfactory mode of treating a vital national question; and it is a kind of attack which may be met, if not rebuked, with a change in the figures and denominations calculated to puzzle the assailant and mystify the public. This precisely is the tack taken by the *Times*; and we do not consider Mr. Scott Russell's assault upon the Admiralty either judicious or fortunate. He has generalised and assumed so much, and so mixed up the obscure past, comprising three administrations, and the hazy future of more than two years, that he has done nothing to elucidate the present or advance the cause he has taken in hand. The mode of attack for attaining the object in view, which essentially is the prompt construction of an effective iron-clad navy, is not to cry over spoilt milk, and tax the Duke of Somerset with the delinquencies of his predecessors, or to enter into forced or fanciful estimates to establish a great waste, but to assail the Admiralty for its present shortcomings and provoke a categorical explanation of its intentions.

Mr. Reed is adroit enough to perceive the weakness of the attack, and he assists to deepen the mystification in which his adversary unwittingly envelopes the mal-administration and self-willed persistence of the Admiralty in their slavish dependence on the Controller's department. Of this department Mr. Reed is an employé, and he naturally labours *con amore* in its defence; but he is also, as it is well known, the inventor of that combination of wooden bottoms and iron-top sides which has been eagerly adopted by the Controller of the Navy as a compromise, enabling him to continue the construction of wooden vessels in spite of the adverse opinion of the most eminent ship-builders and engineers, and in direct opposition to the pledge given by ministers to the House of Commons, that no more wooden vessels would be built.

In this controversy between two naval architects, the real question is frittered away in the discussion of technical and financial points, and in supporting the particulars, plans, or modes of construction of which each claims to be the inventor or promoter. Mr. Scott Russell is all for speed and power combined, which he imagines are to be attained by fine lines and immense length in iron-built ships, of which in his mind the Warrior is the "beau-ideal." Mr. Reed is also the advocate for speed, not only for the colossal Warriors and Northumberlands, which, as the offspring of the Controller's office, he will not disparage, but for cruisers in all parts of the world where England must hold the command of the seas and protect her commerce and dependencies. In his own explanatory statement, when the design of the Enterprise was somewhat rudely assailed, Mr. Reed deliberately admitted that to be his object, and he avowed that to attain speed, combined with partial protection and diminished draught, "wooden bottoms" were his universal panacea.

We would guard the public against being misled by the professional squabbles of rival constructors, or by the blunder and pretence of raising an issue on "Admiralty Waste," as these discussions, at the present critical moment, divert attention from the vital question of the total inefficiency of the Admiralty organisation for constructing such an iron-clad fleet as shall maintain our supremacy at sea, with the loss of which we are threatened.

The revolution in naval warfare is an established fact. In a series of articles we laboured for some time in impressing that fact on the public mind, and we believe not unsuccessfully. We raised the question of "power or "speed for the navy?" and the position we took (under the new phrase of invulnerable iron walls for ships' sides), that *power* is the primary condition, has not been refuted. Now, if this position be true, we can at a breath blow away the chaff and exhibit the grain of the Russell and Reed controversy, and disconcert the tortuous policy of the Admiralty press in agitating points of secondary importance as if they were the main issue.

What England wants, and what England is prepared to pay for, is an efficient iron-clad fleet, comprising vessels of all the classes required for the different services; and, to clear away the ground, we will at once say, neither the much-prized Warriors of the Admiralty and Mr. Scott Russell, nor the timber-bottomed Enterprises of Mr. E. J. Reed, are worthy of serving as types of either the required classes. The Warrior is unprotected at both ends, and, therefore, might be disabled by a few broadsides; she steers and rolls awfully, leaks through the joints of her armour like a sieve, and, worst of all, she is armour-plated in so defective a manner that, by the admission of the First Lord of the Admiralty, and from the result of the experiments at Shoeburyness, the through bolts which form the fastenings are liable to be destroyed by a few discharges of shot, and the plates to fall bodily off the side of the ship. As to the Enterprise, it would be a waste of time to repeat the objections to a system of construction which sacrifices power to speed, and produces a partially-protected wooden vessel, which would be as speedily crushed in an encounter with a completely iron-clad ship as a whole fleet of Federal half-clad gun-boats has lately been put *hors de combat* by a single Confederate iron monster.

We adhere to the theory deliberately adopted and promulgated in the "Magazine," that, with the altered construction of war ships, invulnerability is the first consideration. Speed, of necessity, becomes a secondary one, because the two conditions, however desirable, cannot, in the nature of things, be combined in the same vessel. By power, we mean defensive as well as aggressive power; and the two united demand a maximum weight of iron armour and guns which renders the combination of the greatest power and the greatest speed in the same vessel an impracticable and visionary scheme.

Mr. Reed having recourse to the small weapon of verbal criticism, makes Mr. Scott Russell say what he did not say, namely, that the Admiralty are building no iron-cased "fleet at all." Mr. Scott Russell's statements are, not that no fleet at all is being built, but—

1. That we have no fleet at present, and the two Warriors and two Defences cannot be said to constitute a fleet.

2. That the vessels launched, and those under construction, will form an *inefficient* fleet.

3. That we must wait until some indefinite period in 1864 before even this inefficient fleet will be in existence.

It is hardly fair in Mr. Reed thus to misrepresent Mr. Russell's obvious meaning, and hardly prudent, as a public servant, to publish a long letter of which that misrepresentation is the burthen. We are not going to mix ourselves up with the personalities in which both writers have indulged; but we fear it will be thought by many readers that Mr. Reed, in his remarks on Sir Morton Peto and Mr. Russell, has not displayed good taste, and is himself not free from the "poor spirit" of which he complains in them.

Resuming the subject of "an efficient iron-"clad fleet," there can, we think, be no doubt that it must be composed of four classes:—

1. Floating fortifications and batteries for harbour and coast defences. These should be of the same character, but of two kinds, differing in tonnage and powers of locomotion. They would be protected with the strongest and heaviest iron armour they could carry, and armed with the heaviest guns that could be constructed. They should be fortresses afloat, so invulnerable and so powerful in armament that no sea-going ships could contend against them. For the defence of the channels leading to a dockyard or arsenal, as at Spithead, the largest vessels of this description would be permanently stationed. They would replace the proposed fixed forts, and be constant ramparts of defence. They would not require great speed, as their duties would be, not to escape from or give chase to an enemy, but to oppose his approach or entrance into the Channel, and, if he entered by surprise, to follow him up and engage him in close conflict; in which such floating batteries on the revolving

power, or some other gun-shield plan affording complete protection to the crew, would have a decided superiority over any Warrior or La Gloire sea-going ships that could be built. For coast protection, the vessels would be of the same character, but smaller dimensions and greater locomotive power, so as to be able to steam readily to any point of danger, and repel invasion.

2. Line-of-battle ships carrying the strongest armour-plating and the heaviest armament consistent with the moderate degree of speed required, to manœuvre and maintain their position in a line of battle. These vessels should be not partially but wholly protected from stem to stern, and especially between wind and water. Neither weight of armour nor of guns must be diminished for the sake of speed. Better to sacrifice two or three knots an hour and have increased power, offensive and defensive, in the day of battle. The history of great naval battles teaches us that speed is not an essential property of the sea giants which engage in those tremendous conflicts. When the powerful fleets of hostile maritime powers put to sea, their object is not to avoid but to seek and encounter the enemy and fight a great battle; and if flight after defeat might render speed desirable, the deficiency of that strength which was sacrificed for the sake of speed would probably be the cause which made flight necessary.

3. Cruisers of every denomination which would carry a lighter armament, and comprise in their construction all the requisites of speed and power consistent with sufficient protection, and the means of contending successfully against an enemy's cruisers of the same class.

4. Gun and mortar boats for service in rivers and shallow waters at home and abroad.

It is not our purpose now to enter into the details of the requisite conditions of construction, but simply to designate the character of the vessels of this and the other classes. By an intelligent adherence to this classification, and constructing each class perfect in its kind, the Admiralty might endow the country with an efficient navy; but to carry out this programme successfully there must be a thorough reform in Admiralty administration, and a much higher order of engineering talent must be brought into action than that which designed the half-protected, unmanageable Warriors, the Defence tubs, or the "wooden-bottomed" Enterprises.

MAIN DRAINAGE WORKS OF THE METROPOLIS.

The main drainage works for the metropolis are really making rapid progress. On Saturday last an inspection took place under the guidance of Mr. Thwaites (whom we are glad to see convalescent) and Mr. Bazalgetti. The entire staff of officers of the Metropolitan Board of Works and a large number of visitors were present. The party started by steamboat from Hungerford Market between eleven and twelve o'clock for Greenwich, and upon landing at the pier they at once proceeded to the immense sewer constructed by Mr. Webster, extending from Deptford Creek to Crossness Point, Plumstead Marshes. This sewer is completely circular, 11ft. 6in. in diameter, and 18in. thick, except that part of it which passes under Woolwich, where it is 2ft. thick and seven miles and a half in length. The sewer was lighted by hundreds of candles placed at regular distances from each other; and the effect when viewed, as far as the eye could reach, was really marvellous. The pumping station at Deptford was next examined, by means of which the sewage will be pumped from the low level to the high level sewer; and the magnitude of the works excited the greatest surprise.

The whole of the company were then escorted to the river side, where a steamboat was in waiting, and they crossed over to the Bow and Stratford branch of the Eastern Counties Railway, and on it were conveyed to Old Ford. Here the completed northern high level from Hampstead, a length of 9½ miles, and the work of Mr. Moxon, was examined, together with the penstock chamber and overflow channels. Here is a junction of the Middle Level Sewer, 12ft. in diameter, and by the aid of the penstock and overflow channels, the sewage can either be continued on its course to the outlet or passed into the River Lea, which at present receives the sewage of that district. From this point the Northern Outfall Sewer is now in the course of construction by Mr. Furness, and will terminate at Barking Creek. This work will be 5½ miles in length, consisting of double and treble lines of sewers, each 9ft. in diameter, and for a considerable distance they will be from 15ft. to 17ft. above the level of the surrounding land, the sewers themselves either resting on an embankment or brick arches. In its line there will be seven aqueducts over rivers, two aqueducts over railways, and the materials employed in the construction of the sewers, concrete embankment and substructure of arches through the marshes, will consist of 20,000 rods of brickwork, 500,000 yards of concrete, and 100,000,000 bricks. The contract price is 625,000*l*. These sewers at Barking will discharge into a reservoir, which will cover an area of no less than 12 acres, and from this reservoir it will be discharged into the river during the ebb of the tide. All these works were minutely examined, the party proceeding to Barking in the contractor's trucks on a railway laid down to facilitate the carriage of materials from the river to different parts of the works.

After the inspection a luncheon was enjoyed, and several congratulatory speeches delivered.

INFLUENCE OF RAILWAY TRAVELLING ON HEALTH.

Our readers will remember that we published a few months since a valuable paper, which was read before the Society of Arts, on the influence of railway travelling on health. Since that time the question has been amply discussed in the pages of the *Lancet*. The series of papers on the question in that journal are now published in a pamphlet by Hardwicke, Piccadilly. The following summary cannot be too widely circulated:—

It is unnecessary to do more than allude to the accumulated evidence which accomplished observers of health and disease have contributed to our report on the influence of railway travelling on the various organs and parts of the body in health and disease.

The efficiency of the rapid concussions incidental to railway travelling in developing or aggravating epilepsy, clonic spasm, cerebral softening, and spinal softening, has been studied, not by the light of vague conjecture, but upon the authority of strictly-observed cases in the practice of Sir Ranald Martin, Dr. Brown-Séquard, Dr. Radcliffe, Mr. Ernest Hart, and others. The particular influence of cold and draught has been brought out prominently by Dr. Williams; while this has been placed in necessary juxtaposition with the exact enquiries as to ventilation and relative purity of the air in railway carriages by Dr. Angus Smith. The mischief following from undue retention of the secretions is sufficiently and practically illustrated in the case by Mr. Hilton. The nature of the impressions on the eye, so well studied by Sir David Brewster, has been traced to its pathological consequences by Mr. White Cooper. Dr. Fuller's ingenious observations on the part played by the auditory nerve in conveying to the brain strong and incessantly repeated impressions of sound, are of a practical and suggestive character. This is, no doubt, one cause of the peculiar effects of continued railway travelling which had not been well known, and of which the mischief is preventable. The almost certainty with which a long railway journey will, in some pregnant women, produce abortion, has been well illustrated in the communications by Dr. Meadows and Dr. Graily Hewitt. The acceleration of the pulse in railway travelling is one of the indications of the extent to which this form of passive exercise taxes the system; but all physiological deductions require to be received with great reservation, as the disturbing elements are so many and various.

There are only two classes of persons especially likely to be injuriously affected by moderate railway journeys, even though frequent: they are persons advanced in life and of weakened power, and those who are subject to the special diseases which have already been studied in this relation. The actual exertion, the excitement, the mental strain, the peculiar influences of the motion of a railway carriage, indicate its dangers to those first mentioned. These constitute a small minority. But there are a number of persons who, although not far advanced in age, are yet the subjects of various conditions of ill health depending on insidious degenerative disease of the brain and heart. The season-ticket holders of the railways are, in large numbers, men who have passed the best years of their life in hard and exhausting employment of mind and body. They are the successful merchants; the senior partners of flourishing firms, which they have built up by a life of labour; half-retired tradesmen; half-invalid bankers, *et id genus omne*. We can now see that it is by the injuries which have resulted to these men from their constant travelling to and from town that an impression has become current as to certain mischiefs which habitual travelling inflicts. When it was known that such a banker, who comes up fifty miles three or four times a week, has to lie down half an hour before he can sign a cheque, that such a well-known chemist has suffered from symptoms of brain excitement since he bought his new house by the sea and travelled daily to London, or that a certain barrister has found himself obliged to pay for his journey by epileptic seizures, the alarm soon extended beyond reasonable limits. But few men can endure without suffering to travel fifty or a hundred miles daily to their business for any length of time. The influence of the journey itself is heightened by many accessory conditions to which we have adverted; and the present construction of the rails and carriages is such as to deprive the traveller of all those mitigations by which his discomfort might be diminished and his health safe-guarded.

Catching the train.—Amongst the unprecedented collection of cases brought under our notice during this enquiry, there have been recorded several of serious mischief, and even death, from persons in ill health hurrying to catch trains, and sitting down, heated and breathless, in the draught caused by the moving of the train which they have just managed to be in time for. It is almost exclusively at large termini that these cases have occurred, and that the cause of them obtains. Now, this rushing in at the last moment, we are informed, is becoming more frequent; and consideration of the condition in life of those who constitute the majority of season-ticket holders would indicate how this evil arises. We believe it would be advantageous to public health and safety, however harsh it may at first appear, that the doors at termini should be closed five minutes previous to the departure of each train, so that sufficient time should be allowed for passengers to quietly settle themselves, and also for the officials, who are often (as one of them graphically expressed it) "torn to pieces" just at the last moment. It is well known that the difficulties with luggage, which this arrangement would obviate, are frequently causes of delay in starting trains. Then there is high speed to make up lost time or want of punctuality—both of them fraught with danger to passengers.

Cautions to habitual travellers.—It has been shown that the injurious effects which habitual railway travelling produces on some who escape such influences when only taking occasional journeys are very marked. In such persons heedless continuance comes to be a cause of disease. In some, there have been no previous symptoms that

they could recognise, or such as would have deterred them from undertaking the daily journey; and thus the season-ticket is taken, and has soon to be disused, or the health suffers. In all cases the evidence points to the conclusion that the injurious influence slowly and gradually increases whilst the cause remains—that tolerance is not established by persistence.

It is too much the custom, when adopting a country residence on a railway line, to make no new arrangements of business according to the diminished time for work which the daily interval between the morning and evening trains allow: hence that hurry, anxiety, and working of the brain at high pressure, which of all things tend to develope in susceptible persons such injurious effects on health as habitual railway travellers often experience. The remedy for this is obvious: "Cut your coat according to your cloth"—"Meno tenus propriâ vive"—"Selon le pain il faut le couteau"—are saws proved to be wise. But we believe that no person is justified in undertaking a series of continuous journeys by rail under the conditions alluded to (if under any circumstances) without previously consulting his medical attendant as to their probable effect on his health, the precautions he should adopt, and the warning symptoms which he may not safely disregard. In aid of such decisions, we trust that these reports, now brought to a conclusion, may prove helpful.

AMERICAN INVENTIONS.

At a recent meeting of the Franklin Institute, Philadelphia, Mr. Howson exhibited a patent naphthometer, or benzine detector. This is the invention of Messrs. H. J. Smith and Woodruff Jones of this city. The instrument consists of a reservoir with a tightly-fitting cover, from the top of which projects a tube, surrounding a wick tube. A thermometer also passes through the cover, and occupies such a position that its bulb comes within a short distance from the bottom of the reservoir. In order to determine the temperature at which the oil gives off sufficient vapour to cause an explosion, the oil to be tested is poured into the reservoir, the wick is lighted, and the instrument placed on a stove, or over the flame of a lamp. At a temperature which varies in proportion to the quantity of explosive ingredients contained in the oil, the vapour is given off, and mixing with the air in the reservoir passes up through the space between the wick tube and the larger tube, and explodes when ignited by the flame, thereby extinguishing the light. The height of the mercury in the thermometer will determine the quality of the oil. The contrivance is very simple and cheap, and enables anyone to ascertain in a few minutes whether an oil is of a quality to be burned with safety.

A heater to be applied to coal oil lamps was also exhibited by Mr. Howson. This instrument, the invention of Mr. Woodruff Jones, is intended to be used in sick chambers for heating articles of diet, &c. It consists of a metal cylinder or casing, the upper edge of which is provided with a ring, and the lower with a flanch adapted to the burner of a coal oil lamp, so that the heat of the flame may be communicated to articles of food, &c., contained in a vessel resting on the ring.

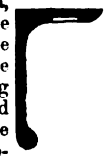
Mr. Howson then explained Mr. Cooley's patent mode of discharging projectiles. The shot or shell has an orifice into which fits a solid cylinder, and between the end of the latter and the end of the recess intervenes the charge of powder. The cylinder is surrounded with a shield, which prevents the products of the ignition from injuring the gunners.

Mr. Howson also exhibited a cavalry sword and several varieties of tools with the gum elastic handles, patented by M. C. Bogia, Esq. These handles have been highly approved of as presenting a slightly yielding surface, and one which affords the means of maintaining a firm grip in the hand. It is applicable to all descriptions of tools.

A. F. Ward exhibited charts, and explained his system of semaphoric colour signals. This system has been brought to a high state of perfection by Mr. Ward, and has been recommended to Congress by the Board of Trade of this city.

Mr. John W. Nystrom exhibited some specimens of angle-iron and keel-gutter, made by him at General Maltsoff's establishment in Russia, and made the following remarks:—

This form of angle-iron is best adapted for frames and beams in river steamers of light draft. The dimensions of one of the specimens shown is $1\frac{7}{8} \times \frac{5}{16} + 2\frac{7}{8} \times \frac{3}{16}$ inches, weighing 4·125lbs. per foot; and of the other, $2\frac{1}{2} \times \frac{3}{8} + 4 \times \frac{1}{4}$ inches, weighing 5·47lbs. per foot. The improvements in this angle-iron consist, 1st, in a bead on the one edge, which makes it stronger, and about 20 per cent. lighter than ordinary angle-iron. Experiments on its strength were made in Russia, but the results have been lost. The bead is placed on the inside of the angle-iron, so as to make the frame lie flat on the cast-iron form when bending it. 2nd, the countersunk holes rolled in the angle-iron, as shown in the sample. In the ordinary iron ship-building practice, the angle-iron is generally bent into the shape of the frames, after which the holes are drilled in. If the holes are punched first, the angle-iron does not bend so well, and the holes will get out of shape in sharp curves. When the angle-iron is bent, the holes cannot be punched, because the punching would throw it out of shape. Now, rolling the countersink, leaving a thickness of about one-eighth of an inch, allows the angle-iron to be bent into shape, after which the balance of the holes are punched out by a hand-press without altering the shape of the frame. In Russia, I had it so arranged that the angle-iron was taken direct from the rolling-mill, bent and bevelled to the true shape of the frame in the one original heat as fast as the angle-iron could be rolled. The deck-beams were made of similar sections to the frames, but of larger size, and bent into shape in the original rolling heat.



The third sample here exhibited is the form of the keel of the steamers which I built in Russia. It is in the form of a U, with rolled countersinks. We called it the keel-gutter, because it is used for that purpose in conveying the bilge-water to the pumps.

Except for balloon navigation, there is no case where combined strength and lightness require such careful consideration as in light draft river steamers, where an inch or two more draft of water may render navigation impossible. One river steamer, the Astracan, which I built for the river Volga, was of the following dimensions:—Length in water-line, 234ft.; breadth of beam, 22ft.; engines, oscillating; two cylinders, 54 by 54in. To carry 400 passengers and 32 tons freight, including 8 tons for passengers' baggage; with fuel on board for six hours at a speed of 20 to 25 versts per hour, the steamer drew only 3ft. 4in. of water. The angle-iron in that steamer amounted to 9,000ft., which, with 20 per cent. difference in weight, will be about 8,000lbs., or about 50 passengers, or about 2in. in draft of water.

THE PHYSIOLOGY OF SEA-SICKNESS.*

By Richard Meade Bache,
Assistant U. S. Coast Survey.

(Concluded from page 85.)

At sea, motion immediately nauseates, even when it is much less than may be experienced in a swing without the slightest impression. In a swing motion is comparatively regular. It requires little education of the senses to enable them to keep pace with each other. The evidence of the sight is nearly the same as that of the feeling. If a person in a swing is blind, or keeps the eyes shut, there are still measures of the extent of motion. These measures are, firstly, the points of highest elevation and greatest depression—secondly, the corresponding intervals of time—thirdly, the perception of the rush in progressing through the atmosphere; for not only does the cessation of the rush indicate the points of greatest elevation, but its increase or diminution indicates continuously all other points. Hearing may also be mentioned, as it contributes to the conviction of the mind as to the uniformity of the motion to which the body is subjected when swinging. All these certainly give a most accurate idea of the segment of a circle which the body is describing in the air. Nausea can be produced in a swing, but it requires very little education of the senses to enable a person to bear the motion.

I have been told by a person who attempted to prepare himself for a sea voyage by using a swing, that the process was entirely unavailing: yet I doubt very much whether the motion to which one is subjected at sea is often greater than can be attained in a well-constructed swing. But the motion of a swing is quite uniform; that at sea far from it: and the failure of the swing to inure a person to unequal motion, shows that it is not motion which affects us, but inequality of motion, and that it is not the mere mass of flesh and digestive organs which are alone concerned, but other elements as appurtenances of the body demand our consideration, and, as I hope to prove, merit it far more than the mere body and stomach, which becoming diseased only react. If it be said that animals, such as horses and dogs, become sea-sick, and yet have no such nice senses as we have, excepting perhaps scent, I answer by saying that a horse is always terrified at movement in which he does not see the cause, even terrified at perfectly noiseless movement. What is it which prompts a young dog to jump at all hazards from a vehicle in rapid motion, even when driven by his own master, and what makes him eventually delight in riding? Preconceived ideas of motion, when violated, bring terror to both horse and dog. The conditions of novel motion once accepted, the senses are reconciled, and habit is the result. If, then, we allow these animals to possess habitual conception of motion, they must be affected at sea as human beings are in the same manner if not in the same degree. The tumbler pigeon precipitates itself with a revolving motion towards the earth, but does not appear to be at all affected by the motion which its body has undergone. If the same bird is taken in the hand and its head placed under one of its wings, and it is then whirled around, it may be placed on a table, and during a few moments it will appear lifeless. Aquatic birds of the greatest vigour in flight, and habituated to floating on stormy waves, often become nauseated on the decks of vessels.

Let us now consider the motions at sea. A ship rolls, plunges, seems to pause, then dart, and every movement brings the passenger increased uneasiness. There is no precedent in his experience for such movement. If he possesses sight, the view of objects is at variance with all that he has been habituated to in other motions. If he is blind, his mental conception—the picture in his mind—is equally at variance with his habitual conception. In a few days, in either case, the person would be indifferent to the motion. He will have learned, in the meantime, to reconcile the evidence of his senses. If he possesses sight, it will have been educated in conformity with unequal motions, just as it was educated from childhood to comparatively equal ones; or if he is blind, his conception of the appearance of motion will have been reconciled with motion experienced. In either case it is the conception of the appearance of motion as contrasted with the feeling, which conception will have reconciled itself with existing conditions. Both those who see, and the blind, possess this habitual conception, which is never shut out from the mind, as has been shown. Closing the eyes will not discard it. If it did, everyone subjected to unusual motion could in that way secure immunity from nausea. This has been shown not to be the case.

Let us now consider the peculiar effect of unequal motions upon the human body. It is my conviction that motion is nauseating whenever the estimate of its extent does not correctly precede it.

* Read before the Connecticut Academy of Arts and Sciences, January 15, 1862.

The mind mechanically calculates what is to take place while it is taking place.

I shall now endeavour to show that "motion is nauseating whenever the estimate of its extent does not correctly precede it." I have already shown that motion is not nauseating per se. I have also shown that when it does nauseate, it is when the brain is impressed. The question naturally suggests itself here as to what there is in the impression produced on the brain which affects us unpleasantly and produces nausea. It is the idea of undefined movement of the body of the observer. Back of this I do not pretend to go. Nature has so constituted us that undefined motion is repugnant to our organisations. Nauseation from motion proceeds from the idea present to the imagination, that the body is the subject of undefined motion. The nauseation of sea-sickness, of course, eminently proceeds from undefined motion. But to the proof—an experiment which anyone can make. I have often lain awake at night in the cabin of some great ship at sea, and gauged the motion and calculated the capability of the passengers to resist an access of nausea. Choose a time when there is a regular sea and wind, when the ship ploughs along pretty evenly. Now and then seas will rise somewhat higher than the rest. Sea-sick passengers habituated to uniform motion, at the intervals when the ship has been accustomed to rise or to fall, feel that they rise still higher or fall still lower. The difference in motion is not perceptible in violence, and yet causes many to give involuntary evidence of the occupancy of their state rooms. The strain of fancy is ever exerted and *solicitous* to imagine and attain the turning point, although after it is gained the motion, as in a descent, may be still more rapid. Let anyone who has been at sea recall how trying was a continuous movement in one direction, even a long rise upon a wave, when the motion is certainly not as swift as in a descent; and at the same time remember how small the motion of a long gliding rise or descent is as compared to much that one is subjected to at sea—how much less violent. The effect upon the observer is produced simply by the difference of motion—by ignorance of the extent to which it is going—by the idea of undefined motion. When one's senses are educated in the novel condition of existence at sea, the motion is no longer undefined. A ship could make no movement which would not be accompanied by a corresponding idea of space passed through. There is no motion at sea which by habit will not cease to appear undefined, but if it were possible for a ship to mount heavenwards, and to sink rapidly near to the bottom of the sea in alternate movements, it is my belief that the hardiest sailor would become sea-sick.

The summary of what I have attempted to demonstrate is this, that sea-sickness is not the result of motion per se, nor of the appearance of motion per se, but is the result of the senses "violating the habitual conception of contrasted effects of motion," and producing on the brain the idea of undefined motion. When the senses are educated to form cooperating and agreeing measures of the novel condition of existence at sea, nausea ends. If they never formed these measures nausea would never end.

For another proof of this theory, take the case of an infant. Instances of children in arms being sea-sick are very rare. A child certainly feels the motion, that is to say, its body is subject to the motion equally with that of the oldest passenger. But a child undergoes motion without *feeling* it. It sees, too, without *perceiving*. In its case nothing conflicts. It is as ready to be rocked on the billows as in its cradle. Its youth precludes the possibility of its having any habitual conception of motion from the education of the senses, and if it feels any sensation, that sensation is at variance with nothing. As soon as children begin to "take notice," as it is called, the education of the senses begins, and thus we find that children shortly afterwards, at the age of two and three years, are attacked by sea-sickness, but they recover long before adults are secure from it. The case of a blind man, because he cannot see and consequently cannot perceive, is not in any respect similar to that of an infant, for I have shown that the mental picture may conflict with reality, and the blind man has the mental picture—the idea of space, motion, speed, everything, excepting colour. Not only are babies not usually afflicted with sea-sickness, but just in proportion to the youth of children are they exempt from it. Since my own observation indicated what has been asserted in regard to the immunity of babies from sea-sickness, I have enquired of persons of experience whether their observation tended in the same direction, and I have been confirmed in my belief.

It has been asked by a friend, to whom I communicated this theory of sea-sickness, whether the insane are sea-sick, and an answer in the negative would certainly seem to corroborate the theory. Thus far, however, I have been unable to ascertain, as the insane are so rarely allowed to go to sea that it would require long and patient investigation to determine the point. Immunity from sea-sickness in a very few cases might be a mere coincidence. As far as the answer has been made to my enquiries, I shall give the result. I know of two persons who, there is every reason to believe, never had been at sea until a voyage when they laboured under the "mania à potu." These persons did not become sea-sick. Another case of which I have reliable information, is that of a young girl who was insane, and who was taken to sea by her father, who was the captain of the ship. She, too, was not sea-sick. I should be very sorry to mar a strong case of evidence in favour of the theory which I have advanced, by an assertion of the truth of which I am not positive, even if I were willing to state anything of which I am not absolutely certain. I give my investigation of this subject for what it is worth in the thoughts of those who may read this article. I shall not support my theory in any measure whatever upon the result of that slight investigation; therefore I do not assert that the insane are not liable to sea-sickness.

I think it sufficiently clear from all that has been said, that impression of the brain is the cause of nausea on the ocean, since I have shown that it is not motion per se, nor the appearance of motion per se which causes it, but an *idea*, which I have termed one of undefined motion, derived, when the body is subjected to motion in an unusual manner, from the "violation of the habitual conception of contrasted effects of motion." There are minor causes of sea-sickness, or rather not so much causes as aggravations of it. These are close cabins, smell of bilge-water, unusual food, and, as I have said, the stomach reacts upon the brain.

A precaution frequently taken by people about to commence a sea voyage, is to eat nothing, or scarcely anything. Another precaution taken is to get immediately into a berth. Neither plan is good. Neptune is the most insatiable highwayman on the globe, and attempts to levy toll on all. The traveller who comes totally unprovided fares badly, if he cannot successfully resist. In plain English, the stomach is weakened by want of food, and is therefore more liable to be acted upon in the production of nausea, and if nausea should ensue, retching is probably more distressing without than with food. Lying down is an excellent plan to adopt for the purpose of avoiding nausea, but when the posture is assumed in a berth with the nauseous swell of bilge-water around, and, as is often the case, with a tin vessel of questionable nicety hooked on the edge of the berth, the plan is no better than the first.

Persons frequently imagine that some particular article of food cured their sea-sickness. It is a general rule that, whatever a sea-sick person is able to eat at all while sick, or convalescent, gets the credit of the cure. The most heterogeneous articles are spoken of as specifics. The best preparation to avoid sea-sickness is to go aboard ship with the stomach supplied with its accustomed amount of food. It is best, as far as possible, to maintain the habits of shore.

Many reasons combine to render the deck of a vessel in anything like fair weather the proper place to remain, either to avoid sea-sickness or to recover from it. It is there that the sight can be more quickly educated to the movement than it can be in the cabin. The crests and troughs of the seas can be observed, and thus it can be seen just how far one has to rise, just how far to fall. Persons will frequently find that a view of the waves has a beneficial effect in stilling nausea suffered more severely in the cabin. This is not only on account of the fresh air on deck, but because in the cabin the idea of motion is more undefined. The view of the horizon also has a most beneficial effect. The horizon is the only object which has the appearance of remaining stationary, and the motions of a ship are readily graduated by keeping the gaze directed to it. On deck the miserable sea-sick passenger can breathe the fresh air, in lieu of the conglomerate smells in a cabin aboard-ship. He can also choose a position amid-ships, where there is the least motion of any place on deck. Then there are more agreeable objects to look at on deck and beyond than in the cabin, and it is very important that the mind should be distracted from the passing scene, or what is disagreeable or most so in it.

If, in addition to what has been recommended, the passenger will spread a mattress and put himself in a recumbent posture, all will then have been done that can be done to prevent, to cure, or to alleviate sea-sickness, until the education of the senses is completed.

A NEW METAL IN THE NATIVE PLATINUM OF ROGUE RIVER, OREGON.

By C. F. Chandler,

Professor of Chemistry at Union College.

In examining native platinum from the above locality, more than a year ago, I became convinced of the probable existence of a hitherto unobserved metal. I have deferred publishing my observations, hoping to obtain material for a more complete examination; in this I have thus far been disappointed.

The quantity of platinum examined amounted to only a few grammes. It was digested with hydrochloric acid to remove impurities, and the solution thus obtained was subjected to the ordinary routine of qualitative analysis.

A brown precipitate was produced by hydrosulphuric acid, which dissolved readily in hydrochloric acid on the addition of a crystal of chlorate of potassa. In this solution metallic zinc produced a precipitate which resembled metallic tin obtained under similar circumstances. This precipitate dissolved readily in hydrochloric acid on the application of heat; but the solution thus obtained had no effect on a solution of protochloride of mercury (HgCl), and on cooling deposited a small quantity of minute crystals. To guard against error, these experiments were repeated two or three times on small portions of the original solution, always with the same result.

The chloride of this metal differs therefore from the protochloride of tin, in not reducing protochloride of mercury to calomel, and in being but slightly soluble in the cold.

On mentioning my observations to a friend, I was referred to Dr. F. A. Genth's announcement of a new metal, made in 1852, of which I was not previously aware.

The metal observed by Dr. Genth occurred among grains of platinum from California. It was malleable; it fused readily on charcoal before the blowpipe, becoming covered with a coating of black oxide; it dissolved in borax to a colourless bead, which became opalescent on cooling; it was dissolved by hot hydrochloric acid and by nitric acid; and its solution gave a brown precipitate with hydrosulphuric acid. It seems quite probable, therefore, that the metal which I have observed in the Rogue-River platinum is identical with that observed by Dr. Genth.—*Silliman's American Journal*, May 1862.

Schenectady, March 6, 1862.

SEVEN SUGGESTIONS,

Respectfully submitted by W. Austin, C.E., to His Grace the Duke of Somerset and the Lords of the Admiralty.

1. The formation of a flotilla of gun-boats and ships of war, as a "belt of guard-ships" round the coast, placed at ten or fifteen miles apart, at signalling distances, and changing berths successively through the belt, so that the officers and crews would thoroughly know the points and bearings of the general coast; and at a given signal fleets of thirty or forty sail could be congregated together, in a few hours, for defence of any assailable position.

2. The construction of sunk trenches or railway cuttings on the shores of beaches, cliffs, and headlands around the coasts of Great Britain, &c., with strong trams or railways and eight-wheel trucks, on which guns pivoted would be mounted, so as to revolve and fire all ways, and be propelled by steam or horse power — constituting a swift-running, or what may be termed a flying, battery for shore defences.

3. The construction of "floating breakwaters," which could, on emergency, be mounted with powerful guns or mortars, and form "floating batteries" for the entrances of harbours, channels, rivers, bays, &c., and which could, if necessity demanded, be temporarily sunk, and thus form "shoal obstructions" to entrance or passage of an enemy's ships.

4. The construction of "floating steam-ship gun batteries," to be driven ahead or astern by steam-paddles, placed inboard, with the capabilities of reversion and quick revolution, or turning around of the port and starboard broadsides in quick succession, and requiring no screw propeller or rudder, the head and stern being alike, and each formed and fitted for powerful ram action.

5. The construction of "iron armour shutter plates" inboard of the port-holes of ships, to protect the men at the guns whilst loading. These shot and shell proof shutters being easily moved to and fro by the hand, it would supersede the present ineffective iron plates.

6. A new mode for fixing armour plates to a wood ship's sides, so as to be easily removed and reinstated, if damaged in action, and also by being properly backed with hard rammed sand interstices, the plates would not be cracked or the timbers shivered by concussion. A lighter and stronger armour plate (without bolt-holes) is submitted in preference to the present lumbering plates, which cannot be handled but with immense powerful lifting gear, going into dock to repair.

7. The coating over the present timber-planking of ships' decks and sides with fire-proof and shot and shell proof flooring, so as to be impossible to set fire to a timber-built ship either by design or by accident.

THE ARMSTRONG GUNS.

The following conversation took place in the House of Commons on Thursday week relative to the Armstrong guns:—

Mr. Osborne wished to put a question to the Secretary for War. Certain experiments had recently been made at Shorncliffe with a light 12-pounder rifled gun, and especially as to the effect of rapid firing. He believed that a commission of officers had been appointed to report upon the condition of those 12-pounder guns after rapid firing, and he wished to ask, first, whether those officers had made any report upon the condition of the 12-pounder Armstrong gun after the experiments in rapid firing; and, next, whether it was true that a large proportion of those guns were altogether unserviceable, being greatly damaged by the shifting of the external coils, the splitting of the internal coils, the chipping of the screws, and the breaking of the vent pieces. (A laugh.)

Sir G. Lewis said, although he had notice of the intention of his hon. friend to ask a question, he had not been aware of the particular report to which he intended to refer. He had received a report from Colonel Cuppage of the results of certain experiments with the Armstrong 12-pounder gun, which had lately taken place at Shorncliffe, but those experiments were of three kinds. Some of the firing was at 1,000 yards against targets to try the effect of landing from boats; other experiments were at various ranges, in order to test some assumed defects in resisting cavalry; and, lastly, experiments to test the effects of rapid firing. He believed the report upon all the three classes of experiments was that they were eminently successful.

Mr. Osborne.—But as to the present condition of the guns? (Hear, hear.)

Sir G. C. Lewis.—The report relates to the success of all the experiments.

Mr. Osborne gave notice that next Session he would call the attention of the House to the present condition of the War Office, in regard to the management of rifled ordnance, and to the position of Sir W. Armstrong as Director of Rifled Ordnance. (Hear, hear.)

In reply to Sir De Lacy Evans, Sir G. Lewis said that it was impossible to lay any report upon the table during the present Session, but the hon. and gallant member could revive the subject in the next Session.

LAMBETH SUSPENSION BRIDGE.

The Lambeth Suspension Bridge, the cable of which was fixed a few weeks ago, will be completed in about two months. On the Westminster shore it was found on taking borings that there was a large deposit of peat, and, in order to avoid the expensive plan of making a cofferdam, Mr. Barlow, the engineer and designer of the bridge, adopted the more manageable plan of sinking cast-iron boxes. These boxes, which are 12 in number, consist of ½-inch plates, bolted together, each 12 feet in length and 8 feet in width. At low water the workmen excavated in the interior of these boxes, until they got through the treacherous peat, down to the solid gravel—the boxes, of course, following. They were then filled with concrete flush to the top, thus forming a solid foundation for the masonry of the abutment. On the Lambeth shore these boxes, or miniature cofferdams, were not required, there being good gravel a few feet beneath the surface. There are two piers in the river, giving three spans of 280 feet each. Each pier consists of two cylinders 12 feet in diameter (the first ring having been lowered on November 11, 1861). These are sunk to the depth of 16 feet below the bed of the river, 10 feet of which is composed of London clay. The cylinders were then filled with concrete to the depth of 9 feet 6 inches, and a ring of masonry 2 feet 9 inches thick, the whole height, leaving the inside of the cylinder hollow, so that any portion of the work may be repaired at a future time, if necessary. On the top of this masonry are cast-iron bed-plates to receive the towers. These immense towers are of wrought iron, and were made at Messrs. Porter's works, in Staffordshire, were sent off complete, and lifted each in one piece from the barge on to their beds. The roadway consists of two massive longitudinal box girders, which are attached to the vertical bars or suspenders; the cross girders are fixed between these girders at intervals of four feet, and carry plates of three-eighths of an inch in thickness, which are now being riveted, with the addition of longitudinal angle iron, on to the girders. They will then be protected with asphalte, and will receive a covering of about nine inches of roadway metalling. On the outside of the box girders are fixed wrought-iron brackets, four feet apart; these are intended to carry the foot-passenger traffic, and will be plated like the roadway and covered with stone slabs. These footways will be protected with neat lattice-panneled hand-rails. The whole weight of iron-work, inclusive of cylinders, boxes, and the whole of the massive girders for the anchorage of the wire cable, will be about 700 tons. Messrs. J. H. Porter & Co. are the contractors.

COHEN'S COMPRESSED CUMBERLAND LEAD PENCILS.

Everyone who has daily to use a lead pencil appreciates a thoroughly good one. Of late years, the luxury has been denied us. We have tried many sorts, and have found them either metallic, gritty, and indelible, or else rotten and smeary. We tried every sort we heard of, but with one or other of these results, more or less combined. Some of them would work very well for a short time, but suddenly, without warning, our growing confidence was destroyed, and we were obliged to class all in the same category. About a year ago a friend sent us to Newman's, in Soho Square, in order to make trial of Cohen's Compressed Cumberland Lead Pencils. Since then we have used no others. We have given them a long trial. We have used them for outlining perspectives, for rough sketching, and for drawing on wood. In all instances they have answered our wishes. We could desire no better pencils. The points are as firm as the shiny rivals which have been so extensively used, spite of their indelible properties. Their marks are easily and completely rubbed out. Their tone is equal throughout, being made in one single piece instead of in a number of pieces; and—what, however, is a minor consideration with good articles—they are cheap. All the degrees from B B to H H H H are 2*s*. 6*d*. per dozen. The extra degrees, such, for example, as B B B B and 6 H, are 5*s*. a dozen.

Having used them constantly, we are pleased to find a stall erected in the Process Court of the International Exhibition to exhibit them in course of manufacture. We there may now see a man fitting the solid bars of lead into the grooved halves of the pencil, and glueing the other halves to them, binding them tightly together to insure their perfect adhesion, and handing them, when dry, to a fellow-workman, who, with a plane, shoots off the angles and turns out the pencils ready for use. The lead is made from the Borrowdale plumbago; the pencils work freely, with an unequalled smoothness as well as firmness of touch. We recommend our readers to make a trial of them.

A NEW TRIGONOMETER.

Mr. Josiah Lyman, of Lennox, Massachusetts, has invented a new trigonometer. It is said to consist in a combination of the protractor, straight edge, and scale of equal parts. It is to be used in connection with a draughting board which has its sides adjustable. The long side of the semicircular protractor being placed against the edge of the draughting board, the steel ruler may be turned to make any required angle with the edge of the board. The angles are read by a vernier to minutes. A tangent screw and clamp afford facilities for small movements. Upon the ruler slides a scale plate for measuring distances, or for laying them down. There are six scales, representing divisions of 1 inch into 8, 10, 12, 16, 20, and 24 parts. Each has a vernier to tenths, and on most of them smaller parts may be estimated. The edges of the two parts of the sliding rule come down over the edge of the ruler to the surface of the paper, and five marks on these edges make it easy to lay down accurately on the paper the distances indicated on the scales and verniers.

It is said that this instrument affords the means of plotting angles and distances with great accuracy and despatch. The aim has been to make it possible to lay down angles to minutes, and distances to thousandths of an inch. One great advantage of the instrument is that it facilitates the computation of areas in land surveying. When the corners of a field have been plotted, the differences of latitude and the meridian distances can be measured, in a very short time, with an accuracy far greater than that ordinarily used in the field-work of a survey. Great pains have evidently been taken to make the instrument accurate.

It is said that copper containing 24 per cent. of phosphorus will resist a strain of 48,000 lbs. to the square inch.

SHEPHERD'S APPARATUS FOR CLEANSING STEAM BOILERS.

FIG. 1.

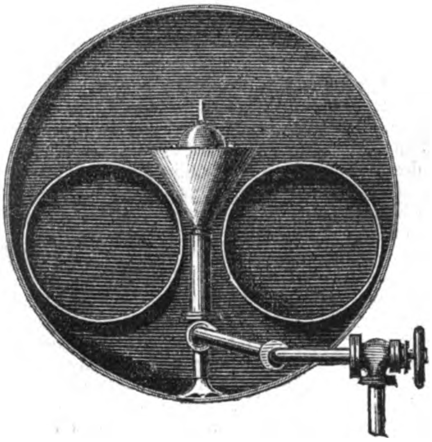


FIG. 2.

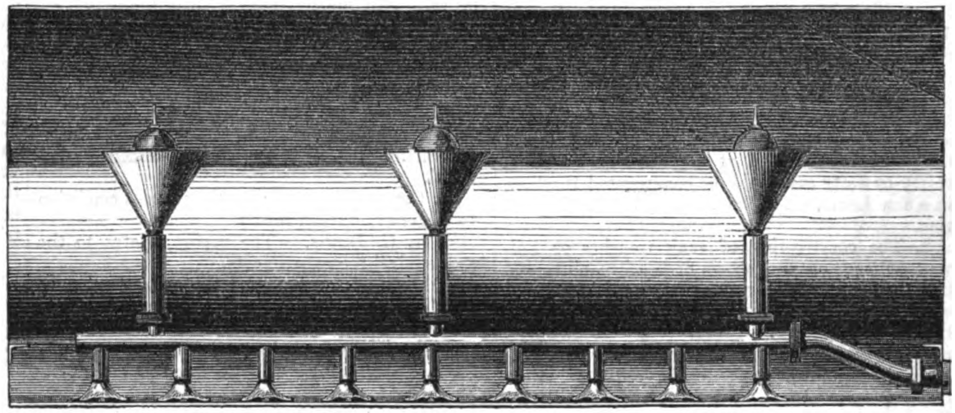

Mr. J. Shepherd, of Manchester, has patented an apparatus for cleansing steam boilers, of which the following is a description:—

In order to collect, carry off, and discharge the sludge, sediment, and scum contained in, and formed upon, the surface of the water in steam boilers, particularly during ebullition, one or more floating receivers are employed, made buoyant by air-tight chambers, balance weights, or other suitable means to render them movable. The floating receivers are adjusted to any given distance below the surface of the water, as may be found desirable, and are connected to the waste pipe or pipes by tubes within each other, similar to a telescope, or by jointing one tube so that it can work in or over another tube, in order that the receivers may rise or fall with the surface of the water, as it varies in height or depth, the collected refuse being discharged from the receivers and waste pipe or pipes by taps, valves, or other suitable means.

In order to expel from the boiler such sludge, sediment, or other matter that may fall to the bottom part of the shell or framework of the boiler, one or more vertical or other shaped pipe or pipes are employed, fitted with a rose, perforated disc, or conical mouthpiece; these pipes, or under sludge extractors, are connected to the main waste pipe, the whole area of the openings into the said main or chief waste pipe to equal but not exceed the area of the said main or chief waste pipe.

These improvements will be clearly understood by referring to the above engravings, in which figs. 1 and 2 are transverse and longitudinal sections of an ordinary steam boiler, having the improvements attached; *a* represents the receivers, of which any number may be employed, according to the length or construction of boiler; *b* a copper sphere or ball, which is secured to the top part of the receiver, and is adjusted to its position according to the distance required for working the receivers under the surface of the water; *c* a taper spout, with a communication through it for admitting the pressure internally to the ball, cylinder, or float, in order to prevent collapse; *d* the waste or main receiving pipe, running longitudinally with the boiler, and terminating as required at the front, back, or sides of the boiler, such termination being fitted with a tap, valve, or other suitable contrivance; *e*, *f*, *g*, are vertical pipes, connected to the longitudinal waste or main pipe *d*, in or over which the receivers, *a*, work.

JONES'S IMPROVEMENTS IN THE MANUFACTURE OF LEAD, TIN, &c.

FIG. 1.

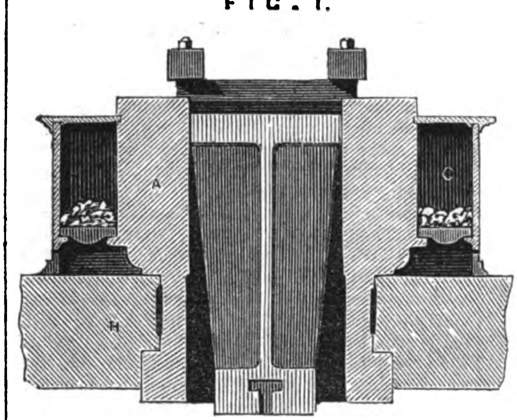

FIG. 2.

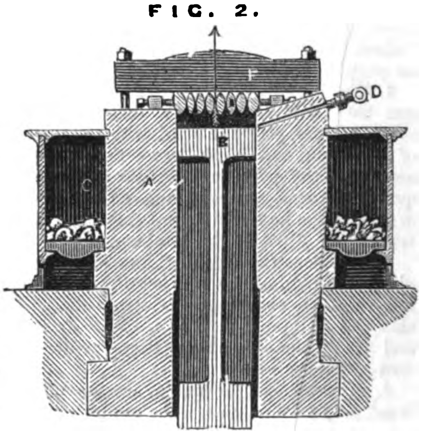


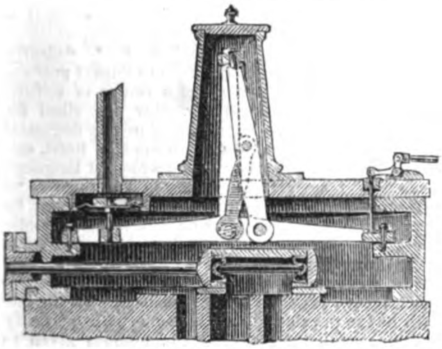
This invention, by Mr. J. Jones, of Liverpool, consists of an improved system for the manufacture of sheets of lead, tin, and other metals, or amalgamation of metals of a like nature, fusible at a low temperature, whereby the sheets can be made of any required thickness or length direct from the metal, or amalgamation of metals, when in a state of fusion, thereby entirely dispensing with the use of rollers, as now commonly practised.

The apparatus consists of a stout cylinder of iron or other suitable metal, heated by surrounding the external vertical side thereof with a fire, or in any other convenient way. This vessel, which is used to contain the molten metal to be converted into sheets, is placed immediately above an hydraulic press, the head of the ram of which forms a piston working within the cylinder, which is used to force out the metal through a die or dies fitted on to the top of the cylinder. These dies may be kept cool by a current or currents of water passing through internal passages formed through them. The sheet or sheets of metal as ejected are received on rollers, and are immediately ready for use. The molten metal for supplying the cylinder is placed above and communicates therewith by a pipe, which is kept heated to cause the metal to flow freely through it. After the piston has forced out the charge contained in the cylinder through the dies, a valve is opened which admits a fresh charge of molten metal from the supply vessel during the down-stroke of the ram, which is again forced out through the forming dies at the upstroke of the ram, as before, and so on until the sheet or sheets have acquired the required length.

In the above engravings, A is a heated vessel for containing the liquid metal to be converted into sheets, and in which works a piston actuated by an hydraulic press placed immediately below; C an enclosed fire-grate surrounding the apparatus, for heating and retaining it at a sufficiently high temperature to keep the metal contained therein in a fluid state; D a valve-plug for closing the orifice used to charge the apparatus with the molten metal, or amalgamation of metals, to be converted into sheets; E the die plates, between the bars of which the metal is forced by the upward action of the piston, the metal becoming solid immediately on coming into contact with the air, where it is received on rollers or in any other convenient way. In some cases, to facilitate the cooling of the sheets of metal, the bars of the die plates are formed hollow, and a current of cold air or water is caused to pass through them, and in some cases a blast or cold air is passed over the die plate and between the sheets of metal as they are delivered from the die. F stout transverse bars bolted to the head of the apparatus for holding the die plates (E) in position; G set screws for regulating the distance between the die bars, which govern the thickness of the sheets to be produced; H the bed plate, upon which the upper portion of the apparatus rests, and which forms the head of the hydraulic press.

A Toulon letter of the 6th states that the building-yards of La Seyne have commenced delivering to the naval authorities the first of the eight iron gun-boats which had been ordered by the State for service in Cochin China. Those small boats, which are made on the most improved model, may be taken to pieces and put together in thirty hours. The machines are of twenty horse-power, and the artillery they carry is one 12-pounder rifled gun in bronze.

BUCHANAN'S SLIDE VALVES.



THIS invention, recently patented by Mr. A. Buchanan, of New Jersey, U.S.A., relates to the combining of the slide valve of a steam engine with a well-known arrangement of mechanism termed the parallel motion, from which it results that the valve is sustained by such mechanism so as to prevent it from being pressed to its seat with a force due to the pressure of the steam, while at the same time it permits the valve to slide back and forth in the required plane, thus greatly reducing the friction and the wear of the surfaces of the valve and valve seat.

The invention also relates to combining with the sliding valve and mechanism, known as the parallel motion, a spring or an equivalent which will yield to the pressure of the steam on the valve, and thereby insure the contact of the face of the valve with its seat, notwithstanding there may be inaccuracies in the parallel motion, and that the parts may wear away and change the adjustments. This yielding property may be contained in the valve itself by making its cover or sides elastic, as represented, or a pressing spring may be applied thereto; or the frame which supports the parallel motion, and is secured to the steam chest in such a manner that it may have a slight play in a vertical direction, is suspended at one end by means of a screw pendent from an elastic diaphragm inserted into the cover of the valve chest. This diaphragm is made of such dimensions that the upward pressure of the steam thereon relieves the valve from a certain portion of the pressure to which it would otherwise be subjected. When it is desired to suspend the action of the diaphragm, steam is let on to its upper surface through a pipe connected with the steam boiler, and which when not used will be closed by a suitable stop-cock.

The invention further relates to the combining with the frame in which the parallel motion mechanism is mounted (and which is contained in the steam chest) a lifting mechanism extending to the outside of the steam chest (consisting of a crank, lever, and rods, or their equivalent) by means of which the valve can be lifted entirely clear of its seat, to prevent the wear of the parts during the working of the engine after the steam has been shut off.

M'INTYRE'S BOMB-SHELLS.

MR. M'INTYRE, of New York, has patented in this country an improvement in bomb-shells and other projectiles, which he describes as follows:—

I cast a hollow case or shell of the size and shape desired with projections from its surface; I then surround this shell with sand, so as to make it the core around which to cast the next shell; and so on. Any number of shells can be formed around each other, the projections sustaining the respective shells firmly in position. These shells are to be filled with powder or inflammable material, so as to explode several times in succession, commencing with the outer casing. To form the shrapnel shell the balls are introduced into the sand forming the core between the inner casing and the next, and are tightly pressed into sand close together, and so remain, after being cast; in other cases, the sand core is shaken out.

M'INTYRE'S BOMB-SHELLS.

FIG. 1.

FIG. 3.

FIG. 2.

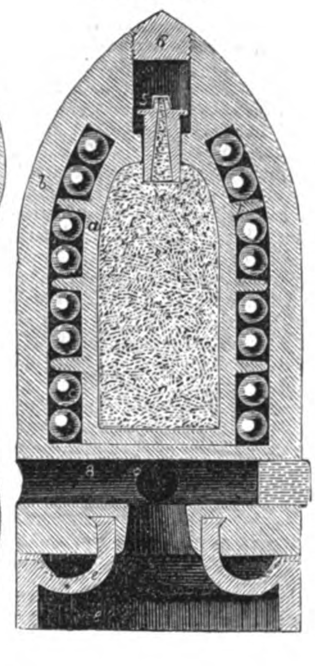


FIG. 6.

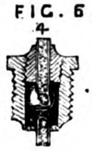

FIG. 5.

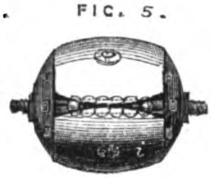

FIG. 4.

My improvements are applicable to globular or to elongated balls or projectiles, and to adapt the same to rifled cannon, I have an expansive metal base corrugated to take the rifling. In order to fire the successive charges I employ a fusee formed by enclosing powder in a lead pipe, and bending the same twice, and compressing the same, and introducing it with sulphur packing into a brass screw cap, so that the confined explosion does not force through this fusee to cause simultaneous explosions. I also employ the same fusee with three or more bombs arranged on an axis, to be rotated and filled within one main bomb. The fusee for the first explosion after being fired may be of any usual kind.

Fig. 1 is a section of a circular bomb with my improvement.
 „ 2 is a vertical section of an elongated shrapnel shell constructed on my plan.
 „ 3 is a globular shrapnel bomb.
 „ 4 is a section of my improvement as applied with grenades in the bomb.
 „ 5 is a side view of said grenades, and
 „ 6 is a section, in larger size, of my improved fusee employed on the inner shells.

Similar marks of reference denote the same parts.

These bomb-shells are to be made of the sizes adapted to fit the various cannon with which they are to be used, and hence in the engraving the various figures may be considered the actual size, or larger or smaller, according to circumstances.

My invention consists in a peculiar manner of casting one shell or casing around another, so that the respective shells are held firmly and correctly in their relative positions. To effect this object I cast the smallest shell first, as at *a*, figs. 1 and 3, and this shell is provided with projections 1, 1, 1. as long as the distance between the one shell and the next; the screw hole for the introduction of the fusee may be cut (as at 2), and then this shell is coated with moulding sand surrounding said projections 1, 1, so as to form the mould around which the next shell (*b*) is to be cast, and so on. Any number of shells may surround each other, and the contraction of the metal in cooling causes the projections 1, 1, to hold the shells firmly to each other and in their correct relative position The sand is easily shaken out after the shells are cast; and in order to introduce balls so as to make the shrapnel fire, I introduce as many balls or pieces of metal as can be pressed into the sand core before casting, hence said balls and pieces of iron are held firmly in place, and the sand surrounding them cannot be shaken out (see figs. 2 and 3); but when the bomb bursts, these balls scatter in every direction with great uniformity. These balls are shown at *c*, *c*, figs. 2 and 3. The various spaces between the shells are to be filled in succession with powder or inflammable material, and a fusee communicating with each causes the same to fire successively, so that there are as many explosions, distinct from each other, as there are charges, and the explosion of the outer charge first throws the shell to a different place each successive explosion.

The first fusee, 3, may be of any ordinary or desired kind, and lighted by the act of firing as usual; but the inner fusees, 4, 4, must be of a different character, because the confining of the explosion would drive the ordinary fusee through, and there would be only one explosion of the separate charges; I therefore form the fusees, as in fig. 6, by taking a piece of fusee in the form of a pipe; I prefer that a small lead pipe be used, and twist the same so that two bends are formed therein; hence a direct line, as in the ordinary fusee, is prevented, and the fire cannot blow through from one charge to the other, but the powder burns the time required, according to the length of fusee. The fusee is to be introduced in the metal screw-cap, as shown, with a packing of sulphur, as at *x*.

The elongated bomb, fig. 2, will be understood in its general construction from the foregoing. I have, however, shown that it is to be fired by a cap on the sliding hammer, 5, that, when the bomb strikes, flies forward with sufficient force to explode it against the screw cap 6. The base of this shrapnel bomb is to have cross holes 8, 8, and I introduce corks in these prior to entering in the gun: I also have a brass or other corrugated metal base *e* attached to the rear end of the bomb, and as the explosion takes place the corrugations are instantly forced out tight against the inside of the cannon to prevent "windage," and the corks in the holes 8, 8, clearing the end of the cannon before the said base *e* are forced out and relieve the pressure, so that the said base *e* is not split

and broken by the action of the gases behind it, and thus the accuracy of the shooting is not impaired by any unequal projection at the back of the ball.

The grenades, *i, i, i,* fig. 4, are attached to the heads 9, 9, with an axis 10; each of these grenades is cast, and the screw for the fusee cut, and the grenades, shown separately in fig. 5, are moulded in the sand together with balls 11, 11, if desired, and then the shell (*a*) is cast around it, and after the sand has been shaken out the grenades can be revolved on their axis, 10, within said shell *a*, by the finger or any instrument introduced through the eye of the shell *a*, and said grenades are charged in succession and fitted with the fusee, 4, 4, and then the whole shell *a* filled with powder, the explosion of which throws the grenades in different directions, and they explode in separate places.

I find that in moulding the balls to form the shrapnel shells, the sand with a small proportion of flour and rosin hold the balls the best in place while the outer shell is cast around; then a small vent-hole should be left for the escape of gases, to be afterwards stopped up. Projections might be made on the insides of the outer shells as well as on the outsides of the inner shells, by moulding in small patterns, or by removing the sand surrounding the shell at places previous to casting.

SERRIN'S APPARATUS FOR STREET LIGHTING BY MEANS OF ELECTRICITY.

Last Tuesday evening Professor Pepper gave an interesting lecture, at the Polytechnic Institution in Regent Street, illustrative of M. V. L. Serrin's apparatus for illuminating streets, &c., by means of the electric light. The inventor was present, and conducted the experiments, all of which were eminently successful, and elicited great applause from a numerous audience. Of course the application of electricity for illuminating purposes is not a new idea or discovery; the difficulty respecting the application of the imponderable has always been, until M. Serrin's invention, to obtain a sustained light. Many years ago the electric light was exhibited; but it was so intermittent, and so liable to pass the spectator from midday brightness to midnight obscurity, that it could not be depended upon. The apparatus invented by M. Serrin is automatic, takes care of itself, and that so well, that, after the battery is charged, the charcoal-points, upon which the light depends, are retained at a calculated distance apart and consumed, the positive to the negative, in the proportion of 22 to 10. To meet the exigencies of this unequal consumption of the charcoal-points, much ingenuity was required. There have been some forty contrivances to produce a sustained electric light; but, until that of M. Serrin, none of them were automatic. The experiments made on Tuesday evening were in every way satisfactory. Wires connected with the battery conducted the light instantaneously to those points of the building where the automatic registers had been fixed. A light was exhibited in one of Defries's prismatic lanterns, supplied for the occasion; another was exhibited through a medium of ground glass. The effect of both was pleasing. To gaze upon the bare electric light is painful to the eye, and would never do for street illumination; but, seen through the media of prisms or ground glass, the eye can behold it with as little discomfort as a candle or gas jet. The bare electric light is penetrative, and may be perceived at many miles distance, which renders it extremely suitable for night signals and telegraphic purposes. The veiled light is not so penetrative, but is more diffused, and, for lighting up cities, more useful. An experiment was made to show how the electric light can be used in an atmosphere of carbonic acid gas, and how even it can be used under water. The latter experiment was perhaps not so decidedly successful as the other, but still it proves that the electric light can be used under water; and if so, it is easy to see what assistance it is likely to be to the diver in his submarine explorations. We shall be able to give more details in a future number. Meanwhile, we may state that M. Serrin has received the medal of the Great Exhibition for his invention, having previously had scientific honours bestowed upon him by various learned bodies and academies of the Continent.

PETROLEUM IN LIVERPOOL.

Petroleum is now being extensively imported into Liverpool, and the attention of the Town Council has been called to the matter, in consequence of certain complaints made by the inhabitants. This week the local functionaries have been engaged in witnessing a series of experiments with the view of testing the combustible properties of petroleum or rock oil, and how it could be most effectually operated upon in case of fire. A temporary brick vault had been erected on some vacant ground in the Police Court, Dale Street, to conduct some of the operations. A cask of Canadian petroleum was first placed in the vault, and after being ignited the fire was extinguished by the application of a fire annihilator; a second cask was also by the same means extinguished, after having burnt for five minutes. A third cask, of thirty-four gallons, was ignited, and when the fire had acquired a certain intensity, two fire-hose were brought into requisition, and a stream of water of considerable power was poured on, which seemed at first to increase, instead of diminish the flames, but in a short time the opposing element conquered. Another experiment was then tried, a barrel of this rock oil being placed on the open ground, and ignited by a train of shavings. On this occasion the oil was allowed to burn for some time, and then an endeavour was made to extinguish it by the agency of water; this, however, was not altogether successful. One of the annihilators was put upon the fire, but could not quench it; but this was afterwards accomplished by water. A barrel of Philadelphia rock oil was then ignited, the barrel being end upwards and laid on the open ground. The flames rose higher than on any preceding experiment, and it was with great difficulty, by the agency of a powerful stream of water, subdued. It is rather singular that none of the barrels should explode, though an opinion was expressed that such an event might be possible.

The result of these experiments has left upon the minds of the town councillors and the other gentlemen who witnessed them, the importance of the question as to the storing of so large a town with such inflammable and dangerous material. It is a serious matter, and one well worth the diligent attention of the public functionaries.

THE STRAIGHT LINE *VERSUS* THE WAVE LINE FOR VESSELS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—As Mr. Moy has now given to his "random remarks," as I think I justly called them, the appearance of an argument, I am afraid it will be thought incumbent on me to refrain no longer from taking notice of them. It is with reluctance, however, I do so, being conscious that I am unworthily occupying the space you can allow me, in assisting anyone in what ought to be the work of self-instruction—his extrication from his own perplexed and tangled ideas. Mr. Moy assumes and presumes too much. He is in a difficulty; he cannot reconcile uniform motion with the action on water of the bow of a vessel moulded with straight lines, and because he cannot himself see any escape from it, he concludes, dismissing all self-reflections, that I am the one who is "profoundly ignorant of the subject" upon which we write. He says that no form of bow will drive the water laterally from a ship's course with uniform velocity, because "the water rising in the form of a bow wave, it is enabled to run down hill towards the sides, which it does at a very irregular velocity" * * * "clearly proving, that the straight line fails to impart uniform motion." In the programme of a course of self-instruction, which doubtless Mr. Moy prescribed for himself, preparatory to his indulging in very dogmatic opinions on such a subject as the one in hand, expressed, as he himself says, "in the strongest language he can use," I am afraid he omitted the theorem of the composition and resolution of forces, and that he skipped an important illustration of it in the parabolic path of a projectile *in vacuo*, where he would have seen an exemplification of a resultant motion compounded from a uniform and an accelerated motion—a case, in fact, parallel, except in causes, with the one which has so puzzled him. Of course it is perfectly compatible with even a variety of motions given to water (among which, doubtless, in actuality are many species of curve lines), that it should at the same time receive either a uniform or an accelerated motion, perpendicular or nearly so to the ship's course, according as her bow is composed of straight or hollow lines; and it is because Mr. Moy does not perceive this, and regards only the actual trajections which the particles of water describe without inquiring into their components, that his advocacy of the wave-line theory amounts, as I have before said, to no more than the throwing out of random inconsiderate remarks, without pertinency or point. I sincerely wish his effort to gainsay this appreciation of it had been successful.

It may perhaps be advisable to append here a few remarks in further explanation, in order to obviate misconception. In the passage of a vessel through water there is an immense amount of motion among its particles, which, though occasioned thereby, is not due immediately to the propulsive action of the bow, and which therefore does not enter as an element into the resistance encountered. The proximate causes thereof are the head of water raised in front and the depression produced at the stern. These give rise to currents and waves, the latter being propagated indefinitely. Now here uniform motion and work (except theoretically in the way of transformation) have no place, and acceleration with momentum under the action of gravity characterise the movements; nor is it to be supposed in regard to the water, which owes its motion primarily to the action of the bow, and contributes to the resistance, that any large portion of it is moved with uniform velocity, for, however convenient it may be to mathematicians to feign that water has the properties of an imaginary discontinuous fluid, such is not the fact. If such, however, were the case, the particles belonging to this particular body of water, being all in a state of isolation, and all being put in motion only by coming into contact with the bow, would all be displaced with uniform velocity. They would now, however, take the character of projectiles, and owe their continued motion to inertia, and would not now be, as in reality they are, the subjects of work—the subjects of continuous pressure, moving only as they are moved, by reason of their opposing a dead resistance instead of that due to their own inertia alone.* The above assumptions of the constitution of water and of the isolated behaviour of its particles, are the postulates of the popular and easy mathematical theory of the subject, and are taken for granted also in the wave-line theory. Let them be admitted, and they peremptorily enforce as a deduction the law of resistance in the exact ratio of the squares of the velocities, and they require it, therefore, to be an inexorably fixed law, and the results determined by it to be invariably certain. But, unfortunately, this mathematical theory and its postulates are not conformable to what we certainly know of the nature and physical constitution of water, nor in regard to the law of resistance is it unfailingly, as it ought to be, in accordance with experimental investigation. There exists, through the influence of pressure and tenacity, or *quasi* viscocity, and other molecular relations, an interaction among the particles of water, and therefore when, because of the acute form of the bow of a vessel, those particles which are in contact with it are coerced into lateral motion, they press upon and urge

* Inertia in this sentence refers in the first instance to that of motion, and in the second to that of rest. And as to *dead* resistance, the contiguity and necessary connection of other particles of water, and the consequent increasing involvement of such in the motion by increase of velocity, are the circumstances which render fluid resistance constant at a given velocity, although such resistance is composed mainly of inertia. And they give to the employment of force, although occupied in conquering inertia alone, the character of *work*, and with as much propriety as when engaged in overcoming friction or gravity.

forward the next, and these again the next, and so on, until the motion is wholly dissipated. It is, accordingly, only the stratum of particles next to a bow (with straight lines) which can be rigorously said to be propelled with a uniform velocity. This stratum is backed up by the resistance of all the others, and this consideration, in connection with the fact that such resistance is constant for the velocity, affords quite sufficient ground on which to base a practical comparative calculation, in terms of the work done, whether as to the case of straight lines or hollow lines, in contradistinction to any *à priori* mathematical deduction from first principles, concerning the impact and resilience of the particles of water, which would involve either a false theory or a problem of impossible solution. We may, indeed, by the more practical method I have adopted, of proceeding by the work done, dismiss from our minds — and, in truth, it would be far better to do so — all consideration of motion in the particles of water, although limited to the first stratum, and regard only the motion of the pressure equivalent to their resultant resistance, whether it be uniform or accelerated, according to the straight or hollow surface of the bow of the vessel. This would put aside all quibbles about the character and direction of the motion of the water, whilst the reasoning as to the respective qualities of the said surfaces would remain precisely the same as before.

I am, sir, yours, &c.,
BENJ. CHEVERTON.

Aug. 11.

MR. CUNNINGHAM'S METHOD OF PROTECTING SCREW-PROPELLERS.

SIR,—The introduction of the mechanical appliance as that patented by Mr. Cunningham, "described in the MECHANICS' MAGAZINE of the 8th inst.," would, if ever adopted, prove to be an additional auxiliary for fouling the screw.

This gentleman must have altogether lost sight of, or forgotten, that there is such a thing existing as sea-weed, which his chain of network would not allow to pass without "permanently" embracing.

The paramount importance of obviating the screw from fouling no one will attempt to dispute; fortunately, however, all such appliances as those patented by Mr. Cunningham can with advantage be dispensed with, simply by constructing screw-propellers with flat circular blades, which would throw off everything coming in contact—an indisputable fact.

Your most obedient servant,
WILLIAM HEWITT.

Bristol, Aug. 8, 1862.

Gossip.

Dr. Robinet has addressed a curious communication on the congelation of water to the Academy of Medicine. It is well known that the blocks of ice formed in the sea yield fresh water by liquefaction. When sea-water or any saline dissolution is congealed, the pure water is separated in the form of ice, and there remains a concentrated watery solution of the saline matter. It is thus salt is economically obtained in the north of Europe. To increase the alcoholic strength of wine it may be subjected to artificial cold, whereby the water alone which it contains is congealed and the wine becomes richer in alcohol. By operating in a similar manner on potable water Dr. Robinet has found that it loses nearly all its salts, whether soluble or not. The waters of the lake of the Bois de Boulogne having been subjected to the operation, the small quantity of calcareous and magnesian salts they contained were eliminated. The purity of the water obtained by this method is such that it may in many cases be used instead of distilled water.

A prospectus has been issued of the Spring Creek Copper Mining Company of South Australia, with a capital of 100,000*l*., in shares of 5*l*. The object is to work the Spring Creek Mine, near Port Augusta, which is a recent discovery. Very flattering statements have been made respecting the richness of the mine.

The British and Foreign Railway Plant Company (limited) has been launched for the purpose of supplying railway plant and stock, both fixed and movable, of every description, for British or foreign railways, both in the way of selling, leasing, and hiring. Both in England and Belgium a number of companies of a similar character are already in profitable operation. The first issue of capital is to consist of 100,000*l*., in 20*l*. shares.

The South Eastern Railway Company have recently added another steamer to their fleet, the Albert Edward. At the trial trip, on the 26th ult., she attained between 16 and 17 knots an hour. She performed the passage between Folkestone, on Tuesday week, a distance of 26 miles, in 93 minutes. This was done with 330 passengers on board, and with a strong south-west wind blowing.

A French company has been formed in Paris, with a capital of 1,000,000*l*., for the cultivation of cotton in Algeria. The company also propose to cultivate other crops, such as corn, olives, vines, tobacco, and flax; and will further breed cattle on a large scale, and likewise propagate the rearing of silkworms, cochineal, and other valuable produce. The land proposed to be cultivated by the company comprises a surface of nearly 26,000 acres.

Mr. W. Bertram, of 26 Guildford Road, Greenwich, writes to say that he took out a patent similar to that ascribed to Mr. Robert Aytoun, in Civilian's letter, on the 18th ult.

In the construction of the Bulah Viaduct, four miles from the town of Brough, in Westmoreland, an ingenious and novel mode of erection was adopted by the contractors, Messrs. Gilkes, Wilson, & Co. They used no scaffold, but having commenced the erection of the first pier from the abutment on the Brough side of the valley, by means of a crane with a gib extending from the abutment, they swung each piece of the iron work of the pier by counterbalancing it with a shifting weight-box as it swung, and thus were enabled to lower it steadily to its place. When the first pier was erected they placed two bulks across from the abutment to the pier, and ran the girder over, dropping it into its place with the assistance of the crane. On the completion of the first span the crane was moved forward, and the other piers were erected and connected by girders in the same manner. By this mode of erection the viaduct was completed in the almost unprecedentedly short time of four months.

We have just heard of a most liberal offer having been made to the Lancashire Relief Fund by an American gentleman (which, of course, was immediately accepted) of the whole profits, equal to 10*s*. upon each article sold, of some most useful household inventions, until the close of the Exhibition in October, and which are shown and explained in the American Department of the International Exhibition daily. This is as it should be, and clearly proves that amongst the better class of Americans the angry feelings expressed by the New York Press do not find a place. From what we are given to understand of the nature and usefulness of the inventions, and their popularity in the United States, where upwards of 20,000 have been sold within a few months, in spite of war, we think it probable that not less than 10,000*l*. will be realised from this source for the Fund!

A Glasgow correspondent says:—"I may remark on the peculiar award to R. Napier & Sons, alluded to in your article last week. It is for drawings and for engines of the Persia shown in the drawings. Now, it is a positive fact that Messrs. Napier did not exhibit any drawings containing the Persia's engines. What they did exhibit was, a drawing of some gunboat engines. Mr. D. Kirdaldy (lately with them) exhibited, on his own account, his beautiful drawing of the Persia in Class XII., and most deservedly got a medal (i.e. one besides that awarded to Messrs. Napier). Mr. K. had a photograph of his drawing of the Persia, beside the gunboat drawing; which may have led to the mistake. I perfectly agree with you that the Persia's engines did not merit a medal — unless it might be for 'workmanship,' which could not be shown in the drawings. It is here a common opinion that it would have been better had there not been awards of medals," &c.

The projected fortifications for the defence of the Bristol Channel and the estuary of the Severn are at once to be erected. On the English side of the Channel, a heavy battery will be erected on the extreme western point of Break Dorvin, a promontory which runs out a considerable distance into the Channel, having a high elevation throughout; the second edifice will be batteries on each side of the Steep Holmes; the third, similar batteries on both sides of the Flat Holmes; and the fourth defence a fort mounting heavy ordnance at Lavernock Point, a promontory just below Penarth Roads. It is said that between these defences a very formidable cross-fire could be maintained. In no case would the ordnance be required to command a greater range than 2,000 yards.

An official report, just published, relative to the inundation of the Middle Level, says, that though these occurrences are rare, they have been found beneficial to the crops in succeeding years. The expenses incident to the disaster already paid and incurred are estimated at from 23,000*l*. to 25,000*l*.; but the past, present, and prospective damages cannot be definitively settled; but the commissioners have determined on exercising their loan powers to the further extent of 40,000*l*. In reference to the future drainage of the Level, Mr. Hawkshaw, C.E., has recommended that for the next twelve or eighteen months, in addition to such drainage as can be obtained through Salter's lode sluice, siphon-pipes should be laid over the recently-constructed coffer-dam, and that nothing should be done as to the erection of a new sluice until the siphons have been fairly tried. The expense of fifteen siphons, with air-pumps, steam-engine, and necessary apparatus, is estimated at from 13,000*l*. to 14,000*l*. Six siphons only have at present been ordered by the engineer, and are expected to be shortly fixed. The necessary legal powers to enable the commissioners to provide for the temporary drainage and for the site of a new sluice or other works, have been obtained by clauses in the Middle Level Drainage Act, passed in the Session which has just closed. On the suggestion and recommendation of Mr. Hawkshaw, Mr. A. G. Lynn has been appointed resident engineer of the works for one year, at a salary of 1,000*l*., as Mr. Hawkshaw has heavy and important works under his charge, both at home and abroad, and will probably not be in England during the autumn. Mr. T. E. Harrison, of the North-Eastern Railway, has also been associated with Mr. Hawkshaw as consulting engineer to the commissioners. It may be added that the fifteen siphons proposed to be erected will have a diameter of 3ft. 6in. each, which will give the water the same scope as it had in the three openings of the ruined sluice.

The experiments at Shoeburyness with shot against iron targets have developed some curious results. The appearance of a conical iron shot after having struck the iron target is like that of a birch broom hollowed in the centre. When the point of the cone strikes the target it is stopped, but the surrounding portions of the shot move forward and slide over the centre as a cone, and thus produce the form described.

A proposal has been made to provide a park for the northern district of the metropolis by the aid of a joint-stock company. An estate of about 450 acres has been secured, and about 200 acres of which are to be set apart for a park, gardens, and ornamental grounds. The surplus land will be let off for building purposes. We need scarcely say we wish the project will issue in a satisfactory realization.

On Friday last the Adriatic, belonging to the Atlantic Royal Mail Company, left the Southampton Docks for an official trial trip, in the presence of the Government contractors. Her saloons are capacious and splendidly fitted up. Her length is 354ft., breadth 50 feet, tonnage 3,700 and 1,300 horse power. The engines are on the diagonal oscillating principle. Cylinders 1,000½ in. in diameter, with 12 ft. stroke piston; diameter of paddle wheel, 41 ft. Her speed was tested at the measured mile in Stoke's Bay. The special objects of the trip were to ascertain the working of her machinery, and the speed attainable under steam only, which averaged in the four runs 14,081, or about 16 statute miles per hour. Pressure of steam, 24lb; revolutions of engines, 15; vacuum, 29; on board 850 tons of coals, 55 tons of water; the draft of water aft, 20 feet, forward, 19ft. 4in. The results of the trial, although blowing a hard gale from the south-west throughout the day, with heavy squalls of rain, must have been highly satisfactory.

The Butterly Company's Codnor Park Iron Works, near Alfreton, Derbyshire, have recently rolled one of the largest wrought-iron plates ever made. Its dimensions are 42ft. long by 7ft. 2in. wide in the middle, and 4ft. 10in. at the ends by 2in. thick, containing 252 superficial feet, and weighing 9 tons. The largest plate in the Exhibition is from these works, containing 163 square feet, being 89ft. less than the above. The process of heating and rolling this giant plate has been successfully executed. Two of these plates are now rolled; they are for a beam pumping engine of 84-inch cylinder, 10ft. stroke, and upwards of 300 horse-power, which is being manufactured at the Butterly Iron Works, near Alfreton, for the Clay Cross Colliery Company.

Mr. Ross, C.E., who was connected with some of the earliest and largest railway works in this country, but more recently with railway enterprises in Canada, where he constructed the great bridge over the St. Lawrence, at Montreal, died on Friday last, at Kensington, aged 58.

A letter from Toulon of July 29, published in the *Gazette du Midi*, states that a naval commission assembled on the previous day on board the iron-cased frigate Gloire to prepare a report on the effect of the apparatus applied to her machinery to increase the power of her steam. The success was decisive; the Gloire, having but half her fires lighted, obtained an increase of mechanical force equal to 30 per cent. This invention will be of immense importance with respect to iron-cased ships, as they cannot carry as much fuel as ordinary ships. The experiment tried on board the Gloire proves that henceforth ships of her class may proceed to sea with less fuel and obtain a greater speed than under the old system. It is proposed to apply this apparatus to all steam-vessels in the French Imperial navy.

Mr. Barnet Blake has suggested, in order to carry out recreations for the members of Mechanics' Institutes during the summer months, that they should consist of cricket, bowls, quoits, foot-races, and other amusements in the open air. If the tastes of the members should be of a more intellectual or scientific character, he advises the carrying out of excursions, for the practical study of botany, geology, entomology, landscape sketching, architecture, antiquities, &c. He also suggests occasional cheap railway trips, visits to museums, &c. Respecting the latter, he says that local museums more commonly fail from the want of an intelligent guide, than from disregard to the information they may afford; and if gentlemen who possessed the ability would undertake to give short explanatory discourses, either in museums or similar objects of interest, to classes of working men from Institutes, many a delightful source of recreation, he thinks, might be gained.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

209. W. Orr. *Improvements in the machinery or apparatus for the manufacture of sugar.* Dated Jan. 27, 1862.

This relates to the "blowing up" of sugar; and the apparatus consists of an open vessel, by preference of a rectangular or circular figure, about 12 ft. by 5, and 4 ft. deep. This vessel is made with curved or sloping ends extending to the bottom. The vessel is constructed with the usual double casing for heating it by steam, or by a heating pipe inside; it is also provided with steam pipes for conveying the steam into the open vessel if required. One of these steam pipes is so arranged as to convey the steam to the lower part of the blow-up to adapt it to the heating of a comparatively small quantity of fluid, whilst the other pipe opens into the blow-up at the upper part. Extending across the blow-up is a horizontal shaft carrying a fast and loose pulley, which is driven from contiguous motive power. This shaft has fitted to it a wheel with floats, similar to an ordinary paddle-wheel; these floats are arranged to shift up and down, so that they may be adjusted to the depth of the liquor in the blow-up. Each float-board of the wheel is provided with a series of adjustable knives or cutters, which are fastened by screws to the floats. As the wheel rotates, the knives divide the lumps of sugar in the liquor, whilst the float-boards put the whole of the fluid into rapid motion by impelling it towards one end of the blow-up, from whence it passes down and along the bottom of the vessel, ascending at the other end. In this way a continuous rotatory current is kept up, and any deposition of the sugar in the blow-up is prevented. *Patent completed.*

210. J. Smith. *Improvements in the construction of covered rollers used in machinery for preparing, roving, spinning, twisting, and doubling fibrous materials.* Dated Jan. 27, 1862.

Here it is proposed to use an iron boss or collar of a peculiar make, the periphery of which is formed conical, or any other shape suitable to cause the expansion of a slit or cut ring, which the inventor terms an expansion ring. This ring is made by hand, or otherwise, and while in this contracted state the cloth and leather covering is placed thereon. It is then placed on the conical or shaped periphery of the boss or roller, which causes the expansion of the ring, and stretches the covering to its full extent. The ring is forced on, and secured in its place by a plate or follower, forced up by a nut screwed on to a thread formed on the end of the pap or bub of the roller. The edges of the covering are further secured by grooves cut in the inner faces of the follower and roller, against the edge of which, as the ring is expanded, the edges of the leather covering are pressed, and thus the edges of the covering are concealed, and a very neat appearance given to the roller when finished. *Patent abandoned.*

211. W. W. Warren. *The purpose of preventing the desecration of the dead, for sanitary purposes, and providing a cheap and inexpensive mode of interment.* Dated Jan. 27, 1862.

This consists in a new application of certain incorporated and adhesive substances, to be used either with or without iron or tiles, for covering coffins, sarcophagi, or other modes of interment, by filling in wholly or partially graves or vaults in which the bodies of deceased persons are entombed by a combination of materials composed of cement, lime, asphaltum, or any other setting or binding mineral cement, in conjunction with ballast, gravel, burnt clay, or other siliceous matter, incorporated so as not to destroy their adhesive setting or binding properties. *Patent abandoned.*

212. T. J. Robotham and N. Hackney. *Improvements in purifying slip, glaze, and other potters' materials.* Dated Jan. 27, 1862.

This consists in causing the slip, glaze, or other potters' materials to pass through a box divided into compartments by partitions, in one end of each of which partitions, holes, or passages are so formed that the materials being fed into a compartment at one end of the box may pass successively through each of the compartments, and the passages are formed at alternate ends of the partitions, so that the materials are caused to pass from end to end of each compartment, and the materials pass away from the bottom of the last compartment through a pipe, in which is a tap to regulate the flow of the materials. In each compartment are placed two or more "horse shoe" electro-magnets, and the magnets are placed so that their poles alternate, and the magnets in all the compartments are worked from one battery, the wires from like poles of the magnets being connected together. *Patent abandoned.*

213. J. List. *Obtaining distances and heights, and distances between distant objects, without computation.* Dated Jan. 28, 1862.

This consists of an instrument made of wood and brass, with hinges to fold into a suitable size for carrying in the pocket. It is opened out in the form of a square, and is provided with two small foresights and a backsight hinged to a movable slide; a stand with a socket connects it to a rifle when piled, or to a common tripod for taking the quantity of an angle. A line of tangent divisions is marked on the sliding part, and also above it on the fixed part; on the other, or lower part, there are proportional divisions, with numbers to indicate at sight the distance of an object. A table of figures is also given to indicate the height or distance between two objects at a distance according to the number of degrees and minutes subtended in the observation; an extended scale is also provided to show more accurately the long distances. *Patent abandoned.*

214. H. H. Treppas. *Improvements in the construction, use, and employment of the kaleidoscope, whereby the images may be secured, copied, or photographed, greatly to the benefit of science, trade, and the arts (to be called "the rilievo-dioscope").* Dated Jan. 28, 1862.

This consists of an object box, which is an open one, allowing the objects to be changed or arranged by the fingers or otherwise. Between the reflecting tube and the object box perforated slides of pasteboard or other material may be made to carry lace or other tissues or fabrics with them, or may be filled with coloured glass, &c., made to pass backwards or forwards wherewith to vary the images. *Patent completed.*

215. S. Smith and T. Smith. *Improvements in the manufacture of cord and twine from mill-spun yarns.* Dated Jan. 28, 1862.

This consists in the making up or manufacturing of cord and twine from mill-spun yarns. These yarns the inventors "toss up," by the fore and after turn in the single threads, by which they produce a more uniform and superior article at a less cost. *Patent abandoned.*

216. J. Haukins. *A new composition or wash to be applied to marine and other steam boilers, to prevent incrustation.* Dated Jan. 28, 1862.

This composition or wash is formed of the following ingredients mixed in manner hereafter stated. The inventor takes spirit of salts (hydrochloric acid) and adds potash and soap makers' alkali. He then adds zinc and continues adding it until the acid becomes neutralised, or until it ceases to boil or effervesce; he allows it to cool and settle, and then decants the clear liquid. This liquid applied with a brush in the interior of boilers effectually prevents incrustation, and at the same time preserves the boilers. *Patent abandoned.*

217. J. Hunt. *An improvement or improvements in the manufacture of gas and other chandeliers.* Dated Jan. 28, 1862.

Here the patentee takes a series of square or angular tubes, and bends them into such forms that when they are symmetrically arranged about a common axis, they form a skeleton or framing of the general figure which it is intended the chandelier shall have. The tubes are fixed together by screwing, brazing, or otherwise, and the chandelier is finished by the addition of ornaments. *Patent completed.*

218. M. A. F. Mennons. *Improvements in engines actuated by heated air or by combinations of air and steam.* (A communication.) Dated Jan. 28, 1862.

The essential feature here is the conversion of the separate pump and driving cylinders into a single body, in which are exerted at the same time the suction and forcing of the cold air supplied to the furnace, and the working power of the heated air proceeding therefrom. *Patent completed.*

219. M. A. F. Mennons. *Improvements in the construction of looms for weaving.* (A communication.) Dated Jan. 28, 1862.

This invention is not described apart from the drawings. *Patent completed.*

220. A. H. Church. *Improvements in the means of preserving stone, brick, slate, wood, cement, stucco, plaster, whitewash, and colour-wash, from the injurious action of atmospheric and other influences; also in the application of colours to the surfaces of stone, brick, slate, wood, cement, stucco, mortar, clay, plaster of paris, plaster, whitewash, and colour-wash; and in the retention of such colours thereon.* Dated Jan. 28, 1862.

The patentee claims: 1. The exclusive use of a solution of silica in water, when preceded or followed by a solution of baryta or strontia in water, that is to say, the successive or consecutive use of such solutions as applied to any of the recited purposes of the invention, according to the processes and after the manner described. 2. The exclusive use of the mixture of a solution of silicate of potash or soda with sulphuric, hydrochloric, or other common and suitable acid (and which mixture may be regarded as an impure solution of silica), preceded or followed by a solution of baryta or strontia, as applied to any of the purposes of the invention. *Patent completed.*

221. C. Culling. *Improvements in fire-arms.* Dated Jan. 28, 1862.

Here a projection is fitted by preference on the under side of the stock, and behind the trigger guard; this projection is formed on a lever or instrument, and is so arranged as to be acted on and pressed inwards by the hand when grasping the stock, and there is a catch or bolt which prevents the trigger releasing the hammer till such catch or bolt is moved away: this is done by the lever on which the projection is formed when it is pressed inwards. There is also another apparatus used which is acted on by pressing the butt end of the fire-arm against the shoulder; this arrangement consists of a sliding rod within the stock, the outer end of which has a button or enlargement upon it which extends somewhat beyond the heel plate, so that the rod is moved inwards when the butt is pressed against the shoulder. The inner end of the rod is arranged to act on another catch or stop, which prevents the trigger acting till it is moved away, and the two apparatus above explained are so combined that the rod of the latter cannot be moved inwards until the projection of the former is depressed, the lever on which the projection is mounted also locking the rod of the second apparatus. *Patent abandoned.*

222. S. C. Liston and J. Warburton. *Improvements in preparing cotton for spinning.* Dated Jan. 28, 1862.

According to this invention, cotton is first passed through a scutching, beating, or other machine, acting in like manner to knock out the dirt, and to open the fibre; but in place of making the laps of cotton by such machines suitable for a carding engine, they are made of proper width and thickness for a combing machine. The cotton is then either taken directly to a combing machine and combed, or before being combed it is subjected to a screw gill or other drawing machine and then combed. *Patent completed.*

223. C. H. and E. Morgen. *Improvements in carriages.* Dated Jan. 28, 1862.

The peculiarity of this consists in arranging the apparatus by which the head of the carriage is opened and closed so that the coachman or other person on the driving seat may, by pressing a lever or suitable instrument, cause the head or the parts of the head of a carriage to open and shut. *Patent completed.*

224. G. Chapman. *Improvements in rotating circular knitting frames.* Dated Jan. 28, 1862.

This consists in applying to circular rotating knitting frames apparatus suitable for doubling yarns or threads, at the same time that the knitting machinery is producing its work, and for delivering such doubled thread to the needles of the knitting frame. *Patent abandoned.*

225. G. I. N. de Ridder. *Improvements in railway carriages for the conveyance of travellers and goods.* Dated Jan. 28, 1862.

This consists, 1, in constructing the main framing of T or I shaped or other suitable girder-sectioned wrought iron beams, in lieu of timber beams. The longitudinal beams or framing may be either straight or curved edgeways over the axle bearings, the chief object of the latter form being to enable much larger running wheels to be used in vehicles of this description than has before been found practicable, say from 4½ to 6 feet in diameter, whereby the draught is greatly facilitated. The floor of the carriage when supported on these large wheels, is raised at the parts immediately above the axles, and the upper half of each wheel is enclosed in a box or casing formed in the interior of the carriage or wagon. 2, in the application of an oil reservoir to the journal of the axle, so that the journal shall always be entirely immersed in oil. *Patent abandoned.*

226. W. E. Newton. *Improvements in engines to be employed for pumping or forcing air or water, or for other purposes where a rectilinear motion is required.* (A communication.) Dated Jan. 28, 1862.

This invention consists mainly in a mode of arranging and working the valve gear of the steam cylinders, whereby when one piston is at mid or half stroke, the other piston shall be at the end of its stroke. *Patent completed.*

227. W. Irlam. *Improvements in the construction of railway crossings and turntables.* Dated Jan. 28, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

228. R. Bodmer and W. Wilson. *Improvements in the process of manufacturing artificial stones, parts of which improvements are also applicable to the manufacture of artificial fuel.* Dated Jan. 28, 1862.

The patentees claim, 1, the application and use of sal ammoniac, or other salts of ammonia, in the manufacture of artificial stone or bricks, made according to the process described in the specification of L. D. Owen's patent (No. 1,270), dated the 28th day of May, 1856. 2. The manufacture and

use of artificial stones or bricks entirely of hydraulic or other limes, or of a combination of different varieties of lime, for the purposes described. 3. The manufacture and use of artificial stones or bricks of a black or dark colour, either for building purposes or for fuel, as described. 4. The application and use of sal ammoniac, or other salts of ammonia, in the manufacture of artificial stones or bricks, made entirely of hydraulic or other limes, or of a combination of different varieties of lime, or in the composition of which natural or artificial calcareous cements are employed. *Patent completed.*

229. J. H. BRIERLY. *A clasp or fastener for reversible belts, bands, or straps.* Dated Jan. 29, 1862.

In carrying out the invention the patentee employs two plates of metal, or any other material similar to those used for the clasp, generally understood by those connected with the trade as a double clasp, which consists of two clasps connected together, when worn on the person, by a hook on the one and an eye on the other. To the back of each plate of metal or other material he attaches a metal wire bar of suitable width; he also further forms out of the plate of metal or other material, or attaches to it, two hooks, one on each side, the part usually having but one, but so arranged that neither of the hooks can be seen when worn on the person; to the other plate of metal or other material, or part of the double clasp usually containing the eye or slot, he attaches a projecting piece of metal, having a groove or slot cut or formed in it for the purpose of receiving a sliding bar, wider at each end than in the centre portion, and having an eye at each end so formed that the eye will receive either of the hooks attached to the other portion of the clasp, so that, by moving the sliding bar, the double reversible clasp may be connected from either side at pleasure, and, having attached the double reversible clasp to a belt, band, or strap, made of leather and silk on the one side and leather only on the other side, the belt, band, or strap may be connected and worn either side outwards, according to the wearer's choice. *Patent completed.*

230. T. CLAYTON and W. SMITH. *An improved flyer.* Dated Jan. 29, 1862.

According to this invention, instead of the yarn being guided through the tube of the flyer direct on to the bobbin, the inventors guide it to the bottom of one arm of the flyer, so that it will be wound on the bobbin more evenly, and prevent snarls, so common on the ordinary plan. They accomplish this object by fixing a washer on the top of the flyer, and a cross piece on the top of the tube, with a guide or guides. *Patent abandoned.*

231. T. D. DE BOUTTEVILLE. *Improvements in machinery applicable to the spinning of fibrous substances.* Dated Jan. 29, 1862.

This invention has for its object the prevention of the loss of time consequent upon stopping the ordinary drawing and doubling machine for the purpose of changing the can when the machine is driven at great speed. For this purpose the head of the machine is similar to that in ordinary machines, except that, instead of being fixed as usual, it is capable of being turned on a pivot, when one of the cases is full, either from right to left or from left to right, according to its position over the empty can, which is at the side of the full can, and turns in the same direction with it. The movement of the head is controlled by a stop in such a manner that no time is lost in the taking up and delivery of the cotton or other fibrous substance. This stop, pressed upon by a spring, holds the head sometimes to the right, sometimes to the left, but it is raised at the required moment for changing the can by means of a bent lever, when the head is pushed into the position required. *Patent completed.*

232. L. A. PULVE. *Improvements in fireproof iron chests and strong boxes.* Dated Jan. 29, 1862.

These improved iron chests or safes will be composed of a double casing on all sides. Each side of the first casing will be formed of two sheets of iron, with counter-sunk rivets on to an iron framing, the thickness of which will be regulated by the space which it is desired to reserve between the two sheets of iron. The outer door which closes the safe will precisely resemble the sides, and will turn on a pivot top and bottom. To preserve the chest, and make it fireproof, the inventor proposes to introduce between the two sheets of iron a fireproof body, composed of very refractory siliceous sand; and to strengthen it, he proposes to place fillets or bands of iron on all the outer angles of the chest. The inner casing will be constructed in the same manner, and of similar material as the outer, the space left between the two sheets of iron being the same, but, in this case, stuffed full of raw wool, which will render the interior still more inaccessible to heat. *Patent abandoned.*

233. J. M'KEAN and J. GARBOTT. *Improvements in sizing or dressing yarn or textile materials.* Dated Jan. 29, 1862.

This invention relates to the application or the employment and use of a new composition to be used for what is technically known as sizing, or dressing and preparing warp-yarns for the loom, so as to enable such warp-yarns to undergo the process of weaving. The basis of the new composition consists of luminous and siliceous earths and compounds, such, for example, as that known as kaolin, or china clay, or any suitable siliceous or aluminous matter, mixed with certain mucilaginous and glutinous extracts obtained from materials such as linseed and the refuse clippings of hides. *Patent completed.*

234. T. MERITON. *Improvements in marine and other boilers for generating steam.* Dated Jan. 29, 1862.

This invention consists, chiefly, in so constructing these boilers that the patentee is enabled to introduce at the back of the fire-grate, in the part usually known as the "up-take," a series of vertical or inclined tubes, of a circular, oval, or any other convenient form, connecting the water space at the top of the boiler with the water space at the bottom of the boiler, behind the bridge at the back of the grate, and thereby materially increasing the heating surface, and the consequent evaporative efficiency of the steam-boiler. At the same time, by the improved arrangement he is enabled to render all the tubes and parts of the boiler more accessible for the purpose of repairs and cleaning or clearing operations than any other form of boiler hitherto used. The important advantages of these improvements are the facility with which boilers constructed upon this principle may be thoroughly repaired, and the parts most subject to wear renewed, without laying up the vessel for any length of time, as is necessitated with all other descriptions of boilers in use. *Patent completed.*

235. W. CLARK. *Improvements in the disintegration and bleaching of textile materials for the manufacture of paper.* (A communication.) Dated Jan. 29, 1862.

The improved process, the subject of this invention, requires but an almost inappreciable extra expense of working, as all existing manufacturers may be employed for the production of a white paper from all kinds of straw. The patentee employs straw prepared as in ordinary in the manufacture of wrapping or brown paper from straw, which consists in steeping the straw in a bath of lime water. After this is withdrawn, it is allowed to ferment, or, better still, it is heated by a jet of steam. He then takes the straw, after treatment in the lime bath, and disintegrates it by passing it between crushing cylinders. After this he places it in a vat, furnished at the lower part with a false bottom of wood, covered with a layer of straw or broom, which will allow of the filtration of the bleaching waters. One or more cocks are placed at the bottom of the vat, of different sizes for regulating the flow of the liquids. The vat being filled, he allows the matters to drip, and he then waters it sufficiently on the top by a rose or other distributor, with water acidulated with sulphuric acid, marking about one degree. *Patent completed.*

236. J. B. HARBY. *Improvements in preserving electric telegraph cables and wire.* Dated Jan. 29, 1862.

This invention consists in impregnating or coating the yarn or textile fabric or fibres employed in the manufacture of electric telegraph cables with a composition of solution of caoutchouc, resin, and powdered chalk, the proportions of the materials being varied according to the pliability required when the composition is set. In some cases the patentee mixes with the composition arsenic or other poison, to guard against the attacks of fish, insects, and animals. The invention also consists in coating the conducting wires, whether in submarine, subterranean, or suspended telegraphs, as also complete cables and the separate wires composing the cable, with the said composition, which he applies in a heated state. The suitable proportions of the materials forming the composition are as follow. — caoutchouc 1 part, resin $3\frac{1}{4}$ parts, chalk $3\frac{1}{4}$ parts, arsenic $\frac{1}{10}$th part. *Patent completed.*

237. R. A. BROOMAN. *Improvements in machinery for puddling metal.* (A communication.) Dated Jan. 29, 1862.

The object of this invention is the substitution of mechanical for manual power for stirring up the metal submitted to the action of the fire in reverberatory furnaces. The invention, as applied to the puddling of iron, is as follows:— The machinery employed is intended to stir up the metal at the bottom of the furnace by means of tools such as puddlers, stirrers, and other equivalent instruments introduced into the furnace through openings formed in the most suitable parts of the furnace. The tool is worked in all parts of the metal in quite as varied a manner as if by the hands of a workman. The speed of the tool is regulated at the will of the attendant, by shifting the driving-band on the driving pulleys of the machine (also its position and the direction of the oscillations on the surface of the bed) so that the puddling is not only effected without labour, but in less time than in the ordinary manner. *Patent abandoned.*

238. B. FOSTER. *Improvements in machinery or apparatus for spinning and doubling wool and other fibrous materials.* Dated Jan. 29, 1862.

This invention relates to those spinning and doubling machines in which a cap or bell is employed, and has for its object the prevention of snarls. For this purpose the patentee connects levers or similar apparatus to the bobbins, whereby they may be raised so as to cause them to pass into the caps or bells of these levers, or other such apparatus are combined with that commonly employed for shifting the driving strap, so that the two operations may be effected simultaneously. *Patent completed.*

239. W. E. NEWTON. *Improvements in printing machinery.* (A communication.) Dated Jan. 29, 1862.

This invention of improvements in printing machinery relates: 1. To improvements in that description of printing machinery in which the type or printing surface is curved for the purpose of being secured on a cylinder or curved surface. 2. To improvements in printing machinery in which the type or printing surface is flat, as in the ordinary forms. The first improvement relates to an improved mode of securing stereotype plates or other analogous printing surfaces on the type cylinders or rollers of rotary printing machines. For this purpose, stereotype castings of type have heretofore been mounted on wooden or other blocks, and secured in iron frames, forms, or chases, which were fastened in any convenient manner on to the type cylinder or roller. The present improvement is adapted for securing stereotype plates, or any other solid printing plate or surface, on the type cylinder, and consists in attaching or securing the stereotype or other plate or printing surface direct on the cylinder by means of strong metal fingers or cramps, the stems of which are screwed and pass through holes made in the face of the cylinder, and are secured and held down from behind by means of fly nuts, thumb screws, or other equivalent contrivance. By this means the blocks and iron frames for holding the stereotype plates are dispensed with. The second improvement relates to a novel construction of perfecting machine. In this machine there are two impression cylinders, and two type cylinders, with the necessary inking arrangements adapted to each type cylinder. There are also two feeding boards, on each of which is placed a pile of paper ready to be fed into the machine in the ordinary manner by the feeding boys, who push the paper down sheet by sheet to a gauge point, and place the edge or margin of the sheet under carrying in rollers, which descend alternately and take hold of the paper and conduct it in between a pair of feeding rollers provided with tapes, which carry the sheets to be printed down to the impression cylinders. *Patent completed.*

240. W. E. NEWTON. *Improvements in the boxes for the journals of railroad carriages and other axles.* (A communication.) Dated Jan. 29, 1862.

This invention consists: 1. In providing in journal boxes an endless revolving belt or ring for the purpose of sustaining the weight bearing on railroad carriage axles, and reducing the friction on the axles produced by the weight supported, and likewise for elevating the lubricating or cooling material, which may be water or other liquid, from the bottom of the journal box to the upper side of the axle journal, and further, under certain circumstances, for the purpose of forming a spring cushion above the axle journals. 2. It consists in supporting in the journal box the endless belt or ring by means of a combination of a pin sleeve and sheave, or simply by means of a series of friction rollers or balls interposed between the shell of the journal box and the belt or ring. 3. It consists in the employment of an auxiliary box for steadying the end of the journal sidewise and endwise, and also for lubricating the end of the journal. 4. It consists in making the journal box with a longitudinal partition, and thus forming a separate chamber for containing the lubricating material and cotton waste which lubricates the axial pin of the sheave. *Patent completed.*

241. G. BEDSON. *Improvements in wire fences.* Dated Jan. 29, 1862.

This invention consists in so forming and adjusting wire fences that their section taken vertically shall be greater than that taken horizontally, and the inventor therefore uses flat or oval wire either in simple or combined strands. *Patent abandoned.*

242. M. COLLIER. *Improvements in looms for weaving.* Dated Jan. 29, 1862.

This invention is not described apart from the drawings. *Patent completed.*

243. G. and G. PHILLIPS. *Improvements in the distillation and rectification of alcohols or spirits.* Dated Jan. 30, 1862.

This consists in the filtration of the vapour of alcohol or spirit by passing it through wire gauze, perforated sheets of metal, shavings, filings, or pellets of metal, fibres of silk, cotton, wool, &c., arranged so as to have fine openings or passages through which the vapour of alcohol can pass, but not its impurities. *Patent completed.*

244. M. ALLEN. *Improvements in the construction of buildings for the prevention of fire, and in the materials to be employed therein and therefor.* Dated Jan. 30, 1862.

Here the patentee economises the space which the staircases usually occupy, and renders the building fireproof by dividing or insulating the staircases from the building of which they form a part. He forms a material for building purposes by the combination of cinders, slags, cokes, culm, clinkers, or other calcined substances of similar character, with Portland or other cement. *Patent completed.*

245. J. GOUTARD. *Improved truss plates, producing an upward pressure.* Dated Jan. 30, 1862.

This consists in a mode of fitting the metallic plate, on which is fixed the cushion intended to squeeze the hernia. The said plate is made of steel, and in two parts, which are joined together as a hinge; the flattened end of the hinge peg is fastened to the usual curled spring girdling the body. Both parts of the plate have corresponding notches cut in the hinge part, and a small fluted cylinder, fixed by a pin on the hinge peg, is lodged in the notches. On one of the two parts of the metallic plate a small tempered steel plate is fastened, either by a screw or rivet; the end of the said blade enters the fluting of the small cylinder, which is in the same line; if now the portion of the plate carrying the steel blade acting as a spring is wound around the hinge peg, the blade of flexible steel yielding, it gets out of the fluting where it was engaged to fall back in the next one, and to maintain the said plate either in the plane or angular position, as the case requires. *Patent completed.*

246. E. H. RIPPINGILLE. *Improvements in engines worked by steam or other fluid and in pumps.* Dated Jan. 30, 1862.

This applies to those steam engines wherein the injection water, on its way to the condenser, is caused to enter a cylinder, and to act on a piston working therein, so that the power obtained thereby may be rendered available in the working of the engine. The invention consists, 1, in applying an elastic piston in the injection cylinder or engine to prevent concussion at the termination of the stroke, and also during the covering of the port by the valve. 2, in applying a chamber or vessel to the condenser, so that the injection water from the injection cylinder or engine shall be first received into such chamber or vessel, and then be by it delivered continuously in numerous streams or jets into the condenser, the chamber or vessel being of such capacity, and so arranged, as to contain sufficient water to keep up a supply to the condenser during one half stroke of the piston in the injecting cylinder. 3, in applying apparatus for refrigerating the condensed water from a steam engine in combination with an injecting cylinder or engine. 4, in a combined arrangement of air pump and injection cylinder or engine (by which the air is withdrawn from, and injection water is supplied to, the condenser), with a water pump for withdrawing the condensed water and condensed steam from the condenser. 5, in a mode of constructing steam-engine condensers. *Patent completed.*

247. J. FIRTH. *An improvement in finishing mohair cloth.* Dated Jan. 30, 1862.

Here the cloth is first woven in the ordinary manner, and the pile is then raised to a longitudinal or straight direction by the "gig mill" or other apparatus, frequently reversing the wool or pile, and it is afterwards raised in a transverse or lateral direction. The cloth is next boiled or steamed to give it a lustre, and it is then dyed and tentered in the usual way. The centre or border (or both) is then printed, and the pile re-raised, and the piece tentered, carded, and batted with sticks or rods, so as to produce a fur finish all over the piece. The fur is then cut down to a velvet pile where required, leaving the fur pile its original length at the other parts. *Patent completed.*

248. H. ROBOTTOM and R. UNDERWOOD. *Improvements in watches and pocket chronometers.* Dated Jan. 30, 1862.

This invention consists in a method of constructing watches and pocket chronometers, so that they may be wound up and the hands "set" without requiring a key or other separate instrument for the purpose. *Patent abandoned.*

249. W. DAVIES. *Improvements in apparatus for cutting cork and bungs.* Dated Jan. 30, 1862.

This invention is not described apart from the drawings. *Patent completed.*

250. W. CLARK. *Improvements in mechanical wrenches.* (A communication.) Dated Jan. 30, 1862.

This relates to self-acting wrenches for screwing and unscrewing nuts of circular, hexagonal, or other form, and of any dimensions, which wrenches are an improvement on what is known as the "Clyburn wrench." This wrench is formed with two jaws, one being fixed and the other opening from, or closing on, the part to be held, by turning the handle in one or other direction, so that the jaws may grip tubes or nuts of different dimensions, while the more difficult the nuts are to turn the greater is the force applied for pressing the handles together, and compressing the nut between the jaws, and, as the wrench cannot slip, the nut is forcibly turned. *Patent completed.*

251. A. C. B. MALOIS. *Improvements in mechanical fabrication of boot and shoe heels.* Dated Jan. 30, 1862.

These boot and shoe heels are formed of one and the same piece of leather, suitably shaped by a spherical machine, which stamps it so as to force the edges of the leather to fold over on themselves, so as to form the shell or frame of the

heel, which is afterwards filled up with discs of leather in order to complete it. *Patent abandoned.*

252. A. Larousse. *Improvements in the manufacture of wheels for wagons, locomotive engines, and other vehicles used for railway purposes.* Dated Jan. 30, 1862.

The main object here is the so making of the skeletons or centres of railway wheels that they shall possess the advantages of the wrought wheel without the great expense attendant on its manufacture. This the patentee effects by locking the inner edges of discs, when these are used as substitutes for spokes, into a wrought boss by enveloping them in the wrought metal, whereby he dispenses with the necessity for raising the sp. kes to a welding heat. *Patent completed.*

253. D. Littlehales. *An improved plastic compound as a substitute for papier maché.* Dated Jan. 31, 1862.

Here the patentee takes oatmeal, flour, pea, bean, barley, or linseed meal, which he mixes with tar or other varnish until it becomes of a thick pasty consistence, and he then moulds it in dies or forms it into sheets as required, then dries it in an ordinary japanner's stove. When dry and hard he saturates it with linseed, or other suitable oil, and afterwards finishes it with varnish, or colours it, in the usual way articles of papier maché are coloured. *Patent completed.*

254. H. White. *Improvements in collars.* Dated Jan. 31, 1862.

This invention is not described apart from the drawings. *Patent completed.*

255. J. Silvester. *Improvements in pocket and other spring balances.* Dated Jan. 31, 1862.

Here the helical or coiled spring of the balance is connected at top with a loop, by which the balance is suspended. The cylindrical case surrounding the spring is fastened at bottom to the bottom of the spring, and the hook on which the article to be weighed is supported is fixed to the outer side of the bottom of the case. The loop carries a graduated or index plate, which is situated outside the case, and on the top of the case an index finger or pointer. When an article to be weighed is hung on the balance, the case is pulled downwards, the upper part of the spring being exposed; the index finger traverses the graduated index, and indicates thereon the weight of the article. The invention also consists in constructing pocket and other spring balances, as follows:—The helical or coiled spring is without a case, a loop and ring being fixed at the top, and a second loop and hook at the bottom of the spring. An index plate is fixed to the top loop, over which index plate another plate, connected with the lower end of the spring, slides, covering the index plate. When any article is hung on the balance, and the spring elongated, the covering plate descends in front of the index plate, and uncovers that part of the said index plate which indicates the weight of the article. Or the weight may be indicated by a pointer or otherwise. *Patent abandoned.*

256. F. Baggett and J. Sanger. *An improvement or improvements in breech-loading small arms.* Dated Jan. 31, 1862.

This invention (the details of which we cannot give space to here) consists in a method of constructing the breech ends of breech-loading small arms, and parts connected therewith, for opening and securely closing the breech. *Patent abandoned.*

257. H. Schatten. *Improvements in the manufacture or construction of gas meters.* Dated Jan. 31, 1862.

This invention is not described apart from the drawings. *Patent completed.*

258. J. Dodge. *Improvements in C springs for carriages when used without a perch.* Dated Jan. 31, 1862.

The object of this invention is to insure the axles of carriages in which C springs are used without a perch being retained in their proper position, and thereby to prevent the irregular running or "wabbling" of the wheels. The invention consists in applying two parallel rods by means of a clip on the axle, and through a brace or braces to the free end of the C spring; the opposite ends of the parallel rods may be attached to the body of the carriage, or may be otherwise attached. *Patent completed.*

259. W. Walton and F. Walton. *Improvements in the manufacture of wire cards.* Dated Jan. 31, 1862.

This consists in the use of a solution of the semi-resinous substance prepared from drying oils by their being oxidised for cementing and coating fabrics in a suitable manner, to render them fit for the backs of wire cards. Backs of wire cards, composed of woven fabrics cemented and coated by the above flexible cement, will be found to resist the action of grease, oil, and moisture. Small quantities of india-rubber or gutta-percha may be combined with the solution above mentioned. *Patent completed.*

260. G. Mehrtens. *Improvements in ladies' stays, and in the bodies of ladies' dresses.* Dated Jan. 31, 1862.

These stays are formed of three pieces, one piece forming the front of the stays, and the two other pieces forming the back thereof, each portion being stiffened as usual. The front portion is slit at two points corresponding with the breasts; these slits are connected together by an elastic lacing or diagonal strapping of elastic web. The back parts of the stays are similarly slit, and laced or strapped at points corresponding with the blade bones. The back and front of the stays are fastened in the usual way. *Patent abandoned.*

261. J. Hargreaves. *Improvements in the manufacture of pipes or tubes for conveying water, gas, acids, sewage, enclosing electric telegraph wires, and for other purposes, which improvements are also applicable to the manufacture of other vessels and articles, and in the machinery or apparatus connected therewith.* Dated Jan. 31, 1862.

This consists: 1. In combining and treating various materials or substances which the inventor converts into a bituminous mastic possessing density, ductility, hardness, great strength to resist pressure, and other qualities. Bitumen, cement, chalk, clay, flint, lime, oyster and other marine shells, river or other sand, slag and slate, he uses, and utilises the refuse and short waste of cotton, worsted, wool, hemp, flax, tow, jute, cocoa-nut fibre, and other fibrous materials, gutta-percha, caoutchouc, gums, and oils. *Patent abandoned.*

262. P. Schewweghs and A. J. H. De Boisserolle. *Certain improvements in treating fatty and oily matters for obtaining their acidification, and in the apparatus employed therein.* Dated Jan. 31, 1862.

Here the patentees effect the acidification by the simultaneous employment, while in a hot state, of both sulphuric and nitric acids. *Patent completed.*

263. C. Pontifex, Jun. *Improvements in apparatus for cooling or heating fluids or liquids.* Dated Jan. 31, 1862.

This consists in the arrangement and application of a hollow disc, or a series of hollow discs or cases of circular or other forms, with or without the addition of a division plate therein, such cases being contained in a conical or other shaped vessel, placed in a horizontal or vertical position; cold or heated fluid or liquid enters the apparatus at either end of a central connecting pipe or passage, and after passing through the series of discs or cases, it is discharged at the opposite end of the central pipe or passage. These discs or cases are supported within a conical or other shaped vessel, and the fluid or liquid to be cooled or heated is passed through the containing vessel, and through openings formed through the discs or cases, until the required temperature is obtained. *Patent abandoned.*

264. E. H. C. Monckton. *Improvements in the application of electricity for obtaining ammonia, and other useful products, during the combustion of coal and fuel, and in the apparatus employed therein.* Dated Jan. 31, 1862.

The object here is to obtain ammonia and other useful products directly from the atmosphere and other sources by a continual electrical process from the commencement, by which means smoke is prevented and fuel economised. The process is firstly to form what the patentee terms an electrical bath, by applying the electrical current however generated, and with or without the use of induction or tension coils or Leyden jars, or substitutes for Leyden jars, such as the condensers of electricity attached to tension coils, to natural and artificial graphite and plumbago, and also to the coal and fuel in ordinary furnaces of all descriptions. *Patent completed.*

265. T. Stephens. *Improvements in the manufacture of book markers.* Dated Jan. 31, 1862.

This consists in manufacturing book markers by machinery for weaving ribbons, and in producing figures, designs, and mottoes thereon of various descriptions of colours. *Patent abandoned.*

266. J. Gibbins. *An improved composition for coating wood, metal, and other materials.* Dated Jan. 31, 1862.

Here the inventor adds to boiled linseed oil, while it is at a high temperature, oxides of lead, arsenic, caoutchouc in solution, borax and gum copal, in solution; and at a lower temperature he adds to the above mixture sulphur and spirits of turpentine. During the process of admixture the ingredients should be stirred together. *Patent abandoned.*

267. A. Forsyth. *Improvements in the manufacture of frames and in tablets used for advertising purposes.* Dated Jan. 31, 1862.

Under one modification for producing frames which are particularly suitable for the display of show cards or trade announcements at railway stations, &c., the frame is made of cast iron. The metal is run into a suitable mould, and the frame may be coloured, gilded, or otherwise ornamented. *Patent abandoned.*

268. C. Veronique. *An improved wrapper garment.* Dated Jan. 31, 1862.

This consists in the production of a garment which can be used as a railway rug or wrapper, and also capable of being easily convertible into a morning gown. *Patent abandoned.*

269. W. Smith. *Improvements in machinery for the manufacture of bricks, tiles, or other articles of a similar nature or character.* Dated Feb. 1, 1862.

The patentee claims: 1. The revolving cylinder and combination of parts for pressing the clay or other plastic materials into the moulds as described. 2. The ram and spring and combination of parts for resisting the action of the clay or other plastic material whilst the mould is being filled as described. 3. The block or blocks for pressing the clay into the moulds as described. 4. The steam cylinders and combination of parts for pressing the clay or other plastic material in manner described. 5. The apparatus and combination of parts for receiving and removing the bricks after leaving the mould as described. *Patent completed.*

270. L. Fauvel. *Improvements in apparatus for indicating the existence of escapes in gas-tubing, and for stopping the continuance thereof.* Dated Feb. 1, 1862.

This consists in providing either the gas meter or the tubing itself with an apparatus which is put into action by the gas passing through the meter, or through that part of the tubing where the apparatus is situated, thereby causing a wheel provided with proper projections or pins to revolve and act with the said pins against the end of a hammer, and make this latter strike an alarum. *Patent completed.*

271. R. Burkhardt and C. Doebler. *Improvements in Æolian harps.* Dated Feb. 1, 1862.

Here the strings or wires, instead of being placed on a flat board, are placed on a hollow sounding board, formed of a wedge shape, and fixed to a spindle supported on any suitable framework. Near the sides of the sounding board are placed curved wind conductors, which collect a large quantity of wind, and concentrate it upon the strings or wires, after which it escapes through a narrow passage on each side. The collection and concentration of a large quantity of wind, combined with the draught, cause a great increase of sound, and thereby produce a more pleasing and efficient instrument than heretofore obtained. The hollow sounding board is placed on a spindle to allow it to turn and catch the wind at any point of the compass. *Patent abandoned.*

272. J. Pendlebury. *Improvements in the method of, and apparatus for, lubricating steam-engine cylinders, slides, and other surfaces.* Dated Feb. 1, 1862.

This invention is carried into effect as follows:—Near the bottom of the steam cylinders the inventor connects a pipe, having at the top a small vertical cylinder, at the upper part of which is the cup for holding the tallow, oil, &c. In the interior of the small cylinder there is a double piston with a plug between them, which is hollowed in a concave form. The interior of the small cylinder is in communication with the steam cylinder by means of tubes or pipes. When the piston is at the bottom of the steam cylinder, the pipe communicating with the small cylinder is closed. When the piston is ascending, the steam passes though the pipe into the small cylinder, and raises the double piston above the orifice which leads to the steam cylinder, into which the lubricating matter is forced by the pressure of the atmosphere. When the piston is at the top of the steam cylinder, and a vacuum below, the double piston in the small cylinder descends by atmospheric pressure, and again opens the orifice leading to the steam cylinder, into which the lubricating matter enters as before. *Patent abandoned.*

273. J. Hill. *Improvements in the construction of portable chairs and other articles for sitting or reclining on road, Bath, invalid, wheel, and children's carriages, ambulances, or vehicles for carrying sick or wounded persons.* Dated Feb. 1, 1862.

The patentee claims a framework connected together by bolts or joints, such framework, when extended, being held in one given position by knuckle joints, and by the rods or pistons acting as a lever upon and regulating the opening and shutting of the same, and by means of the pressing down the lifting seat upon the spring catch, or other contrivance, rendering the joints and other parts rigid when in use. *Patent completed.*

274. J. Deprez. *Improvements in machinery or apparatus for extracting coal, ores, and other mineral substances from mines.* Dated Feb. 1, 1862.

This machine will be placed directly over the shaft, and the spindles or drums will act directly upon the barrels, and their alternate ascending and descending motion be given by a special combination, which consists in placing two separate axles, independent of each other and at suitable angles, the cranks and connecting rods intended to produce the reverse movement of the spindles or drums, and, consequently, the ascent and descent of the cables. *Patent abandoned.*

275. F. W. Daehne. *Improvements in furnaces used in the manufacture of zinc.* Dated Feb. 1, 1862.

This consists in causing atmospheric air to come in contact with the gases arising from the fire grate after they have left the grate and have traversed a portion of the furnace, whereby a complete ignition of the unconsumed products of combustion is effected. *Patent completed.*

276. T. Cook. *Improvements in machinery for punching, cutting, and pressing metals and other materials.* Dated Feb. 1, 1862.

Here the frame of the machine, so far as it is made with two jaws, the one carrying the hollow or bed-die and the other the punch or forcer, is similar to those heretofore employed, and the improvements consist in constructing and combining the parts for actuating the punch or forcing-die in the following manner:—The stem or holder of the punch moves up and down, and is properly guided in its movement. To the upper end of the stem or holder a sector, or segment of a circle, or an eccentric, is connected by a pivot or axis, on which the segment can move freely; above the segment there is a similar sector or segment of a circle, or of an eccentric, which moves on an axis or pivot covered by the framing. In order to actuate the punch or forcing-die, a screw is used to force a wedge between the two sectors, when the contiguous surfaces of the two sectors are concentric with their axes, or a parallel bar when the two contiguous surfaces of the sectors are eccentric to their axes. Provision is made for bringing back the punch or forcing-die after it has been caused to act. *Patent completed.*

277. J. Harris. *Improvements in mattresses, squabs, pillows, and other like articles of furniture.* Dated Feb. 1, 1862.

Here, in making a mattress or like article of furniture, two comparatively thin sections of a mattress, &c., in separate cases, are to be stuffed with hair, wool, &c., and between these two stuffed cases feathers are placed, and the two thin sections are sewn together at their edges, so as to produce a case to enclose the feathers, whether without a separate case. *Patent abandoned.*

278. T. Cook. *Improvements in machinery for folding envelopes.* Dated Feb. 1, 1862.

Here a sliding table is used carrying two die boxes, and the sliding table is arranged and worked so as to be moved to and fro upon a stationary table, in order to bring the two die boxes alternately under a plunger. The plunger descends twice into each die box; at the first descent it creases the envelope paper by pressing it into the die box. After the paper has been creased, the flaps are folded inwards by means of springs, levers, or instruments with which each die box is provided, and at the second descent of the plunger the folding of the flaps is completed. After the plunger has risen for the second time, the sliding table is moved a distance equal to that required to bring the other die box (covered by a piece of envelope paper) under the plunger. This movement of the sliding table also brings the die box, in which an envelope has just been completed, into a position beyond the stationary table, which enables it to discharge such envelope into a proper receiver. A fresh piece of envelope paper is then placed over this die box, which will be carried by the die box under the plunger when the sliding table is again moved. By these means envelope paper will be folded in the die boxes alternately when the boxes are alternately brought under the plunger. *Patent abandoned.*

279. W. Clark. *Improvements in machinery or apparatus for the manufacture of festooned edging or material.* (A communication.) Dated Feb. 1, 1862.

This relates to an apparatus for the manufacture of festooned edging or material. The material the patentee uses consists of ribbon or galloon cut according to the design to be produced; this is previously stiffened or sized, and in this state introduced into the machine; and in order to complete and cause it to retain the festooning or other form of the cutting, it is necessary to wind thread on to the galloon (or it may even be cardboard), and cross it. Lastly, the material is washed in order to remove the size or starch, and afterwards dried or pressed. The invention is not described apart from the drawings. *Patent completed.*

280. F. Riesbeck and W. Becker. *Improvements in locks or fastenings for bags, portmonnaies, and other like articles having metal frames.* Dated Feb. 1, 1862.

Here the patentees mount the principal part of the lock or fastening on the outside or main part of the frame (that to which the hand hold is attached), but another part thereof on the inner, or it may be termed the secondary part of the frame; on this part they place the thumb knob or piece to be acted on for the release of the catch or lock; consequently, if the bag or other article is held in the one hand, or even hung on the arm by the main or outside frame, the simple application of the other hand to the releasing knob will effect the release of the catch, and that part of the frame being simultaneously pulled away from the other, the bag or other article will be opened with facility. For this purpose it is only necessary to apply the hook or staple part of the catch on the inner frame, and actuate it by a spring, also fitted on that frame, so as to induce a tendency to keep it always in the locked position, from which it is driven by the pressure on the thumb knob or lever, as well understood in releasing spring catches. *Patent completed.*

281. M. A. F. Mennons. *Improved processes for the recovery of the oleic acid contained in the residual scouring waters of woollen and other textile materials or fabrics.* (A communication.) Dated Feb. 1, 1862.

The object of the first of these processes is to precipitate, under the form of an insoluble salt, the oleaginous matters contained in the water. By the second, the soap thus formed is decomposed. By the third, the oleic acid is separated from all the soluble salts formed in the preceding operations, as also from the excess (if any) of the acid used to effect the decomposition. By the fourth, the impure oleic acid is freed from the watery residues. By the fifth and last, this acid is separated from the insoluble salts and foreign matters which it may hold in suspension. One of the most important of these applications will be found in the utilization of the scourings of the woollen yarns and fabrics, and in the preparation of which large quantities of oil are consumed. *Patent completed.*

282. L. Hill. *Improvements in applying armour plating to war ships.* Dated Feb. 3, 1862.

The patentee claims the securing of armour plates upon the sides of war ships by fastening bars formed to overlap and protect the edges of the plates, and themselves fixed by screw bolts tapped into them from the inside, as described. *Patent completed.*

283. D. Joy. *Improvements in machinery for forging metals, also applicable to other purposes.* Dated Feb. 3, 1862.

This consists in actuating hammers (hitherto driven directly by tappets, cranks, cams, or eccentrics) by the intervention of a spring or elastic medium between such tappet, crank, cam, or eccentric, thus giving to the blow the character of elasticity; and to moderate the force of the blow the patentee takes up such elasticity by allowing the hammer, bar, or block to work in a cylinder, or itself to be a cylinder in which a piston is suspended; and he admits air freely to such cylinder to check it therein, thereby checking the blow due to the momentum of the hammer, bar, or block, driven as above described. 2. The invention has reference to steam hammers, and is supplemental to a patent dated Nov. 1, 1860 (No. 2668), and consists in leaving out the valve for the admission and exhaustion of steam, and in making the piston itself serve as a valve by allowing it to pass over and uncover a port or ports in the cylinder at proper intervals for the admission and exhaustion of steam; or he reverses the action, and makes the piston stationary and allows the cylinder to move over it. *Patent completed.*

284. C. W. Lancaster. *Improvements in strengthening cast iron ordnance.* Dated Feb. 3, 1862.

This invention consists in removing the rear end of the gun, including the whole of the cascable, before or after the gun has been strengthened with wrought metal in the form of a hoop or hoops, jacket or jackets, or both hoops and jackets, in forming a thread on the jacket or hoop, and in screwing thereon or therein a wrought iron or steel-breech end or cascable, so as to close the rear end of the gun. *Patent completed.*

285. C. Stevens. *An improved axletree.* (A communication.) Dated Feb. 3, 1862.

The chief feature of this improved axle is, that it is made in two equal parts, placed end to end in the same vertical plane, both movable and independent of each other. The other end of this double axle is of steel, spherical in form, and resting in a single concave bracket or support contained in a rectangular box. The wheels are wedged on the axle journals, and furnished with a central plate on either side, both wheels and plate being easily taken off. The axle has a shoulder at the outer part of the side bearing. The lower part of the central bracket and the outer parts of the side bearings are furnished with a tolerably large opening, by which they may be raised or lowered by a screw. The rectangular box of the bracket is formed of three pieces of sheet iron connected by tie pieces, or other suitable means, the upper plate being pierced with three apertures for the gearing. *Patent abandoned.*

286. J. J. King. *Improvements in the fastenings of bedsteads, which fastenings are also applicable to other portable framework.* Dated Feb. 3, 1862.

This consists in the application of a disc having snail grooves in the side, or other suitable snail pieces, which the inventor disposes in one part of the framework (in the horizontal rail by preference), while on the post or upright he fixes a dovetailed socket piece; this socket piece projects from the side of the post, and is received in a recess in the end of the rail. The disc snail piece he recesses in the end of the rail, and mounts it on a suitable axis, so as to present its periphery towards the end of the rail. The part of the periphery of smallest radius permits the insertion of the socket piece. The snail piece is rotated by a suitable key applied to its spindle. When fixing the parts together, the part of the periphery of smallest radius is turned to position, and the socket piece is fixed to the post inserted; the disc piece is then rotated, and the narrow part of the dovetailed socket enters the snail grooves on each side of the disc, while the broad part of the periphery is received in the wide part of the dovetail. The snail form of the grooves draws the parts slowly and forcibly together, and fixes and holds them firmly as required. *Patent abandoned.*

287. W. E. Newton. *Improvements in machinery for spinning.* (A communication.) Dated Feb. 3, 1862.

This relates to the motion of the delivering rollers during the operation of winding on in the mule jenny machines. The invention consists in giving to the delivering rollers during the winding on a differential or varying motion, which must be dependent on and governed by the circumference of the rollers and their speed of rotation during a given time; and also the distance travelled by the carriage during the same time. These motions must be arranged to decrease as the carriage approaches the delivering rollers, and the motion of the rollers may, if desired, be completely arrested before the carriage has arrived at the end of its course. *Patent completed.*

288. W. Clark. *Improvements in processes for preserving and colouring wood denominated xylochromic and xyloplastic processes.* (A communication.) Dated Feb. 3, 1862.

The details of this invention are too voluminous to be quoted here at sufficient length for an intelligible abstract. *Patent completed.*

289. T. M. Merkins. *The production of a projectile and explosive force to be used in instruments of war, for an electro-gas gun and electric-gas shell, for a method using the recoil of weapons, for the purpose of increasing the pressure of elastic fluids, for the production of a projectile force, for a method of rapidly loading weapons at the breech, and of a motive force to be used in an electric gas engine and other engines.* Dated Feb. 4, 1862.

This force is derived from the gases resulting from the decomposition of water at very high pressures by electricity. *Patent completed.*

290. G. Manwaring. *Improvements in flushing apparatus for closets, sewers, and other water services.* Dated Feb. 4, 1862.

This consists in self-acting mechanical appliances, whereby the closet is cleaned by supplying water through a cistern connected to and working with a small supply cock or inlet valve, to which the patentee applies an air vessel, by which the supply valve can be worked against any pressure with ease and soft action, the large outlet or discharge valve from which is closed while the inlet valve is opened, and *vice versâ.* *Patent completed.*

291. C. M. Roullier. *Improvements in the manufacture of straps, bands, chains, and other like articles.* Dated Feb. 4, 1862.

This consists in utilizing waste pieces of new or old leather, by employing them alone or combined with metal or other material for the manufacture of driving straps, bands, chains, and other like articles for transmitting motion or power, and in the mode of manufacturing the same. *Patent completed.*

292. P. Gardilanne. *Improvements in the manufacture of metallic wire fencing.* Dated Feb. 4, 1862.

Here the inventor employs a lath composed of a strip of hoop iron, pointed at top and cut out at bottom, to which is or are fixed one or more buttons, double or single. These buttons project on the flat part of the lath, and the wire lodges during its torsion between the lath and the head of the button. By the ordinary weaving machine, the torsion or twisting of the wire grasps or binds the lath on each side, whereas by the present invention the neck of the button is enveloped by one twist, either by a single or double chain. The lath being grasped on either side of the division, and held from top to bottom by the twist given at the button, it cannot possibly get out of place. As many holes as may be desired are pierced and cut out of the laths, which are then passed to a plate where the buttons are fitted. Thus prepared, the laths are delivered to the weaving machine. The weaving is effected by means of the single chain or warp formed of two wires, and of the double chain formed by four wires; the one and the other are twisted by machinery together with the lath and the button, and the fencing (which is then made) rolls during the weaving around a spindle. This fencing may be fixed on any description of posts. *Patent abandoned.*

293. J. L. Norton. *Improvements in beating, stretching, and drying fabrics, and in the apparatus employed therein, part of which apparatus is also applicable for thrashing linseed.* (Partly a communication.) Dated Feb. 4, 1862.

Here the operation of "beating" is effected by mechanism, instead of by hand, the fabric being caused to pass between two rows of sticks, which are fitted into metal sockets, and in connection with these sockets are short arms or projections, which, being acted on by tappets or shafts suitably arranged and driven, give the requisite motion to the sticks to cause them to strike the fabric. With this beating machine is combined a tentering, stretching, and drying machine. *Patent completed.*

294. R. A. Brooman. *Improvements in the manufacture of hard and soft soaps, and in the preparation of liquids for washing linen and other textile fabrics.* (A communication.) Dated Feb. 4, 1862.

The essential feature of this invention is the employment of alkaline silicates in the manufacture of toilet and household soaps, and in the washing of linen and other textile fabrics. *Patent abandoned.*

295. J. Greenwood. *Improvements in means or apparatus for preparing and combing wool and other fibres.* Dated Feb. 4, 1862.

In such machines it is now usual to apply a feeding comb just over the delivery or clearing points of the series of heckle points or teeth through which the fibre is conducted in its passage to the receiving or carrying comb. The inventor finds it desirable to place this feeding comb so that its position of rest may be somewhat backwards of that now adopted to admit of a dabbing brush or series of brushes, or series of plates or grates acting upon the fibre in the delivery or clearing combs, and he carries these brushes, or it may be a series of grates, upon levers, so that they may have motion given to them extra of that given to the ordinary grates or brushes acting with the heckle points in such machines. These levers are controlled to work so that the brush they carry will not come in contact with the dividing bar in its upward motion. He also applies a narrow fine comb to the part of the dabbing brush working into the receiving comb, and also one to work into the delivery or clearing comb. He also applies the teeth in the carrying comb at an angle, the teeth inclining forwards; and in place of this comb being controlled to move simply in a horizontal direction, he places the bearings of the rods by which it is supported in an inclined direction, so that its motion may be at an angle to the heckle point. He also applies between or about the heads of the front and back or other rows of comb teeth in the receiving or carrying combs, india rubber, or other suitable flexible material, to receive the edge of the plate carried by the dabber or nipper, or other detaining apparatus in such machines upon the fibre as fed into such carrying or receiving combs. *Patent completed.*

296. W. W. Williamson. *Improvements in apparatus for drying cloths and fabrics.* Dated Feb. 4, 1862.

This relates to a novel mode of constructing hot closets, in which clothes or other textile articles of domestic use are dried after being washed. The apparatus consists of a long box or chamber of suitable dimensions, and is constructed by preference of wrought iron, the framing being formed of T or angle iron, and the panels of two pieces of sheet iron, between which are secured a sheet of felt or other non-conducting substance. The panels thus made are secured to the wrought-iron framing by screws, bolts, rivets, or otherwise; and the several parts of the apparatus are secured together in such a manner by temporary fastenings as will admit of their being taken to pieces when required. The apparatus may be heated by a fire made in a separate fire-place but communicating with flues made in or adapted to the lower part of the closet, and so arranged that the heated gases will pass to and fro, or in a serpentine direction, so as to give off their heat to a stream of atmospheric air that is allowed to enter the apparatus from below, and pass over the heated surfaces of the flue pipes. *Patent abandoned.*

297. J. Webster. *Improvements in gas fittings.* Dated Feb. 4, 1862.

This invention refers: 1. To improvements in the knibs and burners. 2. To the slides of movable pendants or gaseliers. In making the knibs or burners the patentee cuts the aperture for the gas in such direction that the flame jets out downwards, and then rises upwards slightly in an unbroken form. In the argand burner he perforates the holes in a ring in the side of the burner, instead of upon the top; the effect of this arrangement is that the air acts upon the flame immediately as it issues from the burner, and more perfect combustion is insured. The improvements in the sliding parts of movable pendants or gaseliers, consist in the employment of a substitute for the balance weights and chains connected to the ordinary water slide, which substitute is thus formed upon the water cup. He screws a gland or stuffing box provided at the top with a screw or nut for tightening the parts round the fixed tube. He wraps loosely a strip of thin metal or metal gauze overlapping the joint, and he prefers for this purpose block tin in the form of thin sheets. Over this runner, and completely surrounding it, he places a short tube of vulcanised india rubber acting with equal pressure all round the metal runner; the rubber keeps the metal runner always in contact with the fixed gas tube. A loose collar is employed to work upon the top of the india rubber tube, compressing it, but without affecting the metal runner, and this loose collar is kept to its work by a screw and cap working into the stuffing box. *Patent completed.*

298. W. E. Newton. *Improvements in the manufacture of iron and steel.* (A communication.) Dated Feb. 4, 1862.

The patentee claims: 1. The conversion of iron into steel by subjecting it in the molten state to the combined action of potash, or other alkali, carbonate of lime, oxide of manganese, and charcoal, as set forth. 2. The purifying of the iron preparatory to such conversion into steel by the use in the smelting or other furnace, of the ores of zinc, in combination with jets of steam or water, substantially as described, when such purifying process forms part of a continuous process with the conversion, that is to say, when the iron is conveyed in a molten state from the purifying to the converting furnace. *Patent completed.*

299. D. Gallafent. *Certain improvements in the mode or modes of generating or producing elastic vapours to be used as a motive power.* Dated Feb. 5, 1862.

The object here is to obtain an elastic vapour or mixture of hot air and steam to be used as a motive power for high pressure engines, and the manner in which the patentee produces this compound of heated air and steam is by lighting a fire in a closed furnace surrounded by water, and afterwards forcing the heat and gaseous products of combustion from such furnace into the water space of the boiler, so that the water will be evaporated by the direct application of the heat of the fire, as well as by conduction. *Patent completed.*

300. W. E. Taylor. *Certain improvements in carding engines.* Dated Feb. 5, 1862.

This consists in driving the doffer from the "licker in" in order to stop the feed rollers when the "licker in" is stopped, thus preventing the injury to the card teeth resulting from the feed rollers continuing to supply the fibrous material when the "licker in" is stopped. One mode of performing the invention is as follows:—The "licker in" is driven as usual by a strap from the main cylinder, and the "licker in" by a strap gives motion to a pinion, by which the doffer is driven; the feed rollers are driven as usual by the doffer. *Patent completed.*

301. J. King. *Improvements in lubricators for lubricating the moving parts of machinery.* Dated Feb. 5, 1862.

This invention consists: 1. In applying a cover or guard to the ordinary oil cup employed on the brasses or bearings in which rotating shafts or axles of machines work. 2. In certain regulations to be placed in oil cups for regulating the flow of the oil. *Patent abandoned.*

302. E. F. Smith and T. Swinnerton. *Improvements in the manufacture of coke, and in kilns or ovens for the manufacture of coke.* Dated Feb. 5, 1862.

The patentees claim: 1. Passing a current of cold air by means of a stack through the coal being coked, the said current being made to pass from the exterior to the middle of the mass of coal being coked. 2. The improvement or improvements in kilns or ovens for the manufacture of coke, as described. *Patent completed.*

303. J. Browning. *Improvements in aneroid barometers.* Dated Feb. 5, 1862.

The first part of this invention consists in means of correcting the barometers for temperature, a requirement arising from the fact that, however carefully a vacuum is attempted to be established between the corrugated plates, yet some portion of air will remain between them; this air, expanding or contracting upon being influenced by extremes of heat or cold, renders compensation in the instrument, in order to render it perfect, or as nearly so as may be, necessary. These means of obtaining the compensation, or of correcting the barometer for temperature, consist in making the working parts, in some of them, of compound metals, or of metals of different degrees of expansibility. Another part of the invention consists in a new form and arrangement of the spring, connected to, and which takes the working from, the corrugated plates, to transmit it through other parts to the needle. The spring consists of a simple bent blade, formed in one piece, united by a screw, by which the spring is adjusted to the foundation plate or bed of the instrument; the other end of the spring plate terminates in an eye, by which it is connected to the working parts as hereafter explained. The invention also consists in the following arrangement of the working parts:—The eye in the end of the spring receives a stud, by which a slotted link is connected to the spring; in this link a stud, free to be moved and fixed at any desired point in the slot, is fitted; one end of this stud carries a roller, upon which the transmitting lever rests. From the transmitting lever the inventor carries a connecting blade to a short lever on the cradle, and he makes this lever so that it may be readily made shorter or longer, in order to obtain any adjustment required. He threads this short lever, and passes it through two plain eyes rising from, and forming part of, the cradle; then, by means of nuts screwed up against the eyes, he obtains the exact length required. Again, he forms the barrel, round which the chain passes for working the spindle of the needle, conical. *Patent abandoned.*

304. H. Ashworth. *Certain improvements in machinery or apparatus employed in spinning cotton and other fibrous substances.* Dated Feb. 5, 1862.

This invention consists, 1, in the employment of an endless band of felt or other material passing beneath the bobbins, having washers interposed, such endless band being distended between two vertical rollers, but depressed into a horizontal position (as beneath the bobbins) by other horizontal rollers. When the band is at a proper and required tension, the revolution of the bobbins causes or imparts to the band, by frictional contact, a slow but regular travelling motion, constituting a perfect "drag" upon the washers and bobbins, and with less wear to such "drag band" than hitherto, by reason of its continual movement. The invention consists, 2, in the formation and use of a projection upon the arm of the "flyer," arranged and shaped in such a manner as to catch up the slack yarns which sometimes occur between the flyer guide wires, and prevent it coming into contact with the revolving bobbin. *Patent completed.*

305. E. HARRISON. *A certain compound or certain compounds to be used as a substitute for gunpowder.* Dated Feb. 5, 1862.

This consists in an admixture of chlorate of potash, nitrate of potash, starch, yellow prussiate of potash, and charcoal, to form an explosive compound. *Patent abandoned.*

306. W. CAMPION and H. JOHNSON. *Improvements in machinery or apparatus for making the welts of hose or other articles made of looped or knitted fabrics, applicable also for other purposes.* Dated Feb. 5, 1862.

This consists in making the welts of hose or other articles made of looped or knitted fabrics, by the use of a hook and needle and cylinder, each of suitable construction, and operated upon by a cam and worm, and by a wheel. The needle used works inside the cylinder. The fabric of which the welt is intended to be made is placed on the cylinder, and upon the cylinder is secured a notch or pin, which comes in contact with a lever on each revolution, in order temporarily to stop the machine; the lever is again applied, and another revolution is performed. *Patent abandoned.*

307. J. LEO. *Improvements in traction engines.* Dated Feb. 5, 1862.

This consists in placing the axle on which the traction wheels of the engine are mounted about the centre of the length of the boiler, so that the said boiler may be balanced across the said axle, and one end of the boiler be raised or lowered by a lever when going down or up hill, in order to keep the boiler as near as may be level at such times. *Patent abandoned.*

308. J. B. PAYNE. *Improvements in the treatment or preparations of hemp, flax, and other analogous fibrous substances for spinning.* Dated Feb. 5, 1862.

This consists in submitting the crude fibres to the action of steam and friction at the same time. *Patent completed.*

309. A. V. NEWTON. *An improvement in firearms.* (A communication.) Dated Feb. 5, 1862.

Here the end of the barrel of the weapon is provided with a cutter, or a notched, toothed, or otherwise roughened edge, by applying the cartridge to which they may be readily cut or broken, and thus the necessity for biting cartridges is avoided. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated April 10, 1862.

1023. W. Nunn, 179 Saint George Street, St. George's-in-the-East. Improvements in the construction of lanterns for ships and signals.

Dated April 11, 1862.

1043. W. E. Gedge, 11 Wellington Street, Strand. An improved lamp for lighting mines. (A communication.)

Dated April 16, 1862.

1096. T. Edwards, Liverpool, gas engineer, and J. Harrison, Liverpool, ironmonger. Improvements in letter-receiving boxes and other like receptacles.

Dated April 21, 1862.

1155. S. P. Matthews, Wolverhampton. Improvements in vices.

Dated April 25, 1862.

1212. J. T. Davies, Liverpool, provision merchant. Improvements in circuit horse power. (A communication.)

Dated May 20, 1862.

1526. M. Vogl, Sambrook Court. Improved apparatus for protecting houses and other buildings from burglars.

Dated June 18, 1862.

1797. J. Wheater, Lee Mill, Bacup, Lancashire, mechanic, and J. Townend, Pippin Bank, Bacup, overlooker. Improvements in self-acting and other mules for spinning cotton or any other fibrous substances.

Dated July 1, 1862.

1915. E. F. Prentiss, Birkenhead, carriage manufacturer. Improvements in the construction of omnibuses and other four-wheeled vehicles.

Dated July 18, 1862.

2050. W. Gossage, Widnes, Lancashire, chemist. An improved method of and apparatus for decomposing chloride of sodium and chloride of potassium, for the production of compounds of soda and potassa.

Dated July 19, 1862.

2058. A. B. Brown, Castle Farm, Stockport, engineer. Improvements in steam engines and boilers.

Dated July 22, 1862.

2092. J. J. Haley, 7 King Street, Cheapside, merchant. An improved machine for wringing clothing and other woven fabrics. (Partly a communication.)

Dated July 23, 1862.

2096. A. Vignon, 20 Southampton Buildings, Chancery Lane, major in the corps of Engineers, France. Improvements in the means and apparatus for extinguishing fires either on land or water. (Partly a communication.)

Dated July 25, 1862.

2112. J. Anderson, Allan Bank, near Braco, Perth, starch manufacturer. Improvements in separating gluten from starch, and in preparing gluten for food.

2114. W. Clark, 53 Chancery Lane, engineer. An improved apparatus for decanting wine. (A communication.)

2118. E. Comfort, Richmond Terrace, Grosvenor Park, Camberwell. Improvements in watch protectors.

2120. E. Tysall, Riding House Street, Portland Place, electro plater. An improved manufacture of fork.

Dated July 26, 1862.

2122. A. V. Newton, 66 Chancery Lane, mechanical draughtsman. An improved mode of attaching armour plates to ships. (A communication.)

2124. J. H. Selwyn, Woodland Craig, Grassmere, captain in the Royal Navy. Improvements in apparatus employed in paying out and raising electric telegraph cables.

2126. R. Low and W. Duff, Dundee, brassfounders. Improvements in apparatus or means for producing an adjustable pressure on certain parts of machinery.

Dated July 28, 1862.

2128. H. Bollinger, Teesdale Iron Works, Stockton-on-Tees, engineer. Improvements in machines employed in ship building, part of which are also applicable to other purposes.

2136. A. Noble, Bristol, analytical chemist. Improvements in obtaining and treating compounds of alumina.

2138. J. Ellis, Witham, Kingston-upon-Hull, corn factor and dryer. Improvements in apparatus for washing corn and other grain.

2140. H. Hedgely, Great College Street, Camden Town. Improvements in lamps.

Dated July 29, 1862.

2148. E. T. Hughes, 123 Chancery Lane. An improved process of refining the slag from blast, puddling and other furnaces, and the employment of the refined material for mortar, stones, slabs, ornaments, and other similar articles. (A communication.)

2150. J. Norris, Great Russell Street, Bloomsbury. Improvements in the arrangement or construction of ovens.

Dated July 30, 1862.

2156. G. Nock, Brierley Hill, Stafford, steel and iron manufacturer. A new or improved safety or movable self-acting crossing for railways. (A communication.)

2158. W. E. Gedge, 11 Wellington Street, Strand. Improved means or apparatus for securing the safety of trains moving on railways. (A communication.)

2160. B. Bailey, Leicester, machinist. Improvements in means or apparatus for cutting chaff and other vegetable matters, which improvements are also applicable to cutting or mowing short or lawn grass.

2164. G. H. Birkbeck, 34 Southampton Buildings, engineer. Improvements in the means or processes employed for preserving timber from decay or destruction. (A communication.)

2166. T. Holt, file manufacturer, and F. L. Stott, machine maker, Rochdale. An improved composition or compositions for protecting polished surfaces of iron and steel against oxidation, and for renewing and improving the polish of such surfaces.

2168. J. W. Dixon, jun., Sheffield. Improvements in coffee urns.

Dated July 31, 1862.

2174. G. T. Bousfield, Loughborough Park, Brixton. Improvements in the manufacture of fluids suitable for burning in lamps and for other uses. (A communication.)

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

2161. H. White, Hampstead Road. Improvements in shirt collars. Dated July 30, 1862.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

879. T. Cole. Manufacture of figured ribbons.
883. E. B. Hart. Cutting cork. (A communication.)
891. W. Tyler. Composition for feeding animals.
894. W. B. Lord and H. Gilbart. Hame slip for suddenly releasing horses.
895. W. B. Lord and F. H. Gilbart. Firearms.
897. R. C. Ransome. Thrashing machinery.
901. J. M. Clements. Sewing machines.
912. F. Knudsen. Chronometers.
917. E. Hartley and J. Hinchcliffe. Rolling or straightening metal spindles, shafts, or rods of a cylindrical or tapered form.
920. J. Platt and W. Richardson. Applying motive power.
923. G. Holcroft. Blast furnaces.
927. W. Malam. Manufacture of gas.
930. B. Blackburn. Lubricating axles.
931. S. Hunter. Anchors.
932. T. Moore. Winding apparatus.
935. W. Leopard. Railway brake apparatus.
938. W. Helme. Fire-lighters.
939. R. Morton. Cooling liquids.
940. G. Bower and J. Qualter. Metallic pistons.
943. R. M. Toogood and J. Laybourne. Railway crossings.
944. W. Kemp and T. Cowley. Manufacture of silk pile velvet.
946. D. Wilson and E. A. Cowper. Pressing cotton, fibrous materials, and hay.
947. J. Lee. Traction engines and boilers.
948. A. Mann. Photographic apparatus.
949. W. A. Richards. Manufacture of bags.
951. J. F. Woodall. Ventilating carriages for common roads.
952. J. C. Kay and W. Hartley. Steam engines.
955. F. C. Bakewell. Letter-printing machines. (A communication.)
958. H. Fletcher. Valves.
961. R. A. Brooman. Case for holding balls and reels of cotton, silk, and other threads. (A communication.)
966. W. E. Newton. Manufacture of iron and steel. (A communication.)
976. L. Faconnet. Tiles.
979. B. Thompson. Steam engines.
983. A. Harris. Gun barrels.
984. E. Welch. Stoves, fire grates, ovens, and kitchen ranges.
985. G. Haseltine. Lamps for burning hydro-carbon oils. (A communication.)
988. J. Watremez. Indicating a deficiency of water in steam generators.
991. J. Brown. Protecting the bottoms and sides of ships.
999. J. Jaques. Instruments used in the game of Croquêt. (Partly communicated.)
1000. B. Sharpe. Harrows and rakes.
1008. S. Farron. Apparatus for regulating the supply of steam from the boiler to the cylinder or pipes of steam engines, which improvements are also applicable to gases or fluids.
1009. G. Hollinshed. Sandwich cases.
1011. W. Taylor. Preparing and spinning cotton.
1014. J. Langston. Manufacture of Portland cement.
1027. C. P. Coles. Masts for ships.
1029. L. Christoph, W. Hawksworth, and G. P. Harding. Drawing metals.
1037. W. Fox. Brooms and brushes.
1039. H. Holland. Manufacturing the stretcher joints of umbrellas and parasols.
1053. I. Whitesmith. Power looms.
1054. J. Bunnett. Revolving shutters.
1071. C. Harratt. Manufacture of masts, yards, and booms.
1111. J. Ashbury. Permanent way of railways.
1155. S. P. Matthews. Improvements in vices.
1168. S. S. Putman. Machines for forging horse shoe nails and other articles.
1181. J. Price. Spikes for railways and other purposes.
1498. R. Davison and T. Johnson. Washing and cleansing casks.
1525. E. Fewtrell. Manufacture of metal tubes.
1601. J. F. Harrison. Preserving the bottoms of ships.
1612. P. Boisset and B. Antoignini. Manufacture of boots and shoes.
1795. G. Haseltine. Roofs for railroad cars and hurricane decks of vessels. (A communication.)
1877. J. B. Coquatrix. Weaving carpets, tapestry, and similar fabrics.
2050. W. Gossage. Decomposing chloride of sodium and chloride of potassium for the production of compounds of soda and potassa.
2054. J. R. Abbott. Sliding chandeliers, gaseliers, and other pendent lamps.
2104. H. Rawson and F. Staples. Machinery for combing wool and other fibres.
2161. H. White. Shirt collars.
2174. G. T. Bousfield. Manufacture of fluids suitable for burning in lamps and for other uses. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed August 7, 1862.

358. J. Brinsmead.
361. J. J. M'Comb.
364. G. J. Aman.
365. F. Tolhausen.
367. J. Brickhill.
369. A. Hinshaw.
370. R. A. Brooman.
371. J. S. Joseph.
372. T. Spencer.
373. A. Samuelson.
376. J. S. Joseph.
379. W. Williams.
383. C. D. Abel.
390. E. E. Allen and J. Stewart.
392. E. Green and J. Newman.
399. T. D. M'Farlane.
408. C. Turner and J. Shaw.
417. J. Russell.
420. J. Hodgkinson and D. Greenhalgh.
423. E. T. Hughes.
424. T. Birdsall and J. Birdsall.
440. W. B. Adams.
451. E. M. Stoehr.
461. H. Ward.
474. J. Millington.
491. W. Clark.
499. J. Carnaby.
595. J. Sidebotham.
624. S. S. Bromhead.
745. M. A. F. Mennons.
904. W. M'I Cranston.
1650. L. Chaubart.
1712. G. Haseltine.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

1892. J. Sidebottom.
1836. J. Cannon.
1849. W. Muir.
1884. E. Stone.
1858. W. Bouch.
1878. C. Mather.

PATENTS ON WHICH THE SEVENTH YEAR'S STAMP DUTY HAS BEEN PAID.

1774. J. Macintosh.
1830. E. Topham.
1854. F. May.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, AUGUST 22, 1862.

PROPOSED NEW PATENT OFFICE BUILDINGS.

AT length a ray of hope's sunshine illumines the dark horizon of the Great Seal Patent Office, and there appears some chance of that ray developing itself into broad daylight. It is not necessary for us to expatiate upon the inconveniences, and annoyances which have for many years past beset the footsteps, and hampered the movements of would-be patentees. Those inconveniences and annoyances are, alas! themselves patent and notorious to very many of our readers, as well as to ourselves. The Patent Office of this country is one of its most important institutions, and yet the buildings in which the ever-growing business connected with it is carried on, are a standing disgrace and reproach to the scientific community. The rooms of the Great Seal Patent Office are at once dark, ill-adapted for their purpose, and far too small. The solitary advantage attending the place is, its central and accessible situation. This is marred, however, by its internal unfitness for its purpose, as too many witnesses are painfully capable of attesting. We are aware that much has been done by the present able and indefatigable Superintendent of specifications, Mr. B. Woodcroft, to lessen the evils which those have to undergo whose duty calls them to the Patent Office; but that gentleman cannot achieve impossibilities. There is a limit, even, to his performances. He cannot convert the sow's ear into the silken purse, although he has, perhaps, performed feats analogous to it in the dark recesses of the Chancery Lane sarcophagus. Out of disorder and confusion, he has produced order and regularity; and by what has been accomplished, under the greatest difficulty, he has shown what may be done in an open field, and with fair play.

We must return, however, to the hopeful gleam of light which gladdens our hearts, and which, we trust, will prove no mere "will-o'-the-wisp." The Commissioners of Patents have just communicated their report to the Lords' Commissioners of the Treasury, on the subject of building a new Patent Office, Library, and Museum, and they report most favourably on the undertaking. To the analysation of that report we shall now, therefore, address ourselves. The document sets forth in the first instance, *in extenso*, the report made on the same subject by the Commissioners of Patents in 1855. With the substance of that report, the readers of the MECHANICS' MAGAZINE of past days are no doubt familiar; but, as the circle of our subscribers has largely extended itself since the publication of the new series of this journal, it may not be irrelevant to note again its salient points. "In 1853," says this report, "these offices were sufficient in number, and "accommodation for the ordinary business of "the Patent Department. In the year 1855 "the Commissioners of Patents established a "free library within their office, containing "works of science in all languages, the pub-"lications made by the Commissioners, and "the works upon patented and other inven-"tions published in the British Colonies and "in foreign countries. This library has in-"creased, and continues to increase, partly by "purchase, but in a great measure by gifts, of "useful and valuable books. It was resorted "to at its first opening by inventors, engineers, "and mechanics, as well as by barristers, "solicitors, and agents; it has now become a "collection of great interest and importance, "and the number of readers has so much in-"creased that convenient standing-room cannot "be found in the two small rooms within the "office which only can be appropriated to the "library. It is the only library within the "United Kingdom in which the public have "access, not only to the records of the patents "and inventions of this country, but also to "official and other documents relating to in-"ventions in foreign countries, without pay-"ment of fees. A largely increased accom-"modation is urgently required." So said the Commissioners of 1855; and when it is remembered that the intervening time has witnessed a continual extension of the library, and a steady increase in the number of inventors and patentees availing themselves of it, the state of the Chancery Lane Patent Office may be imagined, even by those who have not sad reminiscences of visits paid to it. We say nothing of the Patent Museum, driven to take refuge in a small portion of the remarkable edifice reared by the not less remarkable Captain Fowke, at South Kensington, and facetiously known as "The Boilers."

It is needless to transcribe further the opinions of the Commissioners of the year 1855. Their report was, at least, unmistakable on the main point to which their attention was directed—that of increased accommodation and facilities for the researches of persons interested in inventions and patents.

The report of the Commissioners of 1862 recapitulates the fruitless negotiations which followed the presentation of their predecessors' ultimatum, and more especially those entered into for the possession of a portion of the gardens of Burlington House. As those negotiations were barren of results, it is not at all necessary for us to say more about them. Let the dead bury their dead: it is ours to treat of the living. After describing the arrangement of the varied contents of the Patent Museum at South Kensington, the Commissioners state that they "are also in possession "of a large number of valuable models, which "still remain in cases because room cannot be "found for them in the South Kensington" house of refuge. Indeed, they assert that "so "limited is the space there, they are obliged "to postpone the acceptance of many valuable "models, offered as gifts by manufacturers and "inventors. Several good models of machines "have also, for the same reason, been removed, "to afford room for machines of a higher "degree of interest." Thus it is that works which have cost their inventors much time, labour, and money, and which, under happier circumstances, might become excellent examples to young mechanists and others, are crowded out of sight; and might, for any practical use they are, be consigned to the care of the dealer in marine stores. It is truly remarked by the Commissioners of 1862, that, "in connection with the erection of the ne-"cessary buildings for the objects above speci-"fied, a most important consideration is the "spot to be selected for that purpose. The "readers in the library being of the class of "scientific persons, barristers, mechanical en-"gineers, chemists, inventors, skilled work-"men in the various factories, solicitors, and "patent agents, it is obvious that the readers "should be enabled to read the books and ex-"amine the machines and models at the same "time and in the same place." This position is so strong that we imagine no one will be bold enough to assail it. In fact, we have so often urged the desirability of uniting under the same roof, or at least of having in close proximity to each other, the whole of the adjuncts and accessories of the Patent Office, that it is needless to reiterate here that conviction.

So far, then, the Commissioners and ourselves are at one. We can scarcely say the same with regard to the site they propose for the new buildings. It is of the very last importance that that should be central, and therefore of facile access to the classes of persons whom the Commissioners very correctly designate as those most likely to require the aid of the Patent Office advantages. They state that in 1860, "we proposed to your "Lordships' Fife House and gardens in White-"hall as a convenient site for the Patent Office "buildings, and museum, and one that "would unite all the necessary requirements. "The question of the embankment of the "river stopped the way at that time, and "hence negotiations again hung fire. This dif-"ficulty is now removed . . . and it is conse-"quently open to Her Majesty's Government, if "it should think fit to do so, forthwith to ap-"propriate the site of Fife House for the erec-"tion of the Patent Office buildings."

This, then, is the culminating point in the last report, and it undoubtedly has the merit of propounding a practicable solution to the *vexata quæstio.* We have no desire to be unnecessarily fastidious, and would certainly prefer that the Patent Office buildings should be erected at Whitehall to things remaining as they are. Whitehall, nevertheless, is not the centre around which revolve those practical but lesser luminaries who would delight to add to their lustre, by borrowing some from the Patent Office, the Library, and the Museum.

With little difficulty we believe a site might have been found which would have fulfilled all the conditions that are essential to the full efficacy of the Patent Department of the State. It may be that some old buildings would have to be bought and removed to make way for the new institution, but the enormous funds available to the Commissioners would smoothe the way for the accomplishment of this end, and in all respects the public would be the gainers. If Fife House and grounds occupied the only site available for the proposed buildings, why then we should endorse cordially the views of the Commissioners; but as that is manifestly not so, we would ask them to cast a look in the direction of the existing Patent Office, and see whether it is not possible to obtain room in its neighbourhood for the new buildings.

The surplus revenue of the Patent Office applicable to building purposes amounts to 129,000*l.*; and as this amount is clearly derived from the pockets of inventors and patentees, it is plain that their convenience, as regards locality at least, should be a primary consideration. Still, as the Arabs say, "a "sparrow in the hand is worth a flock of "cranes in the air;" and if Fife House and gardens are to be had at once, we prefer having them, to entering into a seven years' discussion about some other site.

We are told that the Crown leases of Fife House, and the several buildings adjoining it, have lately expired, and that therefore the whole property is now at the disposal of Her Majesty's Commissioners of Woods and Forests in right of the Crown. This simplifies matters much, undoubtedly, and perhaps justifies the prayer for the appropriation of the site to the purpose named. The Commis-

sioners who append their names to the report, which is illustrated by a plan, are the Lord Chancellor, Sir John Romilly, Sir William Atherton, and Sir Roundell Palmer.

PETROLEUM.

Petroleum, which is now the subject of much discussion, has been for the past two years a new and profitable branch of Canadian enterprise. In less than six months New York has exported upwards of 2,961,317 gallons, about half that amount from Philadelphia, and between Baltimore and Boston somewhere about 228,000 gallons, which have been forwarded to almost all parts of the globe. England, however, has been the greatest consumer, having received 2,000,000 of gallons alone. A merchant in one of our large seaport towns states that this country absorbs about 42,000,000 gallons per annum; and he has even ventured to assert, that if the rocks and wells of Pennsylvania, Canada, and other districts, continue their exudation at the present rate of supply, the value of the trade in this ore may equal the cotton trade of America. Paraffin oil (which is the English name of refined petroleum) has had a great demand, no less than 500 tons having been sold weekly. Lubricating oils, wax for paraffin candles, naphtha, and benzole, from which the new and fashionable dyes are obtained, can be had from petroleum; and it is asserted that its uses may be extended to spirits of turpentine for painting.

The country from which this rock-oil is obtained embraces a vast extent of the American continent. Oil springs have, however, been sunk in but few localities as yet, and many of these have been abandoned in consequence of richer wells being discovered, which can be worked at a less expense. The pumping apparatus used consists of a small horizontal engine, which is connected by its pitman to a crank, and gives motion to a vibrating wooden beam, one end of which is attached to the vertical pump-rod in the well, which receives a reciprocating motion that operates the plumb plunger and lifts the oil. It is said that a coat of this oil has covered the surface of the river for seventy miles, which, when the sun shines upon it, reflects in beautiful green, crimson, and orange—their prismatic hues. Petroleum is sold in Pittsburg at the low rate of sixteen cents per gallon.

As to the origin of this oil, there are many conflicting opinions. It has been supposed to be of vegetable origin, produced by subterranean heat, but the more accepted opinion seems to be that it is derived from bituminous shales, situated below the coal formations. These bituminous shales have yielded enormous quantities of oils; but petroleum is not always found in this class of rock. Another opinion has been given that it has its origin in coal-beds—that a low heat in the coal-seams drives off hydrocarbon vapour, which is condensed in the pores of the rocks and the soil, and is washed by rains into subterranean recesses, which are situated at various depths in the rocky strata. There seems, however, every reason to conclude that these oils are both found in the bituminous shales as well as in the coal-beds. In the Mediterranean the island of Zante has been known to possess two springs of oil, which have been opened for 2,000 years; and it may fairly be conjectured that these oil springs of the new continent will afford an abundant supply of petroleum for many years likewise.

Two gentlemen of Philadelphia have made a series of experiments in order to form an estimate of the comparative illuminating power of petroleum, and they find that one gallon equals four of other burning fluid in giving a good light. They have also found that the best way to burn this oil is to have a clear straight cut of the wick; and that with a flame from a wick cut straight across, 2,576 gallons of oil gave a light equal to 1,000 cubic feet of gas, while with an arched flame 2,846 gallons of oil were required. It has been found, from experiments by the same gentlemen, that 35·53 lbs. of paraffin candles were required to produce a light equal to 1,000 cubic feet of gas; 41·16 lbs. of spermaceti and 47·18 of adamantine. It may be well worth notice here, that a great loss of light results from permitting beads of smoke to accumulate on the ends of candle-wicks.

Public attention has been repeatedly called to the explosive character of petroleum. We have, in the Mechanics' Magazine, given several accounts of the testing of the inflammable properties of this oil. The Insurance Companies made a stir about it before the Lord Mayor some few months ago. They stated that petroleum was in the highest degree combustible, and threw off an inflammable explosive vapour at ordinary temperature, and even at a very low temperature. They had made an experiment on a cold wet day, and found that it ignited on a light being held to it an inch from the surface. It floated, they said, and would not mix with water, and, being exceedingly volatile, it spread rapidly over the surface of water, burning fiercely when ignited. They complained that as there were alone on the Thames about 210,000 gallons of this oil, the property along its banks remained in daily jeopardy. The Lord Mayor had not the power to put down the storage of this dangerous material, but advised the deputation that awaited on him to petition the Legislature to regulate its introduction and use. Last week, at Liverpool, the town functionaries made a series of experiments, which have convinced them that the storage of this inflammable material in so large a town is a questionable procedure. We would commend to their notice the decision of New York respecting the matter, and urge them to take some steps to remedy any forthcoming evil. The Legislature of that city have prohibited the storage of this oil except in buildings suitable for the purpose, and in places where life and property are not likely to be endangered. The law in this country provides that all combustible materials—such as gunpowder, fireworks, naphtha, &c.—shall only be deposited in such quantities and in such places as shall render them of no danger to public life or property; and this law may be carried out equally with regard to petroleum. The experiments made at Liverpool leave no doubt in our minds that petroleum is a very dangerous oil, and, in case of an explosion, it would with great difficulty be got under. Professor Eaton, of New York, however, has stated that petroleum is not liable to spontaneous combustion, and several eminent chemists of America have agreed with him. He states that the light gas which evaporates from the crude material on exposure to air is vaporised naphtha; that no benzine proper is obtained from it; that the article called benzine, said to be distilled from it, is not true benzine; and that various oils obtained from petroleum have not been named by chemists.

We cannot dismiss our subject without referring to a laughable incident recently enacted at Liverpool, where, as our readers know, great excitement has for some time prevailed, in consequence of extensive storage of petroleum. A memorial had been presented from upwards of 1,000 inhabitants of Toxteth Park, complaining of the storage in that vicinity, as a nuisance; but a counter-memorial had been signed by a number of firms, stating that 30,000 barrels had been housed in Liverpool without accident. Just as the Town Councillors were assembling on the 6th of this month to consider these complaints, a man passed by and let fall, evidently for the benefit of the thousand memorialists, a jar containing this oil. The jar was, of course, shivered, and the man, having effected his purpose, ran away. The Councillors who had assembled inside rushed out of the hall to satisfy themselves as to the scent of petroleum, and were disgusted with the suffocating odour which was emitted from the jar. Evidently this incident had some importance in their decision, for we find that they declared that the oil was intolerable and dangerous to health, and, furthermore, was innocuous. Ultimately, however, they decided to refer the subject to the Health Committee.

IRONSTONE AND COAL-MINING IN A SANITARY POINT OF VIEW.

The report of the medical officer of the Privy Council, which examines the trades and occupations of Wolverhampton from a sanitary point of view, contains several important details worthy of attentive consideration. Everyone knows that the Wolverhampton district has many coal and ironstone mines. Sometimes these mines are found in juxtaposition to each other, and yet belonging to the same owner. As the miners do not work exclusively in either kind of mine, it would be impossible to ascertain the proportion in which the mining operations of the district contribute to produce the excessive mortality from pulmonary disease. The medical officer, however, assumes that, judging on the one hand from the prevalence of irritative pulmonary diseases among quarrymen and stonemasons, and on the other hand from the singularly low rate of mortality from these diseases in certain of the Durham colliery districts, he may consider that ironstone mining is more prejudicial to health than coal mining. The reasons for this state of things might, perhaps, be found in the defective ventilation of the mines, and the diffusion through the atmosphere of impalpable dust, and of the smoke and other products of the combustion of gunpowder used in blasting the mineral.

The report speaks in very disparaging terms of the condition of the mines of the town. It says:—"The greater part of the mines in "the Wolverhampton district are of small extent, employing but few hands, sometimes "not more than eight or ten. The mineral of "the district is nearly exhausted, the whole "country being, so to speak, riddled by mining "operations; and the surface of the earth for "several square miles presents the appearance "of a black waste of shale and refuse, interspersed with tramways, pools of water, and "the machinery necessary for working the "pits, varied here and there by the blast furnaces and other buildings connected with "iron works. The undermined state of the "country is shown by the great number of "ruined and misshapen houses caused by the "shrinking of their foundations. So frequent, "indeed, are the disturbances of the surface "from this cause, that roadways, canals, gas-"pipes, and drains are continually being "damaged by the displacement of the surrounding earth consequent upon the sinking "down of the roof of wrought-out mines."

The ventilation of the mines of Stafford-

shire, and, indeed, nearly the whole of the larger mines of the northern counties, is very deficient. On certain occasions, the atmosphere of the mine will be stagnant, or the direction of the currents so uncertain as to make the pits very dangerous to human life. A large furnace is constantly burning at the foot of that through which the outward current of air is intended to pass, which rarefies the air within the shaft, and "causes it to "ascend rapidly into the external atmosphere, "whilst a powerful current of air sets in to-"wards the furnace from the workings, in lieu "of which fresh air is drawn into the mine "by the 'down-cast shaft;'" but this has failed to convey fresh air to the innermost part of the mine, as the air will find its way by the most direct route from the point of entrance to that of exit. This defect, however, is obviated by a number of partitions, doors, and other means, which have the tendency of guiding the current of air in the direction that may be required, and so arranging it that one part of the current may pass up one, and another part up a different, roadway. By this means, though it is in a very tortuous manner, pure air is conveyed into every part of the mine, even up to the faces of the men, in order that the gases disengaged from the strata may be swept away. To this excellent arrangement may be attributed in no small measure the lack of those diseases which are engendered by imperfect ventilation; and the medical officer himself states that pulmonary complaints and premature death are often the issues of a want of proper attention to this consideration. The mines of Wolverhampton are known to be ill-ventilated, and the reason may be found in the fact that, the minerals being nearly exhausted, this complicated mode of ventilation is impossible, because of the expense it would necessarily entail. The coal and ironstone mines of the neighbourhood of Wolverhampton are furnished with what is known as the "down-cast" and "up-cast" shafts, but they lack the furnace to which reference has been made, which, if employed, would rarefy the air. Consequently, notwithstanding other precautions, the ventilating current is uncertain and fickle. When a stagnation of the air occurs, the remedy is resorted to of suspending from the top of the "up-cast" shaft an iron basket of fire, which, in small mines, has, though to a less extent, the same beneficial tendencies as the more expensive and decidedly superior mode of ventilation in the Northern mines. Though the imperfect ventilation of the mines of this town is a fact that has been attested by Her Majesty's inspector of mines for North Staffordshire, and confirmed by various gentlemen of position in Wolverhampton, the mines of that town are not all subject to the same censure. We learn from the report before us, that in some of the mines the up-cast shaft is arched over at the top, and by its side, on the surface of the earth, is a closed furnace, dependent on the shaft for its supply of air. This has the effect of causing a considerable draught of air through the shaft, which, in passing through the furnace, finds its way out by the chimney, and must be replaced in the mine, by the admission of fresh air through the "down-cast" shaft. We are told that "in other cases, a tube, fitted at the "upper end with a movable funnel-shaped "cowl that shifts with the wind, is conveyed "from some distance above the surface of the "earth to the bottom of the shaft, and even "sometimes into the recesses of the mine, by "means of a tube joined at right angles to the "descending tube." Of all these plans, however, the best is considered to be an indifferent substitute for the one we have described, which is more costly, but a much more effectual system of ventilation.

Having shown the want of sufficient ventilation in the small mines of this district, the report proceeds to consider the effects of this state of things upon the miners. As we stated at the commencement, the miners do not work exclusively in either the ironstone or coal mines—sometimes alternately working in both; consequently, the medical officer cannot possibly ascertain the exact proportion of the deaths from consumptive diseases. However, there is, unfortunately, sufficient evidence of the injurious influence on their health from their occupations. There is a great prevalence of chronic bronchial affections and of phthisis among the miners, which the resident medical practitioners have attributed in a great measure to the miners' employment, as well as in part the cold bleak climate of the district. Asthma is also a common disease, and is principally caused by the miners working in damp clothes. Out of twenty-five persons who were examined by Her Majesty's Inspectors, nearly all of whom belonged to different mines, only four stated the occupation of mining to be a healthy one; and two of these qualified their statement by saying, that men who work in mines that contain much damp are liable to suffer from dyspnœa, cough, and expectoration. The remaining twenty-one agreed in the opinion that both coal and ironstone miners are more liable to suffer from asthmatical disease than other people. The report concludes by stating that it was found more difficult to meet with broken-down miners for the purpose of examination in the Wolverhampton district than in the mining districts visited and reported on last year; but such as were examined were found to be suffering from the same class of ailments as the Cornish and lead miners. Chronic bronchitis and its results are the complaints to which the Wolverhampton miners are subject, but the disease appears to be slower in its progress than is the case among tin, copper, and lead miners. A greater proportion of the Wolverhampton miners likewise escape the disease, or suffer from it in a mitigated form, and there is a greater tendency to recovery after ceasing to work in the mines. Several old miners were seen, who, having ceased to work under-ground in consequence of miners' asthma, had in a great measure recovered their health, and were able to follow some light occupation on the surface of the earth.

We conclude our notice by recommending this question, which is of essential importance to the health of a great number of able-bodied colliers, to the careful consideration of those who are the proprietors of mines in the district of Wolverhampton, and incidentally to those of other districts whose mines are deficient of proper ventilation.

THE INTERNATIONAL EXHIBITION.

THE PROCESSES COURT.

THE Processes Court has been for some time becoming more attractive day by day. It is likely, that had the Commissioners foreseen that it would be so popular, they would have given it more space in a better position. It is hemmed in on one side by the Hardware Court, and on the other it is almost thrust under the stairs of the Picture Gallery. Of the many persons who pass through it, most of them stumble upon it by accident, and there are many thousands who leave the Exhibition without having seen it at all. The visitors, both gentle and simple, are much interested in the handicraft operations which are to be seen in this Court. Lithographic and steel-plate printing, velvet weaving and medal cutting, tobacco-pipe and pencil making, have inquisitive spectators watching them all day long. The sewing machines, too, are numerous in this quarter, fourteen being exhibited, and eight in constant operation. It is likely that, when they are understood better, and become cheaper, the sewing machines will be the implements of labour in all industrial occupations where the needle is the principal tool: hence the curiosity with which they are inspected by many who are amazed to see fabrics put together with a rapidity and a neatness which our mothers, not to speak of grandmothers and more remote maternities, would never have dreamt of. Most of them have an ingenious contrivance by which they lay down a hem as neatly as ever the mistress of a dame's school could have laid it down for her young disciples, and will sew it as firmly as ever dame could have desired, and far more neatly.

The machines exhibited in the Processes Court are all of English manufacture. Some of them avow their American origin, while others claim English improvements, which merit the name of inventions. It would be needless to describe them all in detail, but we give the names of the various exhibitors:—

BRADBURY & Co., Oldham.
W. CARVER, Manchester.
FERRABEE, High Holborn.
GUINNESS & Co., Cheapside.
M'KENZIE & Co., Glasgow.
M'KERNAN, Cheapside.
NEWTON, WILSON, & Co., High Holborn.
PEARSON & Co., Leeds.
SALISBURY, Coventry.
SERVICE, Mitcham.
SIMPSON & Co., Cheapside.
SMITH & Co., London Wall.
THOMAS & Co., Newgate Street.
WHIGHT & MANN, Holborn.

The machines of Mr. Thomas are the oldest and best known in this country, at least in London. They are manufactured in various sizes, adapted for different kinds of work, and are extensively used by army contractors, by the Military Clothing Establishment at Pimlico, and in the manufacture of shirts, collars, stays, sacks, harness, &c. It was generally believed that, as Mr. Thomas had purchased the machine and patent of Howe in 1846, the machines he has vended since were those of Howe's invention; and we must confess that we shared in that belief. Mr. Thomas claims, however, to have invented and constructed an entirely new machine, differing essentially from the one purchased by him from Howe. There is certainly a difference in the means by which the tension on the needle thread is regulated, and an ingenious contrivance under the needle-arm apportions the quantity of thread drawn from the reel to the thickness of the material to be sewn. But the most obvious difference is in the feed motion. Howe's machine has a wheel-feed underneath. The machine of Mr. Thomas has what is known as the upper feed. This upper-feed motion has been long since abandoned by all American machinists, as being in no way comparable to the four-motion feed, the invention of Mr. A. B. Wilson. Mr. Thomas's machines, however, from their solid construction, are well adapted for heavy work and extensive manufacturing, for which purposes they are largely employed.

Mr. Carver has two machines here almost identical in their construction with Mr.

Thomas's, and they have certainly been the most productive of any machines in the Exhibition. They are worked by two young women, one of them a mere child, in fact, and they have turned out nearly 2,000 pairs of trousers, or somewhere about twenty pairs a-day, since the opening of the Exhibition.

Mr. Salisbury exhibits a machine which is so far a novelty in that it carries a bobbin underneath, instead of a shuttle. The bobbin is made to perform half a revolution, and then return, when the slack thread it casts off is caught up by a hook and twisted round the thread carried down by the needle, by which means a knot is tied at every stitch. The machine is called a "knot-stitch machine," and the security of the stitch is indisputable. Should one stitch be cut, the one lying next it is protected by its knot, and can only be undone by cutting it also. For all kinds of heavy work the machine has a peculiar excellence, and deserves more notice than it has yet received.

Messrs. Newton & Wilson, of High Holborn, make an excellent display of work performed by the sewing machine, in which it were difficult to say whether most credit is due to the machine or the operator. Their machine is a chain-stitch, known in America as the Grover and Baker machine, in which the vertical needle is employed, but, instead of a shuttle, it is accompanied by a second needle of a circular form, with a backward and forward rotatory motion on a horizontal plane, and carrying, through its outer eye, the thread coming from a bobbin, which may be of any size whatever, like the one which feeds the vertical needle. The relative motion of those two needles is so complicated that it would be impossible to give a proper idea of it without diagrams. There results from it a double chain-stitch, in which the successive loops of the upper thread are traversed and embraced by those which are made by the lower thread, so as to unite solidly two pieces of cloth. The stitch of this machine it is not easy to pull out; and, although it forms a seam a little raised, through the interlacement of the loops, it presents very ingenious combinations. It works with great rapidity, and is almost noiseless in its operation—prime qualities in a machine intended for family use. For several years Grover & Baker have been turning out their machines at the rate of fifty per week. They obtained a second-class medal at the Paris Exhibition, and were used by the French Government at their establishment for the manufacture of military equipments.

Guinness & Co., of Cheapside, exhibit the most recently-patented machine, remarkable for its neatness and simplicity of construction, and which might be fitly described as a machine without any machinery. It is a shuttle machine, worked without cams, by an equal crank motion, one shaft working three cranks—one for the shuttle, one for the needle, and the other for the feed. By this equable motion, the needle does not rest while the shuttle passes through the loop, as in other machines; it may therefore be worked either backward or forward at pleasure, securing the thread at the end of each seam without the help of hand-work. The needle-arm works on perpendicular rods, using a straight needle, which, requiring no oil, promotes the cleanliness of the operation, and avoids the liability to soil the work, which has been an objection to some other machines. The machines now exhibited by this firm are specially adapted for family use; but they are constructing others on the same principle for manufacturing purposes, which we have no doubt will enter powerfully into competition with those now in use. We have already hinted at cheapness: let us here remark, that simplifying the mechanical construction of the sewing machine will but accomplish half its purpose, unless it is thereby greatly reduced in price. It will be in vain to look for it as an indispensable adjunct to the household laboratory till it is brought within reach of the bulk of the community.

Guinness's machine is the only one in the Processes Court which has been recognised by the Jurors, and to this they have awarded "Honourable Mention." It is with some show of reason that the Exhibitors here complain of the Jurors having unfairly judged the machines of English manufacture. All the American, and most of the other foreign machines, have received an award, and it is singular if there was not sufficient merit in those of the United Kingdom to entitle any of them to the distinction of a medal.

R. E. Simpson & Co., of Cheapside and Glasgow, have got an enviable position in this Court, and make an excellent display of their machines. We have here also a shuttle machine, the chief difference in which, from those we have already described, being an underfeed motion on each side of the needle, by which, it is said, the material to be sewn can be turned or curved with greater facility. The appliances by which the machine is worked are cased in, preserved from dirt and injury, and giving to the whole a very neat and compact appearance. They are finished, too, with more care than the generality of the English-made machines, and evince a superiority in this respect which can be seen at a glance, and which is highly creditable to the Glasgow artificer.

Messrs. Whight & Mann, of Holborn, show a small machine, which makes a chain-stitch like the Grover & Baker, but which the exhibitor terms a double loop. Here we have a different feed motion from any of the others; that is, a needle feed, in which the needle, attached to the disc of a small wheel, is made to describe part of a curve, and in penetrating the cloth moves it forward at every stitch. One can see that this kind of feed can only do with very light work, such as light and nimble fingers can effect. But every machine that we have seen is only adapted to its own special work. The machine that shall do every kind of work, and do it well, has yet to be invented.

THE TRUE PRINCIPLES OF AIR NAVIGATION EXPLAINED.

TO THE EDITOR OF "THE MECHANICS' MAGAZINE."

Sir—The achievements of modern science prove the impossibility of man setting bounds to human ingenuity, and the achievements of flying animals prove the practicability of a science frequently testing man's ingenuity. But how unsatisfactory the result terminates, if, in the hope of gleaning any useful information practically available for realising the navigation of the air, we review any of the numerous schemes and suggestions which have been proposed, even by men of very creditable reputation! This result undoubtedly arises from the fact that so many have been influenced in their endeavours to accomplish it by the buoyancy of a substance of *much less density* than the air. Others have been equally unsuccessful through the difficulty of obtaining an adequate motive power without excess of weight; the consequence of which is that, because they have all signally failed, we feel warranted in concluding that its achievement by man is utterly impracticable: so that if anyone proposes an additional scheme we are prone to condemn him at once as "only plodding over well-trodden ground." But, notwithstanding that this subject has hitherto baffled every effort, it may yet be well to pause before condemning it as hopelessly impossible, and endeavour to inform ourselves correctly of the principles upon which the success of flight depends, and the manner by which they are developed in the actions of all flying animals, all of whom are formed of materials of *much greater density* than the air; and their successful example, though natural, clearly demonstrates its practicability by artificial means. Consequently, in an invention of this nature, it becomes preeminently necessary to obtain a correct knowledge of the principles adapted by the Creator for sustaining all flying animals; for by the adoption of those principles only which are most true to nature can we hope to succeed practically in navigating the air. The difficulty of obtaining this knowledge is, however, somewhat considerable, because it demands the closest observance of the actions of flying animals during their flights, and the rapidity with which such actions are performed often eludes the keenest watchfulness: also it is often extremely difficult to interpret correctly the operation of even the simplest law of nature. By carefully examining the formation of their wings we may derive great assistance, although the mode of operation has been greatly misconstrued; for all writers assert that the action of the downward stroke alone produces the upward and onward effect. By one it is thus stated:—

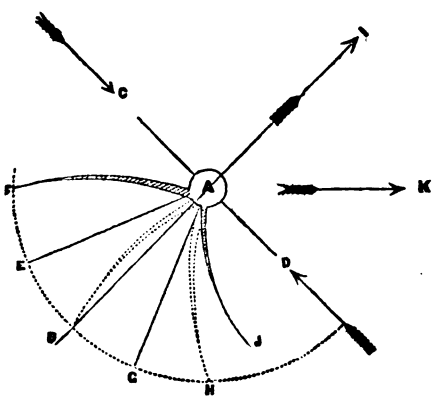
> The stroke of a bird's wing is always perpendicular, and this *one action serves both to sustain and to propel*. This is a result as well of the structure of the whole wing as of the structure of each feather. The feathers are all so placed with reference to each other that in the upward stroke they tend to separate and allow the air to pass between them; while in the downward stroke they are pressed against each other so as to present to the air one impervious expanse, and thus to secure the greatest possible amount of atmospheric resistance. But the most beautiful part of the structure is that which converts the stroke for sustaining into a stroke for propelling also. The quills are so set that the elastic ends constitute the terminal and posterior margins of the wing. The anterior margin of the wing is rigid—being that containing the bone. The consequence of this arrangement is, that the air compressed by the downward stroke escapes backwards, bending upwards in its passage the fine elastic tips; and thus exerting an upward and onward re-action on the whole body of the bird.

The fallacy of this argument is in asserting that "one action serves both to sustain and to propel," and also "that the air compressed by the downward stroke escapes backwards, bending *upwards* in its passage the fine elastic tips." Had such a result been intended it evidently would not have been guarded against by the Creator, who, in order that the feathers may resist the more firmly every tendency to bend them upwards, has imparted to them a downward curvature of such tenacity, that even the entire weight of the bird is insufficient to bend them outwards during life; and, further, it possesses the power of increasing and maintaining the curvature of the feathers at will, because all the atmospheric resistance derived from the downward stroke is fully required, or nearly so, to support the body in opposition to the gravitating influence of the earth.* The downward stroke is therefore solely designed for elevating and sustaining the bird, the curvature imparted to the feathers and structure of wing enabling it for that purpose to retain to the utmost its hold of the air throughout the entire stroke, and thus prevent it from escaping backwards. Moreover, it is evident that during the time in which the momentum derived from the downward stroke is being neutralised by gravity, the animal performs the upward stroke, and throughout this action the air offers a resistance against which the elastic edges, unable to retain their former expanse, instantly bend (down-

* The cruel practice of clipping birds' wings is a proof that the wounds so inflicted are such as to render them incapable of flight, because they cannot sufficiently curve them afterwards; if they could, a slightly increased velocity of a reduced surface would produce the same result from the same power, and which could be applied by the bird, because its power would not be reduced by shortening the feathers if no pain was endured.

wards), and, by this simple provision, such resistance is thrown or impinges on the anterior margin of the wing below its centre, and produces the onward propelling effect. It is probable, however, that when the body has an oblique direction to the line of motion (as when rising or settling, or as the body of some insects have during their actions), the atmospheric resistance is caused by the elastic structure of, or by slightly changing at the end of each stroke the position of, the wing, to impinge alternately above and below the centre of its arm, so that the reciprocating actions in this position produce most equally an upward and onward effect throughout each (not one) stroke. Whereas, when the direction of the body is horizontal to the line of motion, each stroke in that position participates in the progressive motion most unequally—the upward stroke contributing chiefly or entirely to propel the body, and the downward stroke contributing chiefly or entirely to sustain the body.

The annexed diagram illustrates the reciprocating action of the wings or propellers:—



Let A represent the arm or anterior margin of the wing, B A the plane or surface of the wing (dotted), C D and D C the direction of the reciprocating actions or strokes. Now if the position of the propeller is changed from B to E, or, being elastic, the resistance offered to the downward stroke will give the surface the position as at F, and be thrown or impinge on the arm of the propeller at its conjunction at A, and remain on the same side of, and above the, centre B I, throughout the entire stroke from C to D; exerting an upward and onward reaction on the arm. If, when the downward stroke is performed, the propeller take the position at G, and, being elastic, the resistance offered to the upward stroke (against which the elastic edge, unable to retain its full expanse as at H) will cause the curvature to take the position as at J, and the resistance in this action will impinge and remain below the centre of the arm B I, and produce an onward and upward motion throughout the stroke from D to C. From these reciprocating actions it is evident that, so long as the motive power impelling the wings, and the elastic force or density of the air resisting the surface of those wings, exceeds the weight or density of the body to be raised—or, which is the same thing, the force of gravity—the line of motion will be in the direction from B to I; and when the atmospheric resistance on the surface of the propellers and the gravitating influence of the earth on the body are equal, the line of motion will be in the direction from A to K, or horizontal; and by increasing or decreasing the motive power a change of altitude will be attained. (Of course with birds, and probably insects, this change is effected by their tail, and often when the action of their wings is altogether suspended.)

As this reciprocating action is performed between one or more pairs of propellers, the direction of the current of air thus set in motion by each propeller is met, resisted, counterbalanced, overcome, and reversed, by the action of the opposite propeller. This sudden and continually changing of motion of the current of air by the propellers causes additional compression of the air in the direction of that motion, and thereby developes that remarkable property of air, its elasticity, i.e. the property of resisting compression, which makes the incredible difference between the resistance experienced by surfaces when set in motion circularly, or projected longitudinally, or when acted upon by the air in motion; and the resistance, or rather the impact of the air to surfaces when set in motion, as in the action of any flying animal.

The following is one result of several experiments with two pigeons, conducted expressly for ascertaining the strength and weight of the birds and the surface of their wings, and for obtaining as a basis correct and reliable information respecting the resistance offered by the air to a given surface propelled in the manner and at a velocity common to birds. For although the velocity with which they work their wings is rapid, it does not, during the most violent exertion, exceed three actions per second, being limited to such as can be repeated and maintained with perfect ease to the animal; and although in some instances the eye can scarcely distinguish the strokes, in others they can be distinctly counted, as in the flight of rooks, whose slow movements do not exceed or even reach at times one action (consisting of the upward and downward strokes) per second. They also will often suspend all action of wing entirely for upwards of eight seconds at a time, and during such suspension will sail a considerable distance, and even then also rise higher from the momentum obtained.

Experiment with Male Bird.

The weight of this bird was 7,270 grains troy = 1·04 lbs. av.
The weight of greatest load, 5,303 grains troy = 0·76 lbs. av.

The total weight lifted 12,573 „ „ 1·8 lbs. av.

The surface of wings equal to 83½ square inches. At 6 inches from the centre of back, being midway between back and tip of wing, the wing was 4½ inches wide; the average length must therefore be taken at 9¼ inches (the greatest length being 12 inches), which multiplied by the width gives 41¾ square inches as the surface of each wing.

Experiment with Female Bird.

The weight of this bird was 5,356 grains = 0·77 lbs. av.
The weight of greatest load, 5,303 grains = 0·76 lbs. av.

The total weight lifted 10,659 „ 1·53 lbs. av.

The surface of wings equal to 70 square inches. At 5¼ inches from centre of back, being midway between back and tip of wing, the width was 4⅜ inches; the average length must therefore be taken at 8 inches, which gives 35 square inches as the surface of each wing.

Experiment with Insect—a Blue-bottle Fly.

The weight of this insect was 1¼ grains, with greatest load 2¼ grains; the surface of wings 0·125 square inch.

Having therefore the weights of these bodies and the surface measure of the propellers by which such weights were raised and supported in air, we have now to find the *true* velocity required of such surfaces to raise their respective weights.

Fig. 1.

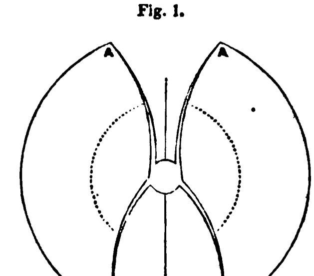


Fig. 2.

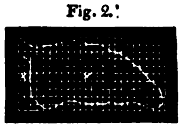

In the above diagram, fig. 1 represents the size of the natural wings (male bird's) in their raised and depressed positions, and fig. 2 an outline of the surface expanded as when in action, and the mode of measurement adopted. They are reduced to one-sixteenth of the original.

Birds when flying seldom elevate or depress their wings so much as to bring them in contact either above or below the body: in most instances they are not passed through an angle greater than 90° on each side. The above diagram, however, represents the stroke of each wing, commencing at A A and terminating at B B, as being propelled through an angle equal to 135°, and the dotted circle represents the distance through which the whole surface of the wings are propelled, the diameter of which must be equal to the length of one wing. The male bird's wings being each 9¼ in. long, gives that distance as the diameter of such circle, the circumference of which is equal to 29·06 in. If the wings are propelled through 270° of this circle, we have 21·8 in. as the distance through which a surface equal to 41¾ square in. is propelled at each stroke (or twice that surface through half the distance) to raise a natural weight of 1·04 lbs., and when loaded 1·8 lbs. What, then, is the required velocity of such propellers? A surface equal to 41¾ square in., if propelled at a velocity equal to 52·5 feet per second, or 35·8 miles per hour, will, according to the rule given by Playfair, meet a resistance equal to 1·8 lbs.; and when propelled at a velocity equal to 45·5 feet per second, or 31 miles per hour, will meet a resistance equal to 1·04 lbs. In the second experiment (female bird) the surface employed to raise its natural weight of 0·77 lbs. is equal to 35 square in., which, propelled through an angle equal to 270° of a circle 8 in. in diameter, gives 18·8 in. as the distance through which such surface is propelled at each stroke; and the velocity required according to the above rule ($S \times V^2 \times \cdot 0023$) is 37·5 feet per second, or 22 miles an hour, to obtain a resistance equal to 0·77 lb.; and 53 feet per second, or 36 miles an hour, to enable it to lift 1·53 lbs.

From this we may readily ascertain the number of strokes, required by the rules generally established, which each bird must perform to raise its natural weight and load:—

Surface of wing	Space propelled through at each stroke	Velocity (Playfair's rule)	Number of actions per second required of bird	To raise its natural weight, also weight and load
Square in.	In. ft.	Feet per second / miles per hour		lbs. avoirdupois
Male bird 41·75	21.8 = 1·82	45·5 or 31 52·5 „ 35·8	25 29	1·04 1·8
Female bird 35	18·8 = 1·57	37·5 „ 22 53 „ 36	24 34	0·77 1·53
Insect 0·125	0·75	3·3 „ 2·25	53	1·25 grains

This table shows that the male bird, in order to raise its natural weight of 1·04 lbs., must make 25 actions, or 50 strokes of its wings per second, and propel a surface equal to 41¾ square inches through a distance of 45·5 feet! and the female bird must make 24 actions, or 48 strokes, of its wings per second in order to raise its natural weight of 0·77 lbs., propelling a surface of 35 square inches through a distance of 37·5 ft. in one second!

That the application of any such rules as the above to the subject under consideration is monstrously erroneous, must be apparent to anyone who will take the trouble to notice for a few minutes the actions of these animals during their flight, as he may not only distinctly see the movements of their wings, which he could not do if

they repeated these actions only four times per second, but even perceive them suspend all action of wing entirely for several seconds at a time, and during such suspension to rise higher or change their course at will.

I will conclude what I have to say on this subject in another letter.—Yours, &c.,

W. Quartermain.

TONNAR'S IMPROVEMENTS IN DRYING AND CLEANSING MALT, &c.

Fig. 1.

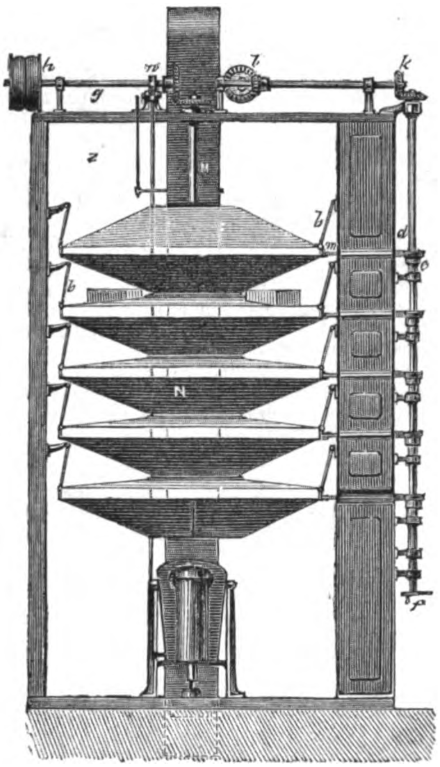

Fig. 2.

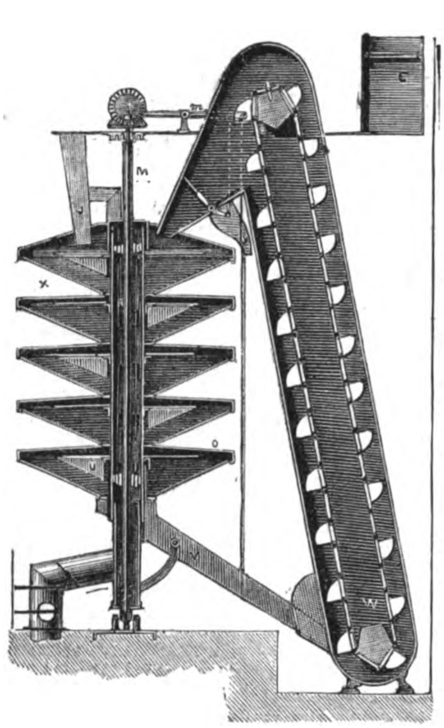


Monsieur A. Tonnar, of Eupen (Rhenish Prussia), has just obtained a patent for "Improvements in the method of and apparatus for drying and cleansing malt, as well as any other species of grain and seed intended for brewing, distilling, and agricultural purposes."

This invention has for its object the drying and cleansing of malt and any other grain and seed in a more perfect manner than has hitherto been effected by kilns, frames, or any of the ordinary modes.

The green malt or other matter to be dried and cleaned when taken from the airing granary, is poured first into a receiver having three compartments with openings at the side, and a bottom formed of metallic network or sheet iron pierced with holes, under which the heat is supplied. The receiver is connected to a shaft or axis, and is turned until one of its side openings corresponds with a funnel, by which the malt, heated and partially prepared in the receiver, is poured upon the first of a series of discs fixed to a tube connected to a shaft, which is made to revolve. In some cases the receiver is dispensed with, and the malt from the airing granary is passed at once through the funnel to the discs, which revolve in baskets, the lower parts of which are shaped like a funnel, and composed of metallic network or perforated iron plate. Each cover of the basket is provided with two openings, having over them metallic network. The discs have small wings, which jerk the malt, grain, or seeds, against partitions placed laterally in the baskets, and the damp air escapes through the network openings at the top.

There are two large ventilating wings for distributing the heated air on the descending malt and expelling the damp air. This operation is performed in each basket, after which the malt or other grain is conducted by a jolting spout to an elevator, by which the matter is conveyed again to the upper disc, and the operation repeated as often as required.

When the malt or other matter is sufficiently dry, the upper spout of the elevator is closed and a conductor opened, through which the malt passes from the machine.

The lower part of the baskets may be made of sheet iron, and the covers and sides made of metallic network. In this case the jolting spout is perforated, and also the bottom of the lower basket, for providing the means of sifting. These arrangements may be still further modified by making the cover, sides, and a portion only of the lower part of the basket, of metallic network or perforated sheet iron; in this case ledges or slabs are provided to prevent the waste from falling on the lower basket.

The jerking or projection of the malt by the centrifugal force against the partitions in the baskets, divides it from the radicles that are still damp, and the concussions and also the ventilation expel these radicles and all other impurities out of the machine through the meshes of the network.

This invention consists not merely in the apparatus, which is susceptible of modification, but in the peculiar system combining the employment of centrifugal force for putting the grain in motion, for dividing and separating from it the waste, for the distribution of the heat, for clearing away the damp air, and for the ventilation and sifting.

The manner in which the invention is to be performed will be understood by referring to the above engraving.

The malt which is to be dried and cleansed by the machine being previously deposited on the cooling granary, is first placed in the receiver. The bottom of the receiver is made of perforated plate iron, or of metallic cloth, and the heat is brought under it through a pipe provided with a valve. The receiver moves round its axis, and is turned until one of the openings corresponds with the funnel or hopper J, by which the warmed malt prepared in the receiver runs into the machine, and falls on the plate iron disc or sheave K, fig. 2. The discs K are fixed by the rings L to the tube R, fixed itself on the axis M, by means of the cast iron pieces. There are five similar sheaves on the same axis at equal distances from each other, and turning in five funnel-formed baskets N, the lower part of which, as well as the upper part of the top basket, are composed of metallic cloth, or of perforated plate iron. The covers O of the lower baskets are made of plate iron, and have two openings covered with metallic cloth. The sheaves K are put in motion by the axis M, and are provided with the small wings which serve to project the malt or other produce against the lateral partition of the baskets, whilst the ventilation that results from it drives the moist air through the openings. Small iron plates fixed under the sheaves serve to separate the malt whilst descending into the baskets, and the large ventilating wings U serve to distribute in an equal manner the heated air on the malt that descends, and so drive away the moist air which collects in that part of the baskets. The same operation is repeated in each basket, after which the malt is conducted by the spout or hopper V to the elevator W, which brings it again to the upper sheave K. As soon as the malt is sufficiently dried, the valve X is lifted in the direction marked by the dotted lines, and this compels the malt to fall into the tube Y, through which it is carried to any place near the machine. The machine may be composed of a greater number of baskets, and their dimensions vary according to the locality and the work to be produced. The baskets N, which are independent from each other, are eccentrically suspended by the rods *b*, fig. 1 (in form of hinges), at the supports C of the machine; their vibrating or shaking motion, which is to make the malt descend in the baskets, and to cleanse it, requires to be stronger on green malt with its radicles than on the drier malt from which the radicles have been removed, and this force is regulated by placing the eccentric thumbs *e* which produce the shakings at different depths by means of the screw E, which brings, as desired, the axis *a* up and down, so as to make, as necessity requires, the points *m* correspond with one of the three thumbs, fig. 1. The projection of the malt by the centrifugal power against the lateral partitions of the baskets makes the radicles separate from the grain, whilst the vibration as well as the ventilation expel the same, as well as all other impurities, out of the machine through the metallic cloth.

The machine is made entirely of iron, and placed in a narrow space of brickwork or masonry supporting a plate-iron roof or cover, whilst in the lower masonry of it is a small oven for coke. The heat is applied to the machine through the tube R, fig. 2, from whence it passes through the openings *a* under the sheaves into each basket. The degree of heat is regulated by the damper or valve *q*, fig. 2, for allowing a more or less rapid desiccation, and to appropriate the same exactly to such qualities of malt as required to produce the different sorts of beer, or as required for other purposes. The machine is put in motion by the pulley *h* fixed on the shaft *g*. The conical pair of wheels *i i* transmit the motion to the principal shaft M, whilst the conical wheels *k k* transmit it again to the vertical shaft *d*, bearing the thumbs *e* and the wheels *l l* to the elevator W. The hopper V, fig. 2, suspended in the arm W, receives the motion from an eccentric *n*, fixed on the shaft *g*. All the parts of the machine that require to be greased or oiled are at the outside of the masonry. If instead of coke it is desired to heat with coal, wood, or turf, and that a chimney becomes necessary, the said chimney is passed through the chamber of the heated air, in order to give off in it the heat of the smoke and of the other products of the combustion.

A new gunpowder was tried at the late Frankfort shooting-feast, apparently with success. Its merits are, a lower price, a less weight, a more effectual action, than the general powder, to which a more important merit is added — that after thirty shots it left the barrel as clean as it was before firing. Its colour is yellowish brown; it is granular, and looks like decayed wood ground small. The inventor is a Prussian artillery captain in Spandau; and his invention is being tested by the Prussian Government.

RIFLED CAST-IRON SERVICE GUNS.

In the Mechanics' Magazine of the 8th inst. it was promised that some further remarks should be made in regard to a pamphlet then just published by Mr. Bashley Britten, upon the Armstrong Gun, as compared with Rifled Cast-iron Guns made on Mr. Britten's system. That promise it is now intended to redeem. Mr. Britten's pamphlet is addressed to the Right Hon. William Monsell, M.P., Chairman of the Select Committee of the House of Commons, on "Ordnance," but it contains matter of deep interest to all who have considered the question of the best form and materials employed in the construction of guns. Without giving our adhesion to all that is advanced by Mr. Britten in his "Letter," it may be permitted us to say that he does advance therein arguments of considerable weight in support of his own views, and that they deserve, therefore, the respect of those who value the opinions and deductions of practical men.

Mr. Britten commences by stating that, since the years 1854–5, he has been constantly urging "the great importance of proper steps being taken to determine the question whether the service cast-iron guns may not be rifled with advantage." It is not, however, his purpose, he says, to maintain "that cast-iron is the best material for the construction of large guns." What he would urge is, that "as the country is possessed of an enormous supply of guns of that material, and representing property of a vast amount, it is not wise to allow them to continue in a less efficient state when by a small expenditure it is possible to improve largely their efficiency." The writer of the "Letter" believes that it is possible to rifle any gun without materially weakening it, and to make it more efficient than a smooth bore without increasing the strain upon it. This proposition is certainly somewhat startling, and if absolutely true it is of the greatest possible importance. Let us see, therefore, by what kind of evidence Mr. Britten endeavours to sustain it. After admitting, as perforce he must admit, that "in recent experiments against armour plates it has been proved that smooth-bore guns are more efficient, at short ranges of 200 yards, than any Armstrong rifled gun that has yet been tried," he asks whether the rifled guns so used have been "the best adapted for the work?" It is clear, indeed, that upon the answer to this question the whole subject hinges. It is well known, says Mr. Britten, that "the force of impact from a projectile depends in a far greater degree upon its velocity than its weight. In the Armstrong gun, however, high degrees of initial velocity, and velocity at short ranges, are known to be sacrificed, in order to employ a long, heavy projectile which shall have a better sustained velocity for long range. Such rifled guns, therefore, are not adapted for hard hitting."

There is no room to dispute this statement, because its truth has been demonstrated over and over again. It does not, nevertheless, militate against rifling guns under any or all circumstances, and in confirmation of the fact that rifling may be advantageously employed upon service cast-iron guns especially, we have the following tabulated results of experiments made in this direction under the superintendence of Mr. Britten himself. The guns used in these experiments were:—

Two	9-pounders,	of 17cwt.	rifled	in	full-sized	bore	of	4·2in.
Three 32	"	58	"	"	"	"		6·375in.
One 32	"	56	"	"	"	"		6·41in.
Three 68	"	98	"	"	"	"		8·12in.

These were fired as follows:—

		Fired in	Projectiles of about	Rounds.
Two	9-pounders	1855	15lbs. each	54
One	32 "	1856 to 1861	50lbs. "	500
One	68 "	1860 to 1861	90lbs. "	300
Two	68 "	1860 to 1861	90lbs. "	10 ea.
Two	32 "	1860 to 1861	50lbs. "	10 ea.
One	32 "	1860 to 1862	50lbs. "	1,100

Nothing was done to strengthen these guns, and the rifling consisted of "merely a few shallow grooves planed out of the bore, about $\frac{1}{12}$in. deep, leaving broad lands between the grooves of about 1¼in. to 2in. wide, so that in firing common round shot from them the rifling was not injured."

It is on official record, indeed, that none of the guns so tried sustained any damage from the operation; and Mr. Britten certainly is only asking a reasonable question when he says, "ought not proper steps to be taken" for further demonstrating the value of his system, or for the purpose of proving its inutility?

We have thus put before our readers the broad and palpable issue upon which Mr. Britten desires to be tried, and it seems to us that the Government is bound to listen to his request.

The "Letter" proceeds with a transcription of trials made at the practice range, at Shoeburyness, with smooth bores and rifled guns, and a careful analysation of the result is given. Then follows a comparison between the Armstrong gun and the rifled service gun. This is of an instructive and highly interesting character, but space forbids our transference of it to our pages. Mr. Britten, however, confirms in the strongest possible manner the statements which we have from time to time been compelled to make in reference to the official favouritism evinced towards Sir William Armstrong. "In 1860," says the author of the pamphlet before us, "I was informed by the Secretary of the Ordnance Select Committee at Woolwich, that a recommendation should be made by that body to the War Office, to the end that a gun of strong material should be prepared for the purpose of testing my system, with the muzzle-loading shunt system proposed by Sir William Armstrong, but, for some reason that I am at a loss to account for, this recommendation was never made." Mr. Britten, therefore, is "one more unfortunate" who has had to work out his invention in the face of difficulties and restrictions.

He has met but small encouragement at the hands of those whose duty it is to examine all plans fairly, and to act impartially towards all whose practical ability and talent have led them to suggest improvements. If Mr. Britten has been able to show such good results under the most unfavourable circumstances, what might he not have effected by the friendly aid of the Government? Bitterly but most justly does he say that "the Armstrong guns represent a system which has been rendered as perfect as it is capable of being rendered, by the trial of countless changes, the command of unlimited resources, and the assistance of the combined talent of the chief military and civil engineers of the country."

We must, in conclusion, advise all who are anxious to form exact opinions upon the merits of the various systems of gun manufacture at present in force, or in embryo, to read for themselves the pamphlet of Mr. Bashley Britten. It is impossible for them to rise from its perusal without having increased materially their stock of information, and we should have felt ourselves deserving of censure had we omitted further commending it to public notice. The pamphlet is to be obtained at 39 Charing Cross, and its very small cost is one of its least recommendations.

THE NEW CUMBERLAND WAR-SHIP MODEL.

We, some time ago, recorded the fact that our townsman, Mr. John Kennedy, was preparing a model of his invention for obviating the difficulties of steering such mammoth naval architecture as the Warrior and the Great Eastern, and we have now pleasure in announcing that the model has been completed, and that it has been placed at our office for public inspection.

It is a very beautiful model, and will doubtless attract the greatest attention wherever exhibited. It has already been seen by many persons, and those interested in such matters had better avail themselves of the opportunity for seeing it at the earliest moment, as the model will shortly be removed to London.

The principal characteristics of the model are the application of the double after-ends, a device in naval architecture which was ventilated some time ago in our columns by the inventor, and which then attracted so much speculation. This principle is intended to obviate the difficulty which has proved such a defect in the steering of large ships, and, in conjunction with the entirely novel screws which Mr. Kennedy has invented, does certainly seem very likely to attain the object aimed at. The screws are of an entirely unthought-of mould hitherto, their design being to give an immense bite upon the water, and to avoid that slipping which takes place under the present form of screw, and causes such a waste of power, and consequent loss of time and speed.

To look at superficially, the form of the ship is admirable, but the connoisseur will at once single out for observation the form of the bottom, which is designed, not only to assist the speed of the vessel, but also to give her the greatest steadiness. The form of the bow will also attract attention: it is of an entirely new character, the idea being taken from the form presented by the head of a fish, and this coupled with the screws, which will act as the tail of a fish, is expected to give the vessel very extraordinary sailing qualities. The peculiar form of the bow would, if adopted on a war steamer, prove most formidable as a ram, and, in conjunction with the almost illimitable power which could be given to the screws, would constitute a vessel capable of annihilating almost any vessel she might be brought in collision with.

In applying his inventive genius to the question of motive power, we are told that Mr. Kennedy has made some surprising discoveries, and, although scarcely yet developed, his plans will, probably, when worked out, make a very close approach to a practical solution of the difficulty of realising perpetual motion.

His discovery of the means of cleaning, or rather of preventing, the fouling of ships' bottoms is also of great importance; and, certainly, if Mr. Kennedy can accomplish what he is perfectly confident he can, namely, a means for keeping the bottoms of our iron ships clean, he will have removed a great and fatal objection, inasmuch as iron vessels will then be applicable for long voyages, for which their present unfortunate tendency for fouling almost entirely unfits them. This would, indeed, be a great desideratum, and would open out a vast field for the use of iron ships.

The model has been made at Messrs. Kennedy's ship-building yard, under the immediate superintendence of Mr. John Kennedy, the inventor; it has been finished in first-class style, having been subsequently painted, and the screws gilded, &c., by Mr. Croasdale, coach-builder, of this town. Taken altogether, she will be an object of interest to anyone; but to those more particularly who are able to form opinions of her several points, she must present features of the greatest interest and speculation.

Having been brought to our office yesterday, this model of the new Cumberland war-ship has already been inspected by a large number of our townspeople, many of them gentlemen competent to express an opinion upon her form and general aptitude for the uses to which the design is meant to be applied; and while all have agreed as to the beauteous character of the model, simply as a model, they have not been few who have expressed decided opinions favourable to Mr. Kennedy's views of naval architecture, and not less strong hopes that he may ultimately be rewarded with such success as shall compensate him for the study and labour he has bestowed upon the subject, and confer honourable distinction upon his native town.—*Cumberland Pacquet.*

A method of extracting alcohol from coal-gas has been discovered at St. Quentin, France, by a young chemist named Cotelle. The report of this discovery created a sensation among the manufacturers of the north, and large sums are said to have been offered by various parties to the inventor for his patent. One company is said to have offered a very large sum for the patent, but no reason is given why the inventor did not accept so advantageous an offer. The *Progrès de l'Oise* asserts as a matter of fact that a joint-stock company was formed with wonderful rapidity, with a capital of 400,000f., to carry out the patent. The inventor announces that he can sell his alcohol at 25f. the hectolitre, while the most inferior spirit produced from other articles is selling for 75f. the hectolitre.

AN IMPROVED METHOD OF LAYING WOOD FLOORS.

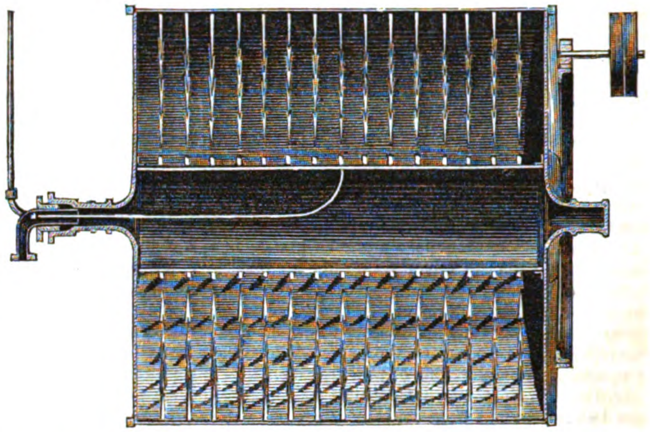
Mr. Robert Bellis, of Chester, builder, has recently patented "An improved method of laying wood floors." The invention consists in fixing, at one side of the joists on which the floor is to be laid, angle-iron, one face of which is made to project from the joist below the level thereof; and in inserting into the underside of each deal or board composing the floor, T-headed screws, one arm of which, on the boards being laid, becomes engaged under the projecting flange of the angle-iron. The ends of the boards are wedged up against the side of the room or building being floored.

Fig. 1 of the accompanying drawings is a section, and fig. 2 is a plan of the underside of so much of a floor as will be necessary to illustrate the manner in which the invention is carried into effect. *a a a* are the joists, to which the angle-irons *b b b* are secured by screws, as shown in fig. 1, or otherwise; *c c c* are the T-headed screws, screwed into the underside of the boards, the heads of which become engaged under the projecting flange of the angle-iron as shown; *d d* are the wedges inserted between the ends of the boards and the side or end of the room. *e* is a skirting for hiding the wedges. Though T-headed screws are recommended as being most convenient, yet screws with one shoulder instead of two may be employed.

The above mode of laying wood floors will be of advantage to architects and builders, inasmuch as by adopting this method the joints, through the shrinkage of the boards, can be easily closed. They can be taken up for the purpose of laying in gas, water-pipes, or bell-wires, at any time; and as nails are not required in the fastening, the floors will be equal to a dowelled one, and much cheaper.

The boards need not be laid until the ceilings and plasterings are finished, as the fastenings are T-screws and angle-iron, screwed to the joists.

SAMPSON'S APPARATUS FOR DRYING WOOL.



SAMPSON'S APPARATUS FOR DRYING WOOL.

This invention, by Mr. E. B. Sampson, of Ham Mills, Stroud, has for its object improvements in apparatus for drying wool and other fibres and substances. For these purposes a rotating vessel or chamber is employed, by preference of a cylindrical form as represented, though the shape may be varied. The rotating vessel or chamber has two ends or covers, through the centres of which the axes of an internal heating chamber or vessel pass. The ends or covers above mentioned are formed with holes or openings to allow steam or vapour from the wool, or other fibres or substances (such as feathers and seeds), within the vessel or chamber to pass away freely, and it is also preferred that holes or passages should be formed for the same purpose in the revolving chamber or vessel.

It is desirable, that after provision has been made for the free passage away of steam or vapour, the rotating vessel should be as close as may be to retain the heat therein.

In order to introduce and remove the wool or other substances into and from the revolving chamber or vessel, part of the periphery is made to open. Within the revolving vessel or chamber there are rows of projecting teeth radiating towards the centre, or other provision is made in order that the wool or other substances may not slip towards the lowest part of the vessel or chamber as it revolves on its horizontal axis. The internal central vessel is preferred to be cylindrical and heated with steam, though this form is not essential, and the mode of applying heat thereto may be varied; it is also desirable that this internal vessel should revolve so as to insure that the wool or other substance when it falls on to the heating vessel shall slide therefrom on to the lower part of the rotating vessel or chamber. If desired, the rotating vessel or chamber may be made of such form and construction as to admit of its being heated, and thus by its heat also contribute to the drying of the wool or other substance. By these arrangements the wool or other fibre within the rotating vessel or chamber will be continually raised up to the highest position, and then allowed to descend to the lowest position through the heated atmosphere of the chamber and in contact with the heated surface.

On the interior of the revolving chamber or vessel are parallel bars with teeth projecting inwards, or such teeth may be otherwise fixed within the cylinder. The sides and covers of the cylinder or chamber have openings through them in order that the vapours evolved from the wool or other fibrous substance which is being dried may get away freely from the revolving cylinder. The wool or other fibrous substance to be dried is introduced into the cylinder or chamber and discharged therefrom through the doorway; steam, or it might be heated air or other fluid, is supplied to the interior vessel by the pipe, the end of which is received into a suitable stuffing-box. The steam and condensed water or hot air or other fluid which is used passes away from the same, or from the other end of the vessel, by another pipe, the end of which enters a suitable stuffing box, and the speed of the flow of the heating fluid may be regulated by the cocks on the pipes. By these means the surface of the interior vessel or cylinder is kept constantly heated. The outer revolving vessel or chamber may, if desired, be made double, or of such form as to admit of steam or other heated fluid being used to heat the same, so as to aid in drying the wool or other fibrous substance placed therein. It is preferred that a slow rotating motion should be given to the inner vessel, in order to insure the wool or fibrous substance dropping or sliding therefrom, or the outer cylinder may carry a scraper or instrument to remove any fibres which may rest on the cylinder. Motion is preferred to be given to the outer cylinder or chamber by means of a cogged wheel fixed on the end of the cylinder.

QUARTZ CRUSHING AND AMALGAMATING GOLD.

The Esmeralda California *Star* gives the following description of operating gold quartz at the Pioneer Mills in Esmeralda:—This mill is run by steam power, using a rotary battery and running eight stamps; its capacity with double screens on is to crush four and a half tons per day; without screens, it can crush from five to six. The rock while being crushed is fed with hot water, which causes the amalgamation to work more readily. The pumice passes off through a spout into what are called "Howland's amalgamating pans;" thence into an arastra, and from thence into a precipitating or amalgamating vat, and is then conducted into what are called "Varney pans," which act as mullers, and grind the pumice down to a perfect pulp, when the final amalgamation is completed: this pulp is now greatly reduced by water, and is carried off by a spout and flows over blankets; these latter catch and retain the sulphurets and the finer particles of metal which the amalgamators fail to gather; the blankets are then washed by hand, and the sediment is reduced by what is termed the "Hatch process," which is extensively used at Virginia and Gold Hill. This mill is now crushing rock from the "Wide West" ledge, the owners having a contract to crush 1,000 tons.

THE INTERNATIONAL EXHIBITION.

Class I. — Steel.

(From *The Times.*)

We now take up the subject of steel. Such a complete and, in some respects, marvellous series of specimens in illustration of steel has never been seen before. The opportunity of studying this collection will, it is hoped, be eagerly embraced by all who are interested or concerned in this important branch of manufacture. With a view to the instruction of the general reader, we propose, in the first place, to describe as concisely as possible the properties of steel; and, in the second place, to explain the principles of the various processes by which it is made. We have previously stated that steel is essentially iron containing carbon within certain limits, which cannot be exactly assigned, but which may be taken approximately as half and one-and-a-half per cent. The characteristic property of steel is that of being susceptible of various degrees of hardness by the common and well-known process of tempering. Thus, if a piece of steel be heated, say to low redness, and then rapidly cooled by immersion in water, it is rendered extremely hard and brittle; but if this hardened steel be strongly reheated and afterwards left to cool slowly, its original softness will be restored. Now, in the process of reheating, which we will suppose to be very gently and gradually effected, it will be observed that the surface of the metal will acquire a succession of well-defined tints, beginning with pale straw and ending with deep blue, the former corresponding to the *lowest* and the latter to the *highest* temperature during the reheating process. If pieces of the same kind of steel be heated so as to acquire respectively this succession of tints, and then instantly plunged into water, or otherwise rapidly cooled, they will be found to possess different degrees of hardness corresponding to the different tints. It is in this manner that steel is actually tempered. The philosophy of the subject is extremely interesting, but in this place cannot be discussed. When we reflect that we are able by such remarkably simple means so to modify the properties of the *same* piece of steel as to transmute it into virtually distinct metals, as far as hardness and certain other properties are concerned, we cannot fail to admire this example of the simplicity and ingenuity of nature. Steel is much more fusible than wrought iron, and may be melted in ordinary furnaces, when it is termed cast steel. Steel may be welded to steel, or to wrought iron, under suitable conditions as to quality of metal and temperature.

The fracture of steel is peculiar, and varies with the proportion of carbon and the treatment which the metal may have previously received. It is more or less finely granular, and when produced in the brittle state of the metal may be conchoidal or shell-like, such as is presented by the broken surface of a lump of glass.

We pass on to the consideration of the principles of the various processes employed in the manufacture of steel—a knowledge of which is essential to the right understanding of many of the articles exhibited. Steel was sometimes accidentally obtained in the primitive method of extracting iron in the malleable state direct from the ore; but it would be impracticable by this method to procure steel of any degree of equality. The processes now in operation are founded on two opposite principles — namely, putting carbon into wrought iron, and taking carbon out of pig iron, which, it will be borne in mind, contains more carbon than steel.

Carbon is put into iron in the following ways:— 1. By melting wrought iron with carbon. This is the ancient Hindoo method of preparing the famous "wootz." The principle has recently been revived in this country in making the so-called homogeneous metal. 2. By cementation—*i. e.* exposing flat bars of iron imbedded in charcoal to about the temperature of melted copper during many days. Carbon thus travels into the very centre of the bars; but how this takes place has not yet been clearly explained. This process of preparing steel is an English one; the furnaces are termed "converting furnaces," and the bars of steel produced are called "blister-steel," from their being studded here and there with blister-like protuberances. 3. By exposing rich iron ore to the action of reducing gases, whereby the metal is obtained in a metallic and more or less spongy state, and then melting this metallic sponge, previously impregnated with carbonaceous matters. Cast steel is thus produced, and the process is known as Chenot's. A well-known French metallurgist had at one time an exalted notion of the value of this process, and once declared in our presence, now many years ago, that it would supersede every other, and that by its means steel might be made and sold at 40 per cent. less than Sheffield steel. There was a great hubbub about Chenot's process at the jury of the French Exhibition in 1855, when an attempt was made to procure for it "la grande médaille d'or." Twice was this refused by the jury; but after the departure of the foreign jurors, the "grande médaille" was subsequently granted by the "Conseil des Présidents."

Carbon is taken out of iron in the following ways:—1. By exposing pig iron to the action of a blast of atmospheric air at a high temperature in a charcoal hearth. "Natural steel" is thus formed. 2. By the process of puddling, conducted so as to leave sufficient carbon in the iron to produce steel. Wrought iron is obtained from pig iron by puddling—that is, heating the metal in a reverberatory furnace with free access of air, and working it about until the carbon is burnt out, or nearly so. Now, if steel be only iron containing more carbon than wrought iron and less than cast iron, it is obvious that in puddling the intermediate state of steel must be passed through. But it is only recently that steel has been made by puddling, yet "puddled steel" is now very extensively manufactured. 3. By blowing air through melted pig iron. This is the process of Bessemer, which has excited so much attention of late, and deservedly so. The carbon and silicon are readily burnt out, and a considerable quantity of iron is also oxidised, as is the case in every process in which pig iron is converted into wrought iron. What could, at first sight, appear easier than blowing air through melted iron? An idea is one thing and its realisation in practice is another. Bessemer has had to contend with many practical difficulties, and is entitled to great credit for the ingenuity and perseverance which he has displayed in surmounting them. This remarkable process is probably destined to effect greater changes in the manufacture of iron and steel than many of our ironmasters suspect or would be willing to believe. As a spectacle, there is nothing so startling and, in our view, so magnificent in the whole range of metallurgy. The melted pig iron is allowed to flow from an adjoining cupola furnace into the "converting vessel," which is a circular vessel of iron coated internally with a refractory lining of silica. Several jets of air are then blown in at the bottom and bubble up through the metal. For a time all goes on quietly, but the temperature gradually increases, and at length a volcanic eruption in miniature suddenly occurs, melted scoriæ being projected on all sides with great violence, and which, if allowed to escape, would inflict serious mischief on any unhappy bystanders. But soon all is again tranquil, and the chamber contains malleable iron in a state of perfect liquidity. This may be tapped out into moulds, and, with special precautions, drawn out into bars, &c.; but it is apt to be cellular and unsound,—defects which Mr. Bessemer has had great trouble in overcoming, if even now he has thoroughly succeeded. Steel is made by introducing into the melted iron in the converting vessel a given quantity of spiegeleisen, containing a known percentage of carbon; and so steel may be produced with any required proportion of carbon. The spiegeleisen dissolves in the iron like sugar in water, rendering the metal more fusible and very liquid. Unfortunately, in the Bessemer process, when pig iron containing phosphorus is operated on, this injurious element is not separated in a sensible degree, as is the case in the process of puddling; so that only those varieties of pig iron which are free from phosphorus, such as hæmatite pigs, &c., can be advantageously used. The Bessemer process is now carried on by two firms at Sheffield—his own and the Atlas works, and, if we mistake not, also in the North by the Weardale Company; and that it should have succeeded in establishing itself at such a stronghold of prejudice as Sheffield augurs well for its final success. The Sheffield people still maintain that good steel for cutlery cannot be obtained by Bessemer's process. We have made particular enquiry on this point, and have received most positive statements on the subject from some steel-makers of vast experience, who, we are sure, are not under the influence of prejudice. But all men are liable to mistakes, and time will soon show whether these gentlemen are correct or not in their judgement. It seems pre-eminently adapted for India, where suitable pig iron may be made with advantage, and where, owing to the heat of the climate, it is especially desirable to avoid the laborious work of puddling. Indeed, it is already in operation at the Porto Novo Works, Madras. Mr. Bessemer introduced his process in 1855. It was received with approbation by some ironmasters and with contempt by others. We have reason to know that certain firms wished to possess themselves of it, in order to hold it *in terrorem* over their puddlers, who have not always shown themselves either the most tractable or the most reasonable men in the world. May Mr. Bessemer live to acquire that fortune which should be the just reward of his invention; and when he has got it, may he, unlike many other successful inventors, have the wisdom to keep it!

In addition to the processes last described, it is necessary to mention others which are also represented in the Exhibition. There is the method of Uchatius, which consists in melting together granulated pig iron and oxide of iron, when the carbon of the former is more or less burnt out at the expense of the oxygen of the latter, with a corresponding reduction of iron. The proportion should be so regulated that sufficient carbon may be left to form steel. In another and old process scrap wrought iron is melted in admixture with pig iron. The product retains the whole of the carbon, and the relative amounts of the ingredients used must be such as to produce steel. It is requisite for this purpose that the pig iron should be of good quality, and that of British make, except the charcoal pig, is too impure. But Messrs. Price and Nicholson maintain that our refined iron is sufficiently pure to admit of its being employed with advantage in this method of making steel. It should be borne in mind that all steel, by whatever process it may have been produced, is termed *cast steel* after having been melted. The variations in quality of the different kinds of steel in commerce are innumerable, and in many cases the reasons for such variation are quite unknown. They are undoubtedly chemical, but have hitherto baffled the efforts of chemists to detect them. Much attention has, however, of late been directed to this most interesting subject, and there is now some hope that we shall not much longer remain in our present state of ignorance concerning it.

We shall consider the varieties of steel in the Exhibition in the order in which we have briefly described the principles of the various methods employed in its production.

Specimens of wootz in the usual well-known little conical ingots will be found in the Indian collection (Class I.); but there is nothing peculiar about them to demand more than a passing notice. Not so with regard to the so-called homogeneous metal, which has excited much attention of late. It is extremely malleable and tough, and may be placed midway between wrought iron and ordinary steel; it may be regarded as steel containing a low percentage of carbon. This is the metal of which Mr. Whitworth has formed so high an opinion, and there is no doubt that it is valuable for many purposes; but it is difficult to obtain it uniform in quality. Examples of it will be found in Class 32, No. 6,456, exhibited by Shortridge, Howell, & Co. Pieces of tubing formed of this metal are shown flattened down

vertically, which might readily be mistaken for caoutchouc. We have not seen this metal made, but we are informed that it is produced by melting pieces of Swedish iron and carbonaceous matter. In the specification of a patent, No. 2,369, A.D. 1856, it is stated that scale, which falls off from steel or iron during the process of hammering or rolling, is employed in addition to the ingredients in common use for cast steel. Now, if anyone will take the trouble to refer to Mushet's *Papers on Iron and Steel* (1840, p. 525), he will find a description of a metal which exactly applies to the so-called homogeneous metal. The process of manufacture appears to be essentially the same, and was patented by Mushet in 1800 (No. 2,447), who is reported to have sold the patent to a house in Sheffield for the sum of 3,000*l*. At the present time the subject is one of no small importance to our practical workers in iron; and, as many of them may not be aware that homogeneous metal was manufactured so long ago, we subjoin an extract from Mushet's work:—

When iron is presented in fusion to 1-140th or 1-150th part of its weight of charcoal, the resulting product occupies a kind of middle state betwixt malleable iron and steel. It then welds with facility, and, provided the precaution formerly mentioned is attended to, may be joined either to iron or steel at a very high welding heat. Thus combined with carbon it is still susceptible of hardening a little, but without any great alteration in the fracture. It possesses an uncommon degree of strength and tenacity, [and is] capable of an exquisite degree of polish, arising from its complete solidity and the purity of fracture conveyed to it by fusion.

If that be not "homogeneous metal" we know not what is. In these days, when patent monopolies beset us on every side, it is desirable that the utmost publicity should be given to facts such as we have just recorded. Why, the zincing of iron, or, as it is grandiloquently called, "galvanising," which has been the subject of more than one recent patent, and, of course, of much litigation, was practised in France about the year 1740, precisely as it is done at this day; and a description of the process was given by Bishop Watson in his well-known and widely-circulated *Chemical Essays*, published towards the end of the last century. And many other instances might be mentioned of old inventions having been monopolised by modern patentees.

Examples of steel produced by the cementation process will be found in the British and several of the foreign departments; but there is nothing requiring particular comment under this head. Until recently all the steel at Sheffield was made by this process, and Swedish iron has been largely consumed for the purpose. Different varieties of iron are known to yield different qualities of steel, but the knowledge respecting these differences is generally regarded as a trade secret. The prices of Swedish iron vary considerably. Thus, No. 72 in the catalogue sells at 32*l*. per ton; No. 50, at 21*l*. per ton; No. 64, at 16*l*. per ton; No. 49, at from 12*l*. to 14*l*. per ton. No. 21 bar iron is well adapted for gun barrels, and No. 64 for card wire. The Swedish ironmasters affect much secrecy, especially with each other, regarding the prices at which they dispose of their iron. We regret that Sheffield is very inadequately represented in the present Exhibition. We miss the names of some of the chief firms, such as those of Sanderson, Jessop, &c. The reason assigned for this is, that sufficient space could not be obtained to enable them to do justice to themselves, and they declined to exhibit at all. There were 170 applicants for space, but half of them withdrew on finding that suitable accommodation could not be granted. This is a serious matter for Sheffield. She no longer maintains her boasted preeminence, even in common articles of cutlery—such as table-knives, in which she is beaten hollow by the French, and this, too, it is said, with steel of her own manufacture imported into France. In surgical instruments she is also signally defeated by the same invading foe. Before the Exhibition she scouted the idea of a rival; but her eyes are now opened, and we have the best authority for stating that she feels her humiliation, and is resolved to amend her ways. In these days of fierce and incessant competition, a manufacturer must not commit the folly of relying upon a reputation buried in the grave of his ancestors. There are energetic and enterprising men in Sheffield, of whom not the least is the present Mayor, whose magnificent rolled armour-plates we have previously pointed out as among the most remarkable objects in the present Exhibition. Nor should we omit to mention as worthy of special praise the firm of Naylor, Vickers, & Co. It is due to the Mayor to record the fact that he has acted in the most liberal manner to foreign jurors and others in granting them free access to his works, where they have witnessed the Bessemer process on a great scale. Those gentlemen have expressed themselves in terms of warm admiration at their reception, and have returned home with recollections of the Mayor of Sheffield which will not be readily effaced.

Chenot's process has been tried in several localities, and has not, we hear, been found successful in a pecuniary point of view, notwithstanding the brilliant auspices under which it was ushered into the world. There was a great display of the *éponges métalliques* in the Exhibition of 1851; and in the present Exhibition various products are exhibited by the Brothers Chenot, in the French Department, No. 14.

Natural steel continues to be produced on the Continent. The Imperial Works, in the Austrian Department, No. 66, which are the most renowned for the production of Styrian steel, exhibit natural steel and cast steel made from it. They manufacture neither puddled nor cement steel. Specimens of natural steel will be found in the Italian Department, Nos. 52–71. It is derived from spathose ores, and is produced by the method known as the Bergamasque.

The manufacture of puddled steel is now largely developed on the Continent; but in Great Britain it has not yet made much progress. Mr. Clay, of the Mersey Works, was the first to introduce it successfully into this country. We have seen it made within the last three years in South Wales. Considerable skill is required in the management of the process, and under any circumstances it is difficult, not to say impossible, to produce steel of uniform quality, even in the same operation. In the Austrian collection are numerous examples of puddled steel, among which may be mentioned the following:—No. 37, Count Meran's Ironworks, Krems, Styria, interesting from having been produced with raw lignite as fuel, which contained 25 per cent. of water and much ash; No. 35, Francis Mayr's works, Leoben, Styria. The examples of this kind of steel are so numerous in some of the foreign departments, that to enumerate them is quite out of the question. In Prussia the manufacture of puddled steel is largely carried on, and examples of the metal, especially in the form of rail sections, are shown in the Zollverein collection. We may notice the puddled steel of the Limburg Company, Westphalia (No. 779), as puddled steel was first made in Germany at these works. The steel is reported to be of excellent quality. In the Swedish Department, Zethelius (No. 69) exhibits puddled steel, produced with wood as the fuel.

We now arrive at the consideration of one of the most extraordinary and most important collections in the Exhibition, the like of which has never previously been witnessed: we allude to the truly magnificent display of Krupp's cast steel. The special points of interest are the wonderful soundness and the enormous size of the castings; and in these respects he is so far in advance of all other producers of cast steel that it will be extremely difficult to approach, much more to overtake, him. Krupp affects considerable mystery in his processes. He rejoices in astonishing the world by the magnitude of his operations; and, like many others, who have far less reason for self-gratulation, he is not inaccessible to the charms of popular applause. He has printed a handsome series of plates of various objects of his manufacture, which is prefaced by four photographic views of his works in Essen. They are evidently of large extent, and are reported to occupy, one way or other, 180 acres of ground. It is stated that he employs puddled steel, which is broken up, assorted, and re-melted in crucibles. This variety of steel does not appear to be adapted for cutlery. He consumes all the spiegeleisen produced by Müsener & Co. It is affirmed that there is a great consumption of plumbago and leather parings at the Essen Works. Each crucible is said to contain 70lbs. of steel, and the furnaces in which they are heated vary much in dimensions, the smallest holding two and the larger twenty-four crucibles. When a large casting is required, the organisation has been carried to such a remarkable degree of perfection, that at a given signal all the crucibles needed are ready to be taken out of the furnace at the same time. Their contents are poured with the utmost rapidity into a large reservoir, and from this the metal is cast. By this means, as in bronze-founding on the large scale, homogeneity is attained. The apparatus for working the steel is the most gigantic yet constructed. There is a steam-hammer weighing 50 tons. The anvil face weighs 185 tons, and cupola furnaces were built expressly to melt this large quantity of metal. The largest casting in the world is the great bell at Moscow, reported to weigh 192 tons; but it cracked in cooling, and was never removed from its birth-place. Krupp's anvil rests on eight blocks of cast iron, weighing from 125 to 135 tons each, and making a total weight of 1,250 tons of cast iron! This solid structure of iron is supported on a wooden foundation 40ft. square. The mould for casting steel solid should be constructed so as to avoid the presence of all angles, of which the inevitable effect would be to cause a lodgement of the air, and consequent unsoundness, due to bubbles. Vent-holes will not suffice to remedy this evil, as they become so soon stopped up by the rapid solidification of the steel that the air has not time to escape. The largest casting exhibited by Krupp in 1851 weighed 2¼ tons, and the largest in the present Exhibition weighs 21 tons. It is in the form of a solid cylinder, about 9ft. high and 3ft. 8in. in diameter. It has been broken across to show fracture. We have inspected the fractured surface over and over again, even under a good lens, and we have failed to detect a single flaw. The largest casting Krupp ever made weighed 25 tons. Now, when we reflect that this enormous mass of metal is melted in comparatively small crucibles, we get an idea of the perfect organisation requisite to have every crucible ready, and the pouring effected at almost the same moment of time; and it is in this organisation that we are disposed to think one great merit of Krupp consists. A large rectangular ingot, weighing 15 tons, is exhibited; it has been broken across in eight places to show uniformity of quality and structure; it was cast cylindrical, and reduced afterwards under the hammer to the rectangular shape. Krupp exhibits shafts, rolls, railway tires and wheels, locomotive axles, and guns. There is a good catalogue in German, illustrated with a photograph of the various objects in the collection, and there is also a price list of the cast-steel guns. A finished gun of eight inches calibre, turned, bored, and rifled, without breech-closing apparatus, is advertised at 975*l*. Among the plates in the large series previously referred to, we notice drawings of locomotive axles supplied to some of our largest railway companies, and crank axles of marine engines supplied to some of our most celebrated marine engine-makers. We congratulate Krupp on the preeminent position which he occupies in the world as the producer of the largest and soundest castings in steel, though not on the site which he occupies in the Exhibition. Whose fault is this? But tallow, toys, and sweetmeats evidently stand high in the estimation of Her Majesty's Commissioners. In the vicinity of Krupp's Works is the smaller establishment at Bochum. We are informed that the processes here adopted are the same in all respects as at Krupp's, and that access to the Works is liberally granted by the proprietors. The large steel bell, not far from Krupp's collection, was cast at the Bochum Works. Steel cannot be compared with bell-metal for quality of sound, but is a cheaper material.

Bessemer makes an admirable display, and has certainly no reason to complain either of want of

space or of obscurity of position—an exceptional case. He exhibits both iron and steel produced by his process, and specimens illustrative of the quality of the metal, as shown by hammering, punching, bending, twisting, stamping, rolling, drawing into tube and fine wire, turning, polishing, &c. A rail is shown, 84lb. to the yard, which may be supplied at 13*l*. per ton. The tensile strength of the Bessemer steel is great, and the metal is now obtained of very uniform quality. Out of 28 pieces taken at random in one establishment, the extreme of difference in tensile strength was about 5lb. or so. We have already said so much about the Bessemer process, that nothing need be added. It is certainly destined to play an important part in the world, and the inventor has reason to rejoice at the success which he has achieved, though he never received a professional education according to the orthodox notions of existing ironmasters. In the French Department, Jackson, Son, & Co. (No. 4) exhibit steel objects made by the Bessemer process. The Swedes have sent both iron and steel made by this process. The large tire is of Bessemer iron. Bessemer steel will be found under the following numbers:—No. 31, Kloster Works, Dalecarlia. At these works are the largest charcoal blast furnaces in Sweden, each producing about 100 tons of pig iron weekly. No. 73, Carlsdal Works, Nericia. No. 75, F. Göransson, Gefle, who was the first to introduce the process into Sweden. Many difficulties had to be encountered, and great expense incurred. Göransson is reported to have effected several improvements. No. 56, Siljansforss Ironworks, Dalecarlia. The process has not yet made its way into Austria. The Prussians have tried it, but failed, and assign as the reason the unsuitable quality of the pig iron employed.

The process of Uchatius excited some attention a few years ago, especially in London. It has been tried but not adopted in this country, for two reasons—first, the difficulty of obtaining uniform results; and, secondly, the high cost. Samples, however, of Uchatius steel are exhibited in the Swedish Department, No. 65, Ulff, Dalecarlia. This steel, strange to state, finds a ready sale at prices ranging from 50*l*. to 60*l*. per ton, which are higher than can be obtained for Bessemer steel in Sweden. It is said to be specially good for sword-blades. It is made by melting Bispberg iron ore, mixed with charcoal, in Belgian crucibles. This ore is remarkable for its purity.

Cast steel made by melting together wrought iron and charcoal pig iron is shown in the Swedish Department, under No. 50, Rettig, Gefle. Cast steel, made by melting together wrought iron and *refined* pig iron, is exhibited by Dr. Price, No. 286, in the British Department, Class I. It is maintained that coke pig iron may be sufficiently freed from silicon and certain other impurities by the refining process as to admit of being employed with advantage in the manufacture of this kind of steel. There may be more in this method than is now supposed.

In the Austrian collection are specimens of the so-called wolfram steel, made by melting together cast steel and the mineral wolfram. The quality of the metal, it was believed, would be much improved by this addition. It breaks with a very fine grain, and is hard and tough. We have learnt on excellent authority that this alloy has not been found successful. We know that a year or two ago some Vienna wolfram steel was submitted to trial by one of the first Sheffield steel makers—a man quite free from the charge of prejudice—and he reported unfavourably concerning it. At present we hear much of the value of titanium and other elements in steel. We have examined this subject with particular care, and have failed to discover satisfactory evidence of the good effects attributed to the presence of such foreign matters.

In the Austrian Department are drawings of Mayr's furnaces for casting steel on Siemens's principle; and we particularly recommend them to the attention of our steel makers. The drawings will explain themselves to those persons who understand Siemens's "regenerative furnaces," of which excellent models are exhibited in the Machinery Annexe. A description without drawings would be of no avail. Lignite is the fuel used, of which three parts by weight are required to melt one of cast steel. In six days between five and six tons are melted in one of these furnaces. Siemens's furnace is evidently founded on philosophical principles, and is, we believe, destined to play an important part in various metallurgical and other operations.

We have now completed our review of the smelting and manufacture of iron throughout the world, so far as they are represented in the present International Exhibition. We have earnestly striven to mete out justice with an impartial hand, neither fearing to censure nor being reluctant to praise. Great Britain has come out nobly, notwithstanding the absence of many of our leading ironmasters. We will not inquire further into the reasons of this indifference. Those who have exhibited are entitled to the gratitude of those who have not. Sweden amply sustains her long-established reputation. Prussia and Nassau have much distinguished themselves. Austria deserves great praise, especially for the liberality and freedom with which she has communicated information. Belgium might have done better. Russia has done well. Italy gives proof of vigorous rejuvenescence. France, remarkable to say, has not even attempted to do justice to herself. Spain presents a melancholy spectacle, thanks to somebody or other. Canada has covered herself with honour. The United States are nowhere. Australia has revealed all her treasures, and excited the envy of the world.

BANK-NOTE SPLITTING.

Mr. Thomas Millard, a native of Bath, now one of the Queen's book-binders, under the librarian at Windsor Castle, has discovered a method of splitting bank notes or any other sheets of paper. By the courtesy of Mr. Gregory, of Bath Street, with whom Millard served his time as an apprentice, specimens of the young man's ingenuity, consisting of a 5*l*. Bank of England note, a sheet of the *Times*, of the *Illustrated London News*, of the *Bath Journal*, and of the *Daily Telegraph*, each of which has been split cleanly and cleverly into two parts, without any rent or tear, have been exhibited to many of our fellow-citizens during the past week. There can be no mistake about the matter, as we have now before us a copy of a leaf of our own *Journal* completely split in two. The separate parts could well be printed on at the back, but the separation of the flimsy paper of the *Telegraph* seems equally complete. The engravings in the illustrated journal are brought out more clearly by the process, and when mounted on cardboard present a strikingly improved appearance. The discovery is applied by Mr. Millard to practical use in print-mounting, and in repairing torn leaves of books, which he can so skillfully manage that the junction of the new and old paper can with difficulty be distinguished. The mounting of old prints upon paper is also so complete, that the specimens we have seen seem impressed upon the original paper. Unscrupulous people would certainly turn this plan of bank-note splitting to profitable account, if they could find it out, inasmuch as the halves could be made as stiff as the whole, the blank parts could be printed in imitation of the original, and the water-mark would of course be perfect. A cotemporary says that "Mr. Millard has devised a method of manufacturing paper that cannot be split, and bankers will probably soon be compelled to make use of his invention;" but this we understand is a mistake. Mr. Millard, to prevent the difficulty which might arise to the Bank of England for having their water-mark left on blank pieces of paper, upon which might be printed *facsimiles* of their notes, suggests a plan for the prevention of the fraud. We are glad to hear that Her Majesty, in consideration of the talent displayed by Mr. Millard in this discovery, has already been pleased to order that he should have an increased salary. We hope his discovery may further lead to his pecuniary advantage.—*Keene's Bath Journal.*

TO CORRESPONDENTS.

Received—W. S., M. A., W. A., J. Le C., J. F., W. R., J. H. T., Col. R., E. L., E. R., Capt. N., W. H. P., R. D.

Errata.—In our article of last week on the "Coinage of 1861," *decimal points*, in lieu of *commas*, should have separated the last three figures of the total weights of gold and silver coined, and the word "*punctuation*" should have been "*peculation*."

Correspondence.

[*We do not hold ourselves responsible for the statements of our Correspondents.*]

THE STRAIGHT LINE *VERSUS* THE WAVE LINE FOR VESSELS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—Mr. Cheverton must be aware that *five years* ago I used precisely the same arguments and illustrations as I have now done. In vol. 67 of the M. M. several references are made to the crank motion; and the very curve itself cannot be formed on any other basis. Mr. Cheverton at that time strenuously attempted to oppose my views with ill-defined logic—without success—with *different arguments to those he now uses* (if, indeed, any tangible argument can ever be found in his letters); and his improper personal remarks then drew forth some severe rebukes, editorial and otherwise. His remarks, therefore, as to my being in a dilemma, and having perplexed and tangled ideas, are contemptible, from the spirit in which they are conceived.

I have hitherto replied to *some* of his personalities; it would be childish to do so to those contained in his last letter.

Mr. C.'s flourish about the theorem of the composition and resolution of forces, and the parabolic path of a projectile *in vacuo*, is amusing.

Having fully refuted all that Mr. C. has *asserted* (not proved) about the straight line, I shall remain silent upon the subject until he is able to bring forward something better than he has hitherto done in support of his straight line. Perhaps I may request, on behalf of myself and your other readers, that he will condense his letters?—I am, Sir,

Your obedient servant,
T. Moy.

1 Clifford's Inn, Aug. 18, 1862.

[We cannot devote any more space to this controversy between Mr. Cheverton and Mr. Moy. Personalities in discussion, by whomsoever introduced, are evidences of weakness.]—Ed. M. M.

Sir,—Messrs. Moy and Cheverton appear hitherto to have had this subject all to themselves, and, for this reason, I hope they will pardon me if I ask for a small space to have my "say" on the subject.

Mr. Cheverton, though well known to possess great practical knowledge of most matters, does not seem to me to have much on this subject, whilst I must compliment Mr. Moy, who, I am informed, has great (though self-taught) knowledge of the subject, on the way in which he has illustrated his remarks.

It seems to me that Mr. Cheverton turns his attention more to the water after it has been disturbed by the passage of the vessel, rather than to the question at issue, viz. how to move the water so that the least power shall be expended in moving it. There can be no doubt that it is very difficult to describe the motions of the water when disturbed by the passage of a ship, but I am perfectly satisfied that Mr. Cheverton's straight-line bow is not the form of least resistance, or one calculated to move the water with the least possible amount of disturbance.

If Mr. Cheverton will take the trouble to stand near one of the piers of the New Westminster Bridge, the cutwaters of which have straight lines, and a tolerably sharp entrance, he will, I think, see that the action of the water shows that even at the low speed of, say, three miles an hour for the velocity of the current, the straight line can in no way be considered capable of performing the duty required of the form of "least resistance." I believe it is generally admitted that nature works on unerring principles; and if Mr. Cheverton admits this, he will soon see that the "wave" or hollow line must give, if properly suited to the circumstances, the most certain results. A year or so since, whilst the river Thames was filled with floating ice and congealed snow, an engineer well known to me, and one who, like Mr. Cheverton, wanted to see everything "straight," was crossing one of the bridges which had the waterway considerably obstructed by piles, when he was

struck by the form in which the ice had accumulated against the piles obstructing the current. The ice, &c., had taken the form of a cutwater to the piling, and the lines resisting the current were hollow or "wave" lines, and there was no disturbance of the water or throwing off of the ice (as was the case in the piers of the bridges with straight or convex lines), thus showing that the current passed with the least hindrance, and the pieces of floating ice continued in contact with this "glacial wave-line cutwater," all the time it was passing.

My friend spent some time in watching this, when it at once occurred to him, that as nature had used a "hollow" or wave line for the purpose of obtaining as little resistance as possible, the hollow or "wave" line must be preferable for the purpose. Next day he called on me and related the occurrence, and agreed with me in considering that if it had been examined it would have shown the proper proportions of length as for a bow, at a speed of three to four miles an hour. I may add, that he has since studied the wave-line theory as laid down and explained by Mr. Scott Russell, and is now one of its staunchest supporters.

I would ask Mr. Cheverton how it is that the ploughs we see are all made with beautiful wave or hollow lines? Surely, if the simple and easily-made straight lines had been found best, they would have been adopted, as here, again, it is a question of least resistance. I have sailed in ships built with straight lines, with convex lines, with hollow lines, and true wave-line ships; and I must say that in none of them do I find so little disturbance of the water, or the ship so well and equally waterborne whilst in motion, as in the wave-line ship. It is a fallacy, and a strong proof of the ignorance of persons of the principles of the wave-line theory, who class every ship, whose bow has a hollow line, as a wave-line ship. I would ask Mr. Cheverton to read carefully and attentively Mr. Scott Russell's experiments and remarks on the wave line, and also Griffith's "Naval Architecture," a work written by an American ship-builder, and I think a little consideration will show him that the straight line cannot do what is required, and a visit to any of the docks in London will show him the strong tendency in all modern ships to employ a hollow line, instead of the straight or convex one.

Your obedient servant,

Chas. F. T. Young, C.E.

7 Duke St., Adelphi, W.C. Aug. 16, 1862.

WASTE GUNPOWDER.

Sir,—Witnessing in your valuable journal your untiring energy to give publicity to all matters relating to warfare, will you kindly allow me space in its columns for a few remarks on a matter which appears to me to be a very serious oversight in the present construction of ordnance and all firearms? What I am now about to point out is, no doubt, a subject which has hitherto been considered too trifling to be worth any deep consideration or proof by experiments; but I am inclined to think that others will, in the end, arrive at similar conclusions to my own. I am led to make these observations from a circumstance which occurred some little time since, while I was on board a steam-ship which carried a pivot-gun, on which being fired, I immediately approached it, and discovered, to my astonishment, the deck strewed with a quantity of unburnt powder, which proved to be a portion of the charge with which the gun was loaded. The deck had, just before the firing of the gun, been swept clean. This immediately attracted a great amount of attention, and I forthwith sought to discover the cause of such a serious waste, which was more than half, nearly two-thirds, of the charge. After much reflection, I was led to conclude that this waste was owing to the position of the vent-hole, placed as is usual at the extreme breech end of the bore; and my opinion has also been deeper impressed on my mind from having seen similar effects to the one above mentioned produced on the discharge of a rifle and ordinary fowling-pieces.

I refer to fig. 1 in the accompanying diagram, which is a longitudinal section of a piece of ordnance with the vent-hole placed, as is usually done, at A. We will now suppose the gun ready to be discharged, and, looking at the position of the vent-hole, we at once see that the fire is communicated first to the back end of the charge; immediately this takes place the gas is generated, and immense pressure follows, which causes a motion to take place whereby the front end or portion of the charge will be pushed forwards with the projectile at a high velocity, so that the fire cannot have time to reach through the whole length of it (the charge) before it has left the mouth of the gun; and so this front or unburnt portion of the charge appears to be blown away.

FIG. 1.

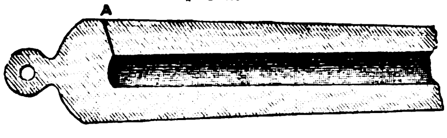


FIG. 2.

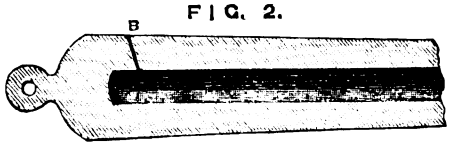

Now for the remedy, which may, perhaps, at once occur to your readers who are convinced thus far. I now refer to fig. 2, which is a similar longitudinal section to fig. 3, with the exception of the different positions of the vent-hole, which now is placed farther towards the mouth of the gun. In this position the vent-hole will come near about the centre of the charge; and on discharging, the fire will be communicated to the body of the charge, and will burn equally through it from the centre towards each end.

The advantages intended to be obtained by this arrangement of the vent-hole, are — 1st, that the fire commencing at the centre will communicate through and ignite the front half before it has left the gun, while the other half will burn backwards, and so continue a greater pressure, which will, in consequence, give the projectile a superior initial velocity, which is the desideratum so earnestly sought for. 2ndly, the whole of the powder being burned, thereby affecting considerable economy.

I much fear that my attempt at describing the supposed cause of the above named loss is very imperfectly done, though I trust sufficiently clear to be understood. It is my intention to conduct some experiments for the purpose of finding out the truth of the best position of the vent-hole, and shall then have much pleasure in letting you know the results. Should any of your readers be inclined to doubt what I have herein endeavoured to set forth regarding the quantity of unburnt powder being blown away, let him take his fowling-piece, or rifle, if he should have one, and load it, and place on the ground under his line of fire something such as paper or a few yards of calico, and, after firing, examine the paper or calico, and he will find it strewed with grains of powder in the same state as they were previous to being put in the gun.

I have the honour to be, sir, yours obediently,

St. John Vincent Day.

Newton Abbot: Aug., 1862.

Gossip.

In the manufacture of tin ware, there is a large waste of the raw material, in the shape of clippings and pieces; and as this waste consists of the two useful metals, iron and tin, attempts have been made from time to time to reclaim each metal separately, with a view to utilise them. The tin, which demands, from its great value, the highest consideration, is first separated from the iron by an acid, and afterwards, by chemical means, restored to the metallic state; but the difficulty has been hitherto to keep the restored tin quite free from iron — the presence of which, though in minute quantities, effectually neutralises the most valuable property of the tin. The great bulk of these clippings, however, is iron, which, by the process of heating and melting, can be reformed into bars; and as a large proportion of the tin-plates used in the manufacture of tin-ware is composed of charcoal iron, a very fair quantity of bar iron might with care be produced; but this can only be accomplished by the introduction of hammers into the furnace itself, whilst the iron clippings are hot, as from their slight substance they would not retain sufficient heat, if withdrawn, for the hammering process in the ordinary way. The subject is evidently worth attention, as many hundred tons of tin clippings must be produced annually in this country, the make of tin plates exceeding 600,000 tons, and the exports having trebled in the last ten years. There are about 6 or 7lbs. of tin to every 100 of clippings, so that in every hundred tons of this refuse material we should obtain (say) between 5 and 6 tons of tin, and perhaps 90 tons of iron.—*P. L. Simmonds on Waste Products and Undeveloped Substances.*

The robbery of Bank-note paper from the Laverstoke Mills is creating an immense amount of inconvenience in all parts of the kingdom; and in some places Bank-notes are positively refused to be taken at all. One natural result of the universal apprehension felt in regard to paper money is, that the demand for coin is largely increasing. The Bank coffers have consequently felt the pressure to a considerable extent, and their contents are rapidly diminishing. Fortunately, that establishment is fully supplied with gold bullion, and the Mint will no doubt be put into immediate requisition, with a view to its conversion into sovereigns and half-sovereigns. It is questionable, however, whether the mechanical capabilities of the Mint are sufficiently great to enable it to meet the sudden and unnatural demand made upon it. The number of stamping presses is far too small, we fear, to contend against the unprecedented strain. At the time of the erection of the Tower Hill Works, in 1810, eight presses were doubtless ample for all exigencies; but it does seem singular, that since that period no increase in their number, or in the speed with which they work, should have been made. The cost of an additional eight, or even sixteen, presses would not be very great; there is ample room for them within the Mint walls, and their existence would make it independent of all panics and pressure, from whatever source arising. We throw out this hint in all sincerity, and trust that it may obtain consideration in the quarter where such consideration is likely to lead to practical results. The large reward offered by the Bank for the discovery of the delinquents who have so successfully appropriated its paper, and no doubt diverted it to the most nefarious purposes, is a proof of the importance with which the crime and its consequences are regarded. It may be trusted that the hand of justice will speedily reach the perpetrators, and that the law will deal with them as they deserve to be dealt with.

A preliminary trial of an automaton semaphore target, the invention of Mr. G. W. Hart, of the 2nd Hants Artillery Volunteer Corps, took place on Saturday, at the practice range of the 5th Hants Rifles, near Portsmouth. Some hundreds of rounds were fired at the target at various ranges, and the results were of the most satisfactory character, the target signalling the effect of each shot instantaneously and correctly in every instance. It transmits thirteen signals — eight outers, four centres, and a bull's-eye. The centres are "high" and "low," left and right; and the signals in each case may be distinctly seen at the longest range, without any fear of being confounded with each other.

In California a powerful gold-mining hydraulic engine is formed by a high head of water conveyed through a pipe, and applied to wash down the face of gravelly hills and banks containing the auriferous deposits. Thus applied, water exerts a tremendous force in levelling hills and exhuming the golden nuggets. At Brandy City, in Northern Sierra, are rich and extensive diggings, which have been hard to work; but several of these powerful hydraulics have overcome all difficulties, and rendered the operations most productive. One of them has a fall of 240 feet through a 15in. iron pipe, and is said to be the most powerful in the State. It will lift boulders or detach masses of cement of a ton weight when brought to bear beneath them.

It is said that ebullition is produced when the globules come in contact with a solid. If, drawn by the currents which heating inevitably occasions, and they strike against the sides of the vessel, there is suddenly formed a bubble of vapour, the globule becomes rather smaller, is projected violently from the point at which it produced this kind of explosion, and then continues floating in the medium. If, when the temperature is above 115° or 120°, a globule is touched with a glass or metal rod, an explosion is produced at the point of contact, a bubble of vapour is disengaged, and the globule rebounds, as though the solid point exercised a sudden repulsion over it. However, all solids are not equally efficacious in producing this change of state; glass or metal rods sometimes fail, but a slender wooden or charcoal stick always incites an immediate and tumultuous ebullition in the middle of the over-heated globules. If a few drops of water are dropped into linseed oil, heated to 105° or 110° in a porcelain capsule, they fall slowly to the bottom of the vessel. The instant they reach it vapour is formed suddenly; the slightly diminished drop of water rebounds, then falls again, causing another disengagement of vapour; again it rises, and so on. The drops of water, while floating in the oil, before touching the bottom of the vessel, undergo no perceptible evaporation; it is only on their contact with a solid that there is a sudden production of a bubble of vapour.

The returns made of the quantity of coal conveyed to the metropolis by railway, canal, and seaborne, still show a very marked diminution. For the present year 755,850 tons 14cwt. of coal have been carried by railway, against 958,713 tons 11 cwt. for the corresponding period of 1861, or a decline of 182,862 tons 17 cwt. The canals show 6,722 tons, against 11,815 tons 15 cwt., or 5,093 tons 15 cwt. less this year than last. The seaborne coal has declined 53,072 tons, the quantity for the present year being 1,932,581 tons, as compared with 1,985,653 tons for the first seven months of 1861. For July last the London and North-Western Railway have conveyed 50,029 tons 1 cwt.; the Great Northern, 25,066½ tons; Midland, 14,588 tons; Eastern Counties, 12,256 tons; Great Western, 7,212 tons; Chatham and Dover, 243 tons 11 cwt.; Tilbury, London, and Southend, 60 tons; total, 109,455 tons 2 cwt., against 119,677 tons 15 cwt. in the month of July, 1861. The receipts by canal for the last month were 534 tons, against 1,690 tons for July, 1861. The importations from Newcastle have been 80,999 tons; Sunderland, 79,724 tons; Hartlepool and West Hartlepool, 57,397; Seaham, 24,959; Middlesborough, 4,427; Blyth, 2,264; from Wales, 9,553 tons; Yorkshire, 3,140; Scotch, 1,364. Of Duff, 1,550 tons; small, 1,313; and cinders, 2,358; making a total of 269,408 tons, against 290,918 tons for July 1861.

On Monday last, the Balloon Committee of the British Association made another ascent from Wolverhampton, Mr. Coxwell was the aeronaut; and Mr. Glaisher represented the Royal Observatory. The ascent was made about two minutes after one o'clock. The balloon contained, when it left the earth, about 65,000 cubic feet of gas. Mr. Prorad, engineer to the Wolverhampton Gas Company, had invented for the occasion an apparatus to test the specific gravity of the gas with greater accuracy than can be attained by any other instrument, in order that the lightest air might be used. The ascent was successfully made, and the balloon descended at five minutes past four, at Solihull, in Warwickshire, about 25 miles from where they ascended, after having attained a height of 4½ miles, where the temperature was 24°, the barometer about 13in., and the dew-point minus 10.

Mr. Roberts, of Millwall, has just completed a self-propelling steam fire-engine, which can also be used as a hoist, or to give motion to other machinery by means of a belt. In size it is about the same as those now in London. Steam has been got to 150lb. per inch from cold water. The water has been thrown to a distance of 176ft. through a 1⅜ jet; it will turn quite round in little over its own length, and has attained a speed equal to 18 miles an hour. Some further trials are to take place in a few days, when we hope to be able to give a fuller description of the machine.

In Paris, mica has lately been applied for preserving, silvering, and gilding decorations in churches and public buildings. The mica is first cut to the desired thickness with a knife, and is then coated with a thin layer of isinglass diluted in water, and the gold or other substance is applied, after which it is allowed to dry. A pattern of copper, with a design cut out on it, is then placed on the reverse side of the mica, and the superfluous parts are removed. The colours are then applied in one or several coats, and the whole afterwards coated with a solution of isinglass and diluted alcohol, by which the mica is rendered pliable. When this is effected, the mica is applied to the object, which is coated with glue or other adhesive material, and allowed to become comparatively dry, after which the surface is made smooth by rubbing it gently with an agate burnishing tool. The value of mica depends on the size of the sheets and their transparency, the clear ruby-tinged being the finest, and the cloudy grey the least valuable.

The new Dudley and Midland Geological Society held its inaugural meeting on Friday last, Lord Lyttleton in the chair; and the inaugural address was read by H. Beckett, Esq., F.S.G., which stated that the South Staffordshire coal field was well known to be rapidly approaching exhaustion, as far as regarded its anciently understood limits; and he felt that it could not be denied that, with a few honourable exceptions, a lack of scientific knowledge had been evinced in its explorations, which had done much to contribute to this sad waste of its invaluable treasures, and, what was of far greater importance—the fearful destruction of human life. After speaking of the great benefit to the district that must accrue from the adoption of a better system of mining, he maintained that the extraneous aid of a society like that might do much to bring about a better state of things. An excursion concluded the programme of the day's proceedings.

The *Stamford Mercury* says that the carpenters are now busy taking down the two windmills west of the Hammond Beck, which were erected in 1768, for the purpose of drawing off the waters from the lands in Bicker Fen. They were found quite inadequate for the heavy falls of rain in the spring of this year; therefore, after a consultation at a vestry meeting, it was determined to ask the advice of Messrs. Tuxford, the eminent engineers of Boston, as to the best means to be devised to prevent the lands from again being inundated. Those gentlemen recommended, instead of the windmills, that an Appold centrifugal pump should be erected, which could be worked at pleasure, by affixing thereto an ordinary thrashing-machine engine, which would throw off the land 5,600 gallons of water per minute, being twice as much as the mills would do under the most favourable circumstances, for when the rain came without wind they could not be worked. It was at once determined by the owners and occupiers of the Fen, which consists of about 1,400 acres, and who doubtless foresaw how it would enhance the value of their lands, to follow out Messrs. Tuxford's suggestion, and resolved to obtain the loan of 500*l.*, to be paid off in four years, which they easily did. They then appointed Mr. J. G. Trimnell to see that the work was properly executed.

At Chester, Conn., there is a mine 300ft. in depth, and extending several hundred yards horizontally into the bowels of the earth. Large masses of a white crystalline substance, streaked with yellow, are obtained in this subterranean artificial cavern; and these sparry crystals are used in large quantities for mixing with white lead paint. This heavy spar is the sulphate of baryta; it is ground in mills, and sold for about twenty dollars per ton. When mixed, weight for weight, with white lead, it is called Venice white; when mixed with one-third of white lead, it is called Dutch white. The purest white varieties are the most valuable, and for certain kinds of painting it is preferred to pure white lead. All lead paints become black when exposed to sulphurous gases; but these vapours have no such effect upon baryta.

The Board of Admiralty has fully approved the model of an improved armour-plated cupola vessel invented by Mr. Turner, master shipwright at Woolwich Dockyard; and one of these vessels is ordered to be constructed. The iron cupola will be fixed instead of movable, 260ft. long, 50ft. broad, and 10ft. deep. Guns will be placed round the vessel from fore to aft, and will be able to sweep the water at such a depression that no gun-vessel can approach. She will be fitted with a ram 3ft. under the surface of the water, 8ft. long; and her rudder-tiller and propeller will be under the water. The ship will carry 26 guns; and her dimensions will be as follow:—330ft. long, 64ft. broad, 25ft. draught, and 8,700 tons displacement.

The piers and abutments of the Divie viaduct, on the Inverness and Perth Railway, which is for carrying the Inverness and Perth Junction Railway across the valley and river Divie at Edinkillie, are now built to the level of the springing of the arches. This will be by far the highest viaduct in the north of Scotland, being more than 100ft. above the river. It consists of seven arches, each having a span of 45ft.; and the total length is 486ft. The piers and abutments are built from stone quarried in the immediate vicinity of the viaduct. The stones for the arching, most of which weigh more than a ton, are brought from Nairn by railway to Forres, and then carted to Edinkillie.

The Cleveland iron district appears to be steadily progressing. New works have recently been started at Stockton, for the manufacture of plates, which are said to have plenty of orders, chiefly for shipbuilding, for which a good price is paid in that district, and for which there is a large local demand in the neighbouring shipbuilding yards. A statement recently published gives the total number of blast furnaces in that district at 84, of which 59 are in and 25 out of blast, and this latter number includes 14 belonging to the unfortunate Consett Company. There are 14 more furnaces in blast than at the beginning of the year; and the district has been prosperous during the whole period of general depression.

Electric Light.—In reference to our notice of M. Serrin's electric light apparatus, we have received a letter from Mr. Henry Chapman, of St. John Street Road, in which he states that he invented and patented, in 1855, an apparatus which would produce a continuous electric light, and had overcome all the difficulties which M. Serrin claims to have been the first to accomplish.

An iron lattice foot-bridge is in course of erection over the railway, from High Street to Forge Street, Crewe.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

Steam Engines, &c., 310, 352, 354.

Boilers and their Furnaces, &c., 333.

Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 323, 335.

Ships and Boats, including their fittings, 314, 315, 328, 330, 341, 343, 348.

Cultivation of the Soil, including agricultural and horticultural implements and machines, 311, 326, 331, 350.

Food and Beverages, including apparatus for preparing food for men and animals, 356.

Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 319, 342, 353, 355, 360.

Buildings and Building Materials, including sewers, drain-pipes, brick and tile machines, &c. *None.*

Lighting, Heating, and Ventilating, 324, 347.

Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 313, 321, 327, 329, 332, 334, 345, 346, 351, 358.

Metals, including apparatus for their manufacture, 349.

Chemistry and Photography, &c., 322, 338.

Electrical Apparatus, &c., 340, 359.

Warfare, &c., 320.

Letter-Press Printing, &c., *None.*

Miscellaneous, 312, 316, 317, 318, 325, 336, 337, 339, 344, 357, 361.

310. C. Calow and J. W. Hirst. *Improvements in slide valves for steam engines and other similar purposes.* Dated Feb. 6, 1862.

This consists in improved modes of equalising the pressure of the steam or fluid on the valve, so that it may be moved to and fro with ease, and at the same time be perfectly tight. *Patent abandoned.*

311. A. C. Bamlett. *Improvements in reaping and mowing machines.* Dated Feb. 6, 1862.

This invention is not described apart from the drawings. *Patent completed.*

312. J. Pitkin. *An improvement in aneroid barometers.* Dated Feb. 6, 1862.

This invention consists in connecting the index hand to a hollow spindle, which carries a toothed pinion at the back of the dial plate, and in fitting a toothed sector to engage in the teeth of the pinion, which sector is attached to a spindle moved by a watch or other similar key at the back of the instrument, in order to set the index hand. The spindle carrying the barometer needle passes through the hollow spindle, to which the index hand is attached. *Patent abandoned.*

313. R. Russell. *Improvements in stove grates and kitchen ranges.* Dated Feb. 6, 1862.

This applies, first, to stove grates and domestic fire-places and stoves generally, and consists in the construction of an ash-pan so as to radiate heat into the room, and to conceal the ashes from view. 2. To kitchen ranges only, and relates to the arrangement of the flues of an ordinary kitchen oven, so as to produce an even and uniform heat over all its surface. *Patent abandoned.*

314. R. Shortrede. *Improvements in the construction of ships of war with armour plates.* Dated Feb. 6, 1862.

Here the inventor proposes to make the plates solid in their defensive front, with flanges all round their inner edges adapted to their being bolted or riveted to each other through these flanges, thereby forming in effect one continuous plate. These armour plates will also be connected to the thinner plates covering the lower part of the hull by the upper row or tier of these lower hull plates having similar flanges, to which the flanges of the lower course of armour plates will be bolted or rivetted. *Patent abandoned.*

315. P. H. Astley. *Improvements in the construction of life boats, applicable also to ships' boats, gun boats, and other vessels.* Dated Feb. 6, 1862.

Here, instead of the bottom of a vessel being formed in the usual way, the same is to have the form of a hollow conic chamber or cavity running from stem to stern of the boat or vessel, the conic cavity having its base enclosed with a perforated bottom. The cone or cavity is built into two outer keels, converging from stem to stern, and enclosed at the bottom, which is perforated, and to which is added a centre keel as an easy means of transit from place to place. Axles and wheels may or may not be attached to the keels. In the centre, and on the top of the cone inside the boat, a stop-cock will be inserted whereby the boat's buoyancy can be regulated with any known and suitable air or pneumatic apparatus; or several conic cavities can be adapted for each vessel; and any suitable means of exhausting or compressing the air contained in the conic cavity or cavities, when on the water, may be adopted in connection with the invention. By these arrangements a vessel will be rendered a safe means of transit. *Patent completed.*

316. M. Henry. *Improvements in obtaining and applying motive power, and raising and forcing fluids, and in apparatus employed therein.* (A communication.) Dated Feb. 6, 1862.

This relates to obtaining and applying motive power by means of fluids; and also to pumping, raising, and forcing fluids. The apparatus employed is constructed on the following principle: If a wheel revolve within a closed chamber,

and have water or other fluid travelling freely through it, such fluid being admitted at the centre and discharged at the circumference, it follows that the dynamical effect of the stream of fluid when issuing from the closed chamber will be to the power that drives the vessel in inverse ratio to the proportion or relation between the sectional area of the delivery opening or outlet through which the fluid issues, and the sum of the sectional areas of the fluid ways or channels in the wheel through which the fluid travels; so that, supposing the delivery opening to be of a certain sectional area, and the wheel to have at its circumference a certain velocity, then the amount of power required to keep up such velocity will be so much the less in proportion as the velocity of the motion of transference with which the fluid moves from the centre of the wheel to its circumference, is reduced. *Patent completed.*

317. E. C. Willis. *Improvements in the treatment of wax and other substances of a similar nature.* Dated Feb. 6, 1862.

This consists in the use of charcoal as a bleaching or purifying agent for wax and analogous substances, such as spermaceti and paraffine. *Patent abandoned.*

318. E. T. Bellhouse and W. J. Dorning. *Improvements in the construction of hydrostatic presses suitable for packing and compressing cotton and other materials.* Dated Feb. 6, 1862.

This consists in a novel arrangement and combination of hydrostatic cylinders and rams, or of a hydrostatic cylinder or ram, with other mechanical contrivances, for compressing and packing into bales cotton, wool, yarn, fibre, hair, &c. *Patent completed.*

319. J. H. Johnson. *Improvements in the preparation of pulp for paper.* (A communication.) Dated Feb. 6, 1862.

Here the inventor makes use of damaged grass, beet root, pulp, and sea-weed, which he steeps in a bath of lime water. These materials are next steeped in a mixture of lime, salt of soda, salt of potass, nitric or muriatic acid, and water. They are afterwards dried, and treated with phenic acid, or with tri-nitrophenic acid, or with carbazotic acid. They are finally bleached by any known process. *Patent abandoned.*

320. J. Tonkin, Jun. *Improvements in the manufacture of gunpowder.* Dated Feb. 6, 1862.

The patentee claims: 1. The manufacture of gunpowder of a compound of charcoal, sulphur, and nitre, or nitrate of soda with vegetable fibre converted into gun cotton, or a substance analogous thereto. 2. The manufacture of gunpowder of a compound of charcoal, sulphur, and nitre, or nitrate of soda with fibre. 3. The granulating gunpowder by a machine consisting of an expressing cylinder or vessel, combined and working in conjunction with a die and endless apron, as described. *Patent completed.*

321. J. D. Dunnicliff. *Improvements in the manufacture of lace or net bonnet fronts and other similar articles, and in apparatus used in this manufacture.* Dated Feb. 6, 1862.

Here, in making bonnet fronts, &c., the lace or net is first goffered by machinery, as usual, before setting the goffered fabric into the band or otherwise, and whilst it is resting on a suitable table or surface the inventor causes an instrument to descend on to the top of the goffers. This instrument by pressing on the goffers, and by moving in the direction of the length of the fabric, throws them into an inclined position, more or less as required, and whilst the goffers are held in the inclined position, the fabric is set or pressed into the band. *Patent abandoned.*

322. R. A. Brooman. *Improvements in stereoscopic albums, books, and cases.* (A communication.) Dated Feb. 7, 1862.

This invention consists in combining a stereoscope with an album, case, or book, in such manner that both may be folded and occupy a small space. For stereoscopic albums, the glass sight-pieces are supported in a frame hinged to the album, which frame, when folded, lies flush with it. There is a plate below which also folds, for preventing the view being too expanded. A compass joint keeps the album open and at the required inclination. The views or portraits are inserted in a frame on the side opposite to that on which the stereoscopic apparatus is fitted. India rubber straps and pins are added for maintaining the sight frame in position. For a stereoscopic book, the sight frame is made as before, and a division plate, hinged to the case, supports it. The sight frame, case, and support, are divided centrally. To close up the book, the support is laid on one side against the case, the sight frame folded on it, with the support for the views on the latter; the whole apparatus is then folded and secured by a clasp. For a stereoscopic case, the views or portraits are arranged to slide on a roller inside and near the edge of the box, at the corners of which elastic springs are fitted supporting a movable plate for carrying the views; the tension of the springs is regulated by means of a ring, through which a rod passes, worked by a screw outside the case, or by any other convenient means. *Patent completed.*

323. J. Lloyd. *Improvements in buffers for engines and carriages on railways.* Dated Feb. 7, 1862.

This invention consists in connecting each buffer-head of every pair of buffers to one end of a rod, the opposite end of which rod is attached to one end of a transverse spring, which is held at its centre in such manner as to allow of its rocking or oscillating when greater pressure is applied to one buffer-head than to the other. Supposing the carriages in a train to be fitted with these improvements, the whole of the buffers will remain in contact, even while travelling round curves, the additional pressure while so travelling on the inner buffers having the effect of forcing out the outer buffers, and of thus keeping both the inner and outer set to the curve in contact. *Patent abandoned.*

324. P. Shaw. *Improvements in lamps.* Dated Feb. 7, 1862.

The patentee claims: 1. Constructing lamps for burning paraffine oil and some other fluids with a vessel for containing the oil, made of glass or other bad conductor of heat, surrounded with a vase or holder capable of being ornamented with any desired design, or of being made of any required shape, all as described. 2. Surrounding the air-tube or rod which passes through the oil vessel with a ferrule or tube of glass, or some other bad conductor of heat, as described. *Patent completed.*

325. H. A. Silver. *Improvements in the manufacture of trays, cases, and other similar articles and bottles, in ebonite, vulcanite, or other hard india rubber.* Dated Feb. 7, 1862.

In manufacturing cases, the patentee forms the top and bottom of plates or sheets of previously prepared ebonite or hard india rubber, and he unites them at the sides and ends, all or some of such sides and ends as may be required, by means of strips or sheets of india rubber and sulphur, prepared for vulcanising in a soft state. He unites the soft rubber to the ebonite by india rubber solvent or cement, and then subjects the whole to the ordinary heat for curing the soft rubber. For trays, the top plate is dispensed with. In manufacturing bottles he makes them in two parts: he forms the lower part in one piece or cup on a mandril, and forms the upper part and neck in a separate piece, and converts both parts into ebonite, vulcanite, or hard rubber, in the usual manner. He thins off the edges of the two parts, places one within the other, and applies both inside and outside, or outside only, a strip of rubber prepared for vulcanising in the soft state, using india rubber solvent or cement as before. He next subjects the whole to the curing process, and when the soft rubber has become converted, he turns down the projecting surfaces at the joint, and the bottle is completed. *Patent completed.*

326. W. E. Gedge. *An improved portable thrashing and winnowing machine and apparatus for working same by horse-power.* (A communication.) Dated Feb. 7, 1862.

We cannot here devote space to the voluminous details of this invention. *Patent abandoned.*

327. A. M'Kenzie. *Improvements in sewing machines.* Dated Feb. 7, 1862.

This relates to the arrangement and construction of sewing machines, which are so arranged that, by a simple mechanical movement, the sewing may be put in the fabric in lines at right angles to each other, or, in other words, the fabric may be sewn longitudinally, and then in the transverse direction, without requiring the fabric to be turned round. The machine is also arranged to sew articles of a tubular kind, like boot legs, or circular seams, with greater convenience than heretofore. *Patent completed.*

328. W. Clark. *Improvements in preserving timber, which are particularly applicable to timbers of ships or other maritime structures.* (A communication.) Dated Feb. 7, 1862.

This consists: 1, in depriving the wood of its sap, and, consequently, of its fermenting properties; 2, in submitting the wood to an artificial desiccation; 3, in singeing the face of the wood, when the work is finished, by a slight carbonisation. To deprive the wood of its sap, it is plunged in soft water, which, being less dense than the sap juices, forces out the latter, and fills all the fibres of the wood in its turn. The wood is dried by means of an apparatus of Messrs. Légé and Henry Piromet's, for injecting poplar and beech woods with sulphate of copper. The wood is now ready to receive a current of heated air, with which a certain quantity of sulphuric acid is mixed, which prevents the formation of fungi on ships' bottoms. A paint composed of sulphur, linseed oil, and boiled oil, is applied to the bottoms of ships. The surface of the wood is charred by a jet of gas. *Patent completed.*

329. H. Macaulay and A. F. Notley. *Improvements in fire guards.* Dated Feb. 7, 1862.

Here a fire-place, or a stove set therein, is arranged to admit of a guard passing into and out from one or both sides, and such guards may be made of wire-work, sheet metal, or other suitable material, and when intended simply to prevent dresses coming to the fire, or the flying out of cinders from the fire, the guard may be of open wire-work, or otherwise of a reticulate character; but when it is intended to be for a shade or other covering of the fire or front of the grate, then the guard may be close, or perforated, or reticulated to a less extent. It is preferred that each guard for a fire-place should be formed into two parts, one arranged to slide in and out on one side of the fire-place or stove, and the other to slide in and out on the other side. *Patent abandoned.*

330. W. H. Bartholomew. *Improvements in barges or vessels suitable for the navigation of canals and rivers.* Dated Feb. 7, 1862.

This consists in so constructing barges that they may be coupled together end to end, there being in the centre of the stern of each barge a projection, which, when several barges are coupled up into a compound vessel, enters a corresponding recess of the stern of the barge in front of it. The steering of the compound vessel is, to a great extent, effected by means of chains. *Patent completed.*

331. H. Brinsmead. *Improvements in apparatus for mowing, elevating, cleaning and dressing grain.* Dated Feb. 7, 1862.

This consists in arrangements for simplifying the operations of mowing, elevating, awning or hummelling, chobbing (that is, removing the calyx or white coat from the kernel), cleaning, and dressing grain, and may be used either in connection with thrashing machines or otherwise, and effects simultaneously the whole of the operations mentioned above. The apparatus consists of a rotary fan having a chob, cleaner, and awner on one or both sides, the moving parts of which the inventor by preference attaches to the shaft or spindle which carries the fan-arms or blades, or to the arms or blades themselves. The fan is fed with air by one or more tubes of any convenient section, communicating with one or both sides of the fan, as may be desired. The grain to be operated upon is introduced into this tube or tubes, and by the current of air therein is moved towards the fan. Between the aperture or apertures for the inlet of air to the fan, and the revolving fan-blades or arms, there is placed a diaphragm formed of perforated plate, wire-work, or other material pervious to the air, but not to the grain, by which the air that has moved the grain is separated from the grain which remains in the chob cleaner and awner. These are placed at the side or sides of the fan or fans, and after operating on the grain as much as convenient, deliver it by their centrifugal action through suitable spouts or shoots at such places as may be desired. When the invention is applied to thrashing machines, the inventor uses the whole or a portion of the current of air issuing from the fan for those purposes. *Patent abandoned.*

332. G. S. Woodhouse. *Improvements in hooped skirts.* Dated Feb. 8, 1862.

Here the lower portion of the skirt is made in the usual way with concentric hoops of metal, or other sufficiently elastic material, the same gradually diminishing in diameter as they approach the waist; these hoops are connected by the fabric of which the skirt is composed, or by other means. The upper part of the skirt is constructed with parallel strips of metal, or other material; such parallel strips, however, do not extend to the front of the skirt, which consists wholly of the fabric before alluded to. In order to render the portion of the framework consisting of the parallel strips more rigid and capable of supporting the weight of the external dress without collapsing or becoming depressed, strips of metal are placed transversely across the horizontal strips, and connected therewith at any desired angle or angles, thus constituting the bustle. *Patent abandoned.*

333. J. Howie. *Improvements in regulating the consumption of fuel in furnaces.* Dated Feb. 8, 1862.

Here the inventor conveys a portion of steam from the boiler in a pipe (a small pipe being preferred) to underneath or into the furnace, and allows the said steam to escape evenly under the bars, when it will pass up through the furnace. The application of steam in this way is suitable for any kind of furnace where there is sufficient heat. *Patent abandoned.*

334. J. A. Knight. *Improvements in washing machines.* (A communication.) Dated Feb. 8, 1862.

This consists in the use of a light barrel, or other vessel, on one end of which is attached inside a circular "rubber board" or corrugated surface, and on the opposite end inside is secured a series of pins or other projections. The machine is supported by two trunnions fixed on opposite sides thereof, the trunnions resting on a frame or stand. By the longitudinal revolution of the machine, the articles to be washed are precipitated from end to end, bringing them alternately in contact with the "rubber board" and pins, so as to secure the desired object. *Patent abandoned.*

335. F. Tolhausen. *An improved system of manufacturing the tyres of railway wheels by hydraulic pressure and steam.* (A communication.) Dated Feb. 8, 1862.

This relates to a novel system for applying pressure to the rolling of the wheel tyre, and to the preparatory shipping of the tyre on the wheel, the object being to render hydraulic pressure more obedient or subservient to the operations, and also to obtain certain advantages both with regard to quality and the cost of manual labour. In order to tyre a wheel, the inventor subjects the iron or steel bar to three distinct operations: 1, winding the bar on a cylinder, the same being seized between a headstock and a hydraulic piston, which shapes the blank or hoop; 2, the hoop is hammered as usual, but he uses a savage with a movable or "universal" mandril, by which the removing operation is greatly facilitated; 3, the hoop is then rolled under an upper horizontal roller, the axis of which is acted upon by hydraulic pressure by means of a hydraulic pressing-box. *Patent completed.*

336. J. Webster. *An improvement or improvements in the manufacture of certain descriptions of nails, bolts, spikes, and pins.* Dated Feb. 8, 1862.

This consists in making nails of the kind used for sheathing ships, bolts, spikes, and pins used in ship-building, securing railway chairs, &c., by forming them triangular in cross-section, and afterwards twisting them slightly in the direction of their length, so that, while no impediment is offered to the driving of the nail in the usual way, it takes more power to draw it again. *Patent abandoned.*

337. J. Carrington. *Improvements in the construction and fitting up of stal's and horse-boxes.* Dated Feb. 8, 1862.

Here the object is to provide stables with stalls or boxes, and fittings of an improved construction, which, amongst other advantages, will admit of being readily removed when required, without defacing the walls of the building to which they are applied; will give increased facilities for flushing drains, and provide an efficient means for accustoming young horses to the bit. The invention is not described apart from the drawings. *Patent completed.*

338. M. A. F. Mennons. *Improvements in the treatment of coprolites and other fossil phosphates of lime.* (A communication.) Dated Feb. 10, 1862.

This relates to a method of treating coprolites and other calcareous phosphates, by which these minerals are converted into assimilable manure, and at the same time are rendered applicable to the disinfection of certain animal products, and to the extraction therefrom of fertilising principles. The nodules or rocky phosphates to be operated on are first pulverised as finely as possible by any suitable machinery, and with the powdered mass is intimately incorporated from six to ten per cent. of organic matter, highly charged with hydrogen and carbon, say, for instance, the pitch or tar produced during the distillation of coal in gas manufacture. The mixture is then calcined at a temperature of from 400° to 500° (Centigrade) in closed and luted kilns, retorts, or other suitable capacities, each containing a minimum of four hundredweight. In this the tary matter is decomposed, the hydrogen unites with the sulphur of the sulphuret of iron, forming sulphuretted hydrogen, which is thrown into the furnace and there consumed. The carbon reduces the metallic oxides, divides the molecules, and assists the conversion of the sulphurets into carbonates, which afterwards pass to the state of oxides, the carbonate of lime especially being converted into oxide of calcium (quicklime). The water and carbonic acid are driven off, and the excess of carbonaceous matter takes their place. When the disengagement of gas ceases (generally in from half an hour to an hour with the quantity above noted), the operation is suspended, the product is withdrawn from the recipient, and placed to cool in sheet-iron dampers. *Patent completed.*

339. M. A. F. Mennons. *Apparatus for the administration of vapour baths.* (A communication.) Dated Feb. 10, 1862.

This invention is not described apart from the drawings. *Patent completed.*

340. J. Dickson. *Improvements in voltaic apparatus and in the production of voltaic electricity.* Dated Feb. 10, 1862.

The discovery upon which this invention is based is that, by raising the temperature of the electrotypes and substances used in the evolution of voltaic electricity, the facility of colouring such electricity from the substances now usually used for that purpose is increased, and, further, that the increase of the electric fluid obtained by this method is such as to render certain cheap and easily procurable materials (from which the electric fluid has not by any means hitherto known been obtained in quantities sufficient to warrant their use in manufacturing) remuneratively available for the purpose of such manufactures. The substances used are iron, zinc, lead, and carbon. *Patent completed.*

341. R. Philp and J. Philp. *An improvement in propellers for propelling ships, boats, and other vessels in water.* Dated Feb. 10, 1862.

This relates partly to the form of the blades, and partly to their relative position on the boss, and is as follows:—The inventors increase the surface of the blades at the outer extremities of their leading edges, while they cut away the

corresponding portions of the delivery edges, so that the horizontal distance between the leading corners of the crowns, when the delivery edges are perpendicular, is greatly increased for the same diameter of propeller and surface of blade over the corresponding distance between the leading corners of propellers hitherto in use, while at the same time the horizontal distance between the delivery corners is reduced as near as may be to a point. The blades so placed spread out laterally on each side until they make but one angle instead of two vertical angles, as in propellers hitherto made (as near as may be), viz. at the delivery corners, as seen by a spectator looking through the propeller from one corner to the other. *Patent abandoned.*

342. J. BUSFIELD and J. EASTWOOD. *Improvements in machinery or apparatus for preparing wool for dyeing and spinning.* Dated Feb. 10, 1862.

This relates to means for producing uniformity of twist in slivers of wool preparatory for the dyeing process, and also for taking out the twist of slivers of wool preparatory for drawing and spinning. The apparatus consists of suitable framing, on which are mounted two pairs of nipping rollers for drawing the slivers forward from the ball, which is placed in a receptacle or cylindrical vessel mounted centrally upon a vertical spindle, to which variable rotary motion is given by a friction wheel applied to the bottom of the vessel, which forms a friction plate. This friction wheel is capable of sliding on a shaft by which it is driven, and receives rotary motion through a train of gearing from the drawing roller. The said friction wheel is moved to or from the spindle or central of the cylindrical vessel by a rod connected to a stud plate or crank fixed on a shaft, to which rotary motion is also communicated by the gearing, and which is so arranged as to produce or give any desirable variation of speed to the vessel. A ball of sliver is placed on the vessel, and the inner end of the said sliver is passed through a central hole in a portable rail placed across the top of the vessel, and thence betwixt one of the pairs of rollers to the other pair, which draws it forward at an uniform speed. If it be required to produce twist in the sliver, then the friction wheel is placed or arranged so as to act upon the outer part or edge of the plate or button of the vessel at the commencement, giving a slow motion thereto, which gradually increases as the friction wheel moves nearer to the centre of the plate. *Patent abandoned.*

343. B. C. PIM and G. FAWCUS. *Improvements in uniting iron plates and in uniting and fixing armour plates on ships and other structures.* Dated Feb. 10, 1862.

This invention consists in uniting iron plates to one another by means of double-shafted keys or rivets, which the inventors drive into dovetail grooves formed in each of the plates to be united. The double shafts are united and form but one piece by means of a web, which, when the parts are in position, comes in the same plane as the seam between the two plates. The grooves may be of the regular angular dovetail, or they may be circular, or of any other suitable form, but of course must correspond with that of the key. When for the purpose of uniting armour plates, and fixing them to any structure, they form one or more slots through the key or rivet at that part which, when in position, will come behind the structure to which the plates are to be fixed, and they insert pins into the said slots. In addition to this means of fastening, or in substitution for it, they sometimes taper off the double-shafted key or rivet into one shaft at the point, thread it, and, after passing it through a hole in the framework of the structure, fasten up by a nut. *Patent abandoned.*

344. L. R. BODMER. *Improvements in hydraulic oil presses.* Dated Feb. 10, 1862.

This relates to certain improvements upon and modifications of the hydraulic oil presses, for which letters patent were granted to the present inventor on Dec. 20, 1855 (No. 2,886). The objects of the present improvements, which are applicable to all vertical hydraulic presses, are to economise labour and time in the working of the press, and to dispense with the bags or wrappers for the seed or other oleaginous matter; such, for instance, as the cocoa-nut, from which the oil is to be extracted by pressure. The inventor prefers the seed holders should be of a cylindrical form. *Patent abandoned.*

345. G. SMITH. *Improvements in shawls.* Dated Feb. 10, 1862.

Here the patentee proposes adding to shawls an extra piece or pieces of the same or other fabric (which, for the purpose of explanation, he terms leaves), either by weaving, sewing, or other means, so that, when the shawl is worn, it may present at the back two, three, four, or any number of separate "leaves" falling within the size of each other externally, and all within the size of the shawl itself, to which the leaves are attached. *Patent completed.*

346. J. DANKS. *Improvements in the manufacture of door-mats and hearth rugs.* Dated Feb. 10, 1862.

This relates to the manufacture of mats and rugs composed of cocoa-nut fibre, or partly of cocoa-nut fibre combined with wool or other material, with a pile face on each opposite surface thereof, so that their surface may be used as the upper surface, and considerable economy with other advantages in use are thereby obtained. For this purpose, in place of using a number of back-chain or warp-threads to each row or series of tufts of piles of which the mat or rug is composed, as is the practice when making door-mats of cocoa-nut fibre with one pile surface, the inventor finds it necessary to use two, one upon which a row of tufts of pile for one surface are formed, and the other for a row of tufts of pile for the opposite surface; and these chain or warp threads, with their rows of pile, being repeated according to the width or length of mat or rug required, are connected together by shoots of weft. *Patent abandoned.*

347. W. CLARK. *Improvements in reflectors.* (A communication.) Dated Feb. 10, 1862.

This relates to reflectors for converging and concentrating the rays of light on one or more parts at the same time, utilising the whole of the rays of reflectors, which are at present in a great measure lost. The improved reflector is formed of a series of reflecting surfaces, the angles of which are calculated so as to direct or concentrate the luminous rays on one or several given points. *Patent completed.*

348. A. MUNCK and H. A. MYHRE. *Improvements in ships' logs.* Dated Feb. 10, 1862.

This relates to that class of ships' logs which have the registering apparatus placed on board, or attached to the vessel, and receive the motion of the rotator placed in the water by a line, and consists, 1, of a particular arrangement of the regulating gear, whereby the inventors bring the line of axis receiving motion from the rotator line in line with the axis of the indicating hands, which are 2, 3, or more, and all concentric the one with the other, like the hands of a clock; on the outer circle they indicate furlongs and miles, by preference up to five miles, on the next from five miles up to sixty miles, and on the inner circle from 60 to 720 miles. *Patent abandoned.*

349. W. CLARK. *Improvements in refining cast iron, wrought and other malleable iron, and in the cementation of iron.* (A communication.) Dated Feb. 10, 1862.

Both lighting gas and coal in the pure state possess sulphureted products, which would combine with the iron, and, as infinitesimal quantities of sulphur are sufficient to entirely change the quality of the iron or steel, it will be apparent that it is highly necessary to remove it. This may be effected by adding to the coal a certain quantity of lime, or carbonate of lime, which, at the high temperature to which the mixture is raised, becomes transformed into quicklime, and retains in the state of sulphuret of calcium not only the sulphur resulting from the distillation of the coal, but also that evolved in the furnace, which always filters in the cementing cases. The presence of the lime prevents an excess of sulphur being taken up by the iron, and also possesses the further advantage of removing the greater part of that which it previously contained; it thus purifies and refines the iron, and renders it more suitable for subsequent connection, and, in fact, enables good steel to be obtained from iron of inferior quality. *Patent abandoned.*

350. W. H. WEAVER and C. GALL. *Improved machinery for agricultural purposes.* Dated Feb. 11, 1862.

This consists in constructing machinery consisting of a suitable frame and appliances, having two or more rows or sets of tines, with these rows or sets secured upon one and the same axis, the ends of which axes are provided with quadrant-shaped pulleys, over and secured to each of which is a chain or rope, which passes the draught bars of the machinery, so that any one row or set of tines or implements is put in action, and that one row or set of tines or implements will thereby be withdrawn from the land, and another put to work, the row or set of implements in work being held in position by the draught of the machine, inasmuch as there is a similar chain arrangement and connecting bar, or other arrangement attached to another similar axis to that first mentioned. *Patent abandoned.*

351. T. FYFE. *Improvements in knapsacks, and in apparatus for supporting them or other suitable burdens upon the shoulders.* Dated Feb. 11, 1862.

This consists in a mode of constructing knapsacks, &c., whereby they are supported upon the back of the wearer by two horns or projections of metal or wood, such horns projecting one over each shoulder, and by certain suitably arranged straps in connection therewith. *Patent completed.*

352. C. BONELL and W. M. SPIRING. *A new or improved rotary engine.* Dated Feb. 11, 1862.

This invention consists of a rotary engine to be worked by steam or other vapour or gas, constructed essentially as follows:—The cylinder of the engine is very nearly, but not quite, circular in cross section, having a slightly elliptical figure. In the interior of the cylinder is a shaft or axis, the said shaft or axis being eccentric to the cylinder, one of the sides of the said shaft bearing against an elastic packing on one side of the cylinder, the said packing being in the shortest diameter of the cylinder. In a slot passing through the said shaft a plate or piston works, the said plate or piston forming a partition or diaphragm across the said cylinder, upon which partition or diaphragm the steam acts. As the steam is admitted into the cylinder between the elastic packing on which the shaft bears and one side of the piston, the said steam presses the piston forwards, causing it and the shaft to perform a rotation. The steam then escapes from the cylinder. A slight depression is made in that part of the cylinder at which the steam enters, so that when one side of the piston is brought over the steam passage, the said piston does not bear tightly upon the cylinder. A small portion of steam consequently escapes past the part of the piston in question, and, acting on the other part of the piston, carries it past what would otherwise be a dead point. The edges of the piston are provided with metallic packing. By the use of an ordinary slide valve the direction of the steam may be changed, and, consequently, the direction of the engine's rotation. *Patent abandoned.*

353. E. SUTTON. *A certain improvement in machinery or apparatus for preparing cotton and other fibrous substances for spinning.* Dated Feb. 11, 1862.

This invention relates to that description of machinery used in the preparation of cotton and other fibrous substances called the scutcher or opener, and is designed for the purpose of extracting dirt and dust therefrom. The improvement consists in the application and use of a perforated door or partition behind the beaters (that is, between the beaters and the exhausting fan), such door extending in a division across the width of the chamber or body of the scutcher. By this means the lighter dirt and dust are abstracted from the cotton through the perforations of the door by the exhausting action of the fan without allowing the filamentous substance to pass. *Patent abandoned.*

354. W. MACNAB. *Improvements in steam engines.* Dated Feb. 11, 1862.

The patentee claims: 1. The causing of the fresh steam in combined high and low pressure engines to give up a portion of its heat to the partly-used steam, substantially as described. 2. The combining together of two pairs of high and low pressure cylinders, with the individuals of each pair acting at right angles, as described. *Patent completed.*

355. W. LYALL. *Improvements in machinery for preparing flax, hemp, and other fibrous substances.* Dated Feb. 11, 1862.

These improvements are twofold, and consist: 1. In placing an additional gill carriage or carriages immediately above the present gill carriages or heads of the ordinary spreading or drawing frame, so as to form one machine, whereby great economy of space, labour, and first cost are judiciously effected. 2. In wetting or damping the fibrous bands or slivers in their progress through the aforesaid machines, thereby making them better adapted to undergo the various processes which finally convert them into yarn. In the first improvement the patentee bolts the sides or standards of the top and bottom carriages together, or they may be cast in one, the bottom carriage being bolted to the usual longitudinal rails, which are again connected by the frame ends. Sufficient distance is left betwixt the upper and lower heads to allow all the parts to work freely and independently. The driving pulleys are placed in a position common to both carriages. The slivers which issue from the top delivery rollers may either fall into their respective cans at once, or pass betwixt the delivery rollers of the lower head into the same can with the bottom slivers. The damping of the slivers is effected by a sponge or other suitable material pressed gently on the sliver betwixt the drawing and delivery rollers, whilst the machine is in operation, but withdrawn immediately on the stoppage of the same by a series of levers in connection with the belt motion. The sponge is supplied with water by an india rubber or other flexible tube communicating with a small cistern, the water in which is kept at the same level, in order to give a regular supply. The cistern is placed in a suitable position to allow the water to gravitate to the sponge, and the supply is stopped by compressing the flexible tube immediately on the stoppage of the machine. The sponge need not be applied to every sliver, but to one or more, and the doubling of the sliver diffuses the wet through all. *Patent completed.*

356. W. WOOD. *Improvements in the manufacture of pomfret or liquorice cakes.* Dated Feb. 11, 1862.

The dough or paste, omitting the liquorice and some other materials, is, according to this invention, first prepared and subjected to heat in a pan; the extract of liquorice and other materials are then combined with the paste or dough on a metal or other suitable table, heated in any convenient manner, such table having one or more rollers so placed that they rest thereon, or are at any desired distance therefrom, and they are either moved upon the table, or the bearings of the rollers may be fixed and the table be continually moved under the rollers. Scrapers are also used to move and turn the materials on the table, so that by the combined action of heat, and the pressure or rubbing of the rollers, the materials are intimately mixed, and at the same time dried to any desired consistency. By the action of a screw or other form of pressure acting with moulds or dies, the cakes are rapidly produced without being handled, and by using a series of moulds or dies, several or many of such cakes are made at the same time, each marked or ornamented on one or both sides by the moulds or dies being properly formed with the desired devices and names. *Patent completed.*

357. J. H. JOHNSON. *Improvements in smoothing irons.* (A communication.) Dated Feb. 11, 1862.

This invention relates to smoothing irons having two faces, and made reversible, so that one face may be heated while the other is in use. According to this invention the iron is heated by gas jets issuing from a pipe inside the iron, such pipe being secured to an end plate which allows the iron to be reversed, and enables it to be locked in its proper position by a spring catch. The jets are surmounted or enclosed by a small chamber covered with wire gauze, whereby the prevention of smoke is effected; a gas cock in connection with a flexible tube is soldered to the outside of the loose end plates above referred to, or a small nozzle only may be soldered thereon, over which the end of the flexible tube is passed and secured, the gas cock in that case being at the other end of the tube, or in any convenient part thereof. *Patent completed.*

358. J. BRINSMEAD. *Improvements in pianofortes.* Dated Feb. 11, 1862.

This invention is not described apart from the drawings. *Patent completed.*

359. R. JOHNSON. *Improvements in welded wires used for telegraphic purposes.* Dated Feb. 11, 1862.

This invention has for its object the strengthening of those joints which are produced by welding, and the maintenance of a continuity should the welding give way. These advantages the patentee proposes to attain by protecting the said joints with a metal covering, and this he forms by winding wire or other such material around the joint, so that, should the welding break, the said wire will still constitute a connection or conducting medium. By a subsequent process of galvanising the whole becomes soldered together. *Patent completed.*

360. G. LINDEMANN. *Improvements in applying gas for the purpose of singeing or dressing yarns or threads and woven fabrics, and for obtaining heat for other purposes.* Dated Feb. 11, 1862.

This invention consists in submitting yarns or threads and woven fabrics to the action of the flame of gas, which is caused to rotate by giving an axial motion to the burner; and the patentee also applies the said revolving flame to surfaces used for drying, or to other purposes where heat is required. *Patent completed.*

361. J. J. M'COMB. *An improved fastening for securing cotton and other bales or packages.* Dated Feb. 11, 1862.

The patentee claims connecting together the looped ends of metal bands, surrounding cotton and other elastic bales or packages, by means of a metal buckle constructed as set forth. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated June 3, 1862.

1676. J. Fincham, Beck Row, Mildenhall, Suffolk, machinist. Arrangement or arrangements of mechanism useful for facilitating the repairing of roads and ways, also applicable to the tilling of land.

Dated July 17, 1862.

2043. M. Kurts, 151 Bishopsgate Street Without. A new or improved material to be used in the manufacture of handles for umbrellas, parasols, and walking-sticks.

2045. H. Appleby, Tavistock Place, Plumstead, Sergeant-Major in Her Majesty's Royal Body Guard. Improvements in armour plates for ships of war, floating and land batteries, and other like purposes.

2047. J. Schloss, Cannon Street, manufacturer. Improvements in pouches.

2049. T. B. Daft, 2 Queen Square, Westminster. Improvements in the manufacture of vulcanised india rubber thread.

Dated July 18, 1862.

2055. J. S. Jarvis, Wood Street, warehouseman. Improvements in shirt collars.

2057. C. A. Day and T. Summers, Northam Iron Works, Southampton, engineers. Improvements in sheer legs.

Dated July 19, 1862.

2059. G. J. Yates and J. W. W. Tindall, Liverpool, chemists. A process of deodorising paraffin, coal, pitch, rock, and other like oils and hydro-carbons.

2061. R. A. Brooman, 166 Fleet Street, patent agent. Improvements in revivifying animal black, in apparatus employed therein, and in recovering a product employed in the revivification. (A communication.)

2063. A. Pratt, Devonshire Place, Wandsworth Road. Improvements in self-capping firearms.

2065. W. E. Newton, 66 Chancery Lane. Improvements in machinery for preparing fibrous substances for combing. (A communication.)

2067. W. Tranter, Birmingham, gun manufacturer. Improvements in firearms.

Dated July 21, 1862.

2070. E. Bazin, Angers, France, engineer. An improved electric railway carriage signal.

2073. A. M. Fell, Auchanhard, Linlithgowshire, manufacturing chemist. Improvements in obtaining or manufacturing sulphate of ammonia and manure.

Dated July 22, 1862.

2077. T. Meriton, Hamburgh, engineer. Improvements in steam-engine governors and speed regulators for machinery.

2079. P. F. Cassegrain, Paris, gentleman. Improvements in firearms.

2081. Dr. W. Smith, Over Darwen, weaver. Certain improvements in power looms for weaving.

2085. W. Croits, New Lenton, near Nottingham, lace manufacturer. Improvements in the manufacture of fabrics by lace machinery, and in the means or apparatus employed therein.

2087. H. R. Summons, Navarino Terrace, Dalston Road. Improvements in machinery or apparatus for bordering envelopes, paper, and cards.

2089. G. Payne, Grantham, Lincolnshire, shoeing smith. Improvements in horse shoes.

2091. A. C. Vautier, Paris. Improvements in obtaining fibrous materials, and in manufacturing paper pulp, also in preparing, bleaching, and treating fibrous materials and fibrous and textile fabrics, and in producing agents used in part of the invention.

Dated July 25, 1862.

2116. W. Clark, 53 Chancery Lane, engineer. Improvements in rafts or structures applicable for the ordinary purposes of marine and inland navigation, as also for saving life in cases of shipwreck or otherwise. (A communication.)

Dated July 29, 1862.

2152. G. Waldie, Linlithgow, printer. Improvements in colour printing, and in the machinery or apparatus employed therein.

Dated July 30, 1862.

2162. W. Wanklyn, Albion Mills, Bury, cotton spinner. Improvements in apparatus for opening and conditioning East Indian and other tightly-compressed cottons.

Dated July 31, 1862.

2170. E. F. Prentiss, Birkenhead, chemist, and R. A. Robertson, Liverpool, brewers' and distillers' engineer. Improvements in obtaining products from rock oil, coal tar, and other like mineral substances, in a more or less pure and deodorised state, and in the apparatus to be used therefor, and which is also applicable to distillation in general.

2172. J. & E. Ransom, Kempston, Bedfordshire, millers. Improvements in mounting mill-stones.

Dated August 1, 1862.

2178. J. Sinclair, Glasgow, manufacturer. Improved arrangements for ventilating, and in part applicable for fumigating.

2180. G. Haseltine, 100 Fleet Street, American barrister at law. Improvements in apparatus for drying grain, gunpowder, and other granular substances. (A communication.)

2182. J. C. Onions, Birmingham, portable forge manufacturer. Improvements in portable forges.

2184. J. E. Marsh, Birmingham, rivet manufacturer. An improvement or improvements in metal rivets used in joining or securing together parts of boots, shoes, and other articles of leather, and also in machinery for making such rivets.

Dated August 2, 1862.

2188. T Onion, Calais, France, engineer. Improvements in rotary steam engines and in propellers adapted to propelling vessels in water.

2190 J. Gray, Glasgow. Improved arrangements for cleaning ships' bottoms, and for preventing the fouling thereof.

2192. C. Warne, Syleham Mills, near Scole, Norfolk. Improvements in the manufacture of linen drabbett.

Dated August 5, 1862.

2196. J. Thoma, Prussia, 35 Poland Street, Oxford Street. An improved self-adjusting screw wrench.

2202. A. Priestley, Huddersfield, machine broker. Improvements in arrangements or apparatus applicable to locomotive railway engines and carriages for distributing sand upon the rails to give adhesion to the driving and brake wheels of such engines and carriages.

Dated August 6, 1862.

2204. J. C. Richardson, Lichfield, manufacturer. An improvement or improvements in cleaning cotton waste.

2206. W. G. Valentin, Royal College of Chemistry, Oxford Street, chemist, and F. Levick, Blaina, Monmouth, ironmaster. Improvements in the generation of combustible gases for lighting and heating purposes, and in the mode of applying such gases to the manufacture of iron, glass, and other processes in the arts where great heat is required.

2208. J. H. Johnson, 47 Lincoln's Inn Fields, gentleman. Improvements in the construction of armour plates for ships and forts, and applicable to other like purposes. (A communication.)

Dated August 7, 1862.

2210. C. Culling, Downham Market, Norfolk, gunmaker. Improvements in firearms.

2214 R. A. Brooman, 166 Fleet Street, patent agent. Improvements in ships and vessels in order to prevent injury from collisions. (A communication.)

2216. W. Clark, 53 Chancery Lane, engineer. Improvements in the rig, spars, and sails of ships and other vessels. (A communication)

2218. R. W. Ralph, Honnington Grange, near Newport, gentleman. Certain improvements in, or applicable, to reaping machines.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

965. S. Fielding, S. Fielding, jun., R. Fielding, and T. Fielding. Valves.
971. M. Walker. Breech-loading rifles and other fire-arms.
972. W. Begg. Consuming smoke.
974. J. Colling. Reefing ships' sails.
975. A. Clark. Manufacture of revolving window shutters and blinds.
977. R. A. Kobitzsch. Diving apparatus.
980. C. S. Duncan. Apparatus for ventilating.
989. J. Carrington. Bricks.
997. F. W. Brearey. Medicated cups or vessels.
998. E. H. C. Monckton. Time keepers.
1004. J. Wright. Joining together armour and other thick metal plates, beams, and girders.
1005. T. Cobley and J. Wright. Treating auriferous and argentiferous minerals.
1007. J. E. H. Andrew. Looms for weaving.
1010. J. & J. Bullough. Looms for weaving.
1013. J. Jones. Constructing and arming ships and vessels.
1016. J. Knowelden. Steam, water, and other fluid engines.
1023. W. Nunn. Lanterns.
1024. J. Houghton. Haversack.
1031. J. Platt, W. Richardson, and W. Holland. Carding engines.
1032. J. Petrie. Apparatus for blowing and exhausting air.
1033. G. Burge. Protecting forts.
1034. C. Bartholomew and J. Heptinstall. Manufacture of tyres.
1043. W. E. Gedge. Lamp.
1047. T. Knowles, J. Houghton, W. Knowles, and W. Houghton. Looms.
1048. E. Butterworth. Applying adhesive substances to preserve the form of cops of yarn.
1051. J. H. Johnson. Fire-arms. (A communication.)
1058. E. Drewett. Bottles and other vessels.
1059. A. S. Campbell. Surface condensers.
1060. A. S. Campbell. Refrigeration of liquids.
1061. J. Park. Steam engines.
1062. E. Peyton and W. F. Batho. Angle iron.
1063. J. F. Spencer. Steam engines.
1069. J. K. Hampshire. Safety cage.
1075. R. A. Brooman. Pumps. (A communication.)
1076. R. A. Brooman. Hobby horse. (A communication.)
1077. C. J. Coxhead. Pianoforte actions.
1081. F. A. Le Mat and C. F. Girard. Fire-arms.
1082. R. Roche. Gun carriages.
1086. J. Platt and W. Cheetham. Looms.
1087. J. Platt and W. Richardson. Cleaning wool.
1088. R. A. Peacock. Constructing and working lock gates for docks, harbours, canals, and navigable rivers.
1091. F. C. Philippson. Steam hammers.
1098. W. F. Lock. An elongated projectile to be shot from smooth bored ordnance, and which shall retain, during its flight, the longer axis in the direction of its line of flight, similarly to elongated projectiles propelled from rifled ordnance.
1104. F. P. Warren. Steering sea-going vessels.
1105. M. Cartwright. Manufacture of models, and of plates or pieces for artificial teeth.
1110. J. H. Johnson. Machinery or apparatus for cutting the teeth of wheels, racks, or segments. (A communication.)
1122. J. Murphy. Looms.
1128. R. A. Brooman. Taps and valves. (A communication.)
1129. R. A. Brooman. Buffing apparatuses and draw springs. (A communication.)
1133. W. Clark. Railway rails. (A communication.)
1134. J. C. Rivett and J. M. Hetherington. Preparing cotton and other fibrous materials for spinning.
1135. R. Wedgwood. Apparatus for facilitating the saving of life in cases of fire.
1138. J. S. Phillips. Propulsion of vessels through the water.
1141. R. Stuart, G. Stuart, and H. Hill. Fastening flyers upon spindles.
1148. A. N. Wornum. Pianofortes.
1175. R. Jinks. Apparatus for suspending, raising, and lowering Venetian blinds.
1177. W. Moir. Ascertaining the specific gravity of liquids.
1179. G. H. Birkbeck. Lubricating apparatus. (A communication.)
1224. W. E. Newton. Chimneys for lamps. (A communication.)
1230. W. Clark. Collars, wristbands, and cuffs. (A communication.)
1235. G. Bischof. Treating solutions containing copper and silver.
1285. W. E. Newton. Lamps. (A communication.)
1294. T. F. Griffiths. Raising or shaping sheet iron.
1319. S. Merolla. Fire-arms.
1320. W. E. Newton. Joining boxes. (A communication.)
1349. W. & J. Richard. Manufacture of printing types, spaces, and quadrats.
1400. G. C. Haseler. Manufacture of lockets.
1521. W. Naylor. Forging metals.
1779. J. F. Allan. Improved furnace arrangements to prevent smoke and economise fuel.
1874. G. Peterson. Ascertaining the quantity and strength of spirits or other products obtained by the process of distillation. (A communication.)
2007. T. Hill. Protection of markers at rifle-butts, and in the means employed in indicating the score and position of the shot, and wiping out the shot mark.
2043. M. Kurts. Manufacture of handles for umbrellas, parasols, and walking sticks.
2067. W. Tranter. Fire-arms.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed August 15, 1862.

410. J. Cooke.
413. J. Chatterton and W. Smith.
415. A. H. Harrison.
419. H. Crawford, J. Crawford, R. Crawford and R. Templeton.
428. R. Watkins.
430. J. Lees.
434. W. Firth.
435. C. T. Marzetti and J. Watson.
436. J. T. and G. Pendlebury.
441. N. Symons.
443. W. Hinton.
444. W. Davis.
445. J. Paterson.
448. J. Willcox.
450. J. Friedlaender.
455. J. Paterson.
456. J. Paterson.
457. C. Wood.
459. J. Spence.
464. E. S. Crease.
465. R. & W. E. Pickin.
467. W. M'Adam and W. Chrystal.
469. H. Chavasse, T. Morris, and G. B. Haines.
479. D. B. White.
483. W. B. Johnson.
505. W. Clark.
525. W. Miller.
527. W. Clark.
547. J. C. Ratliff.
585. J. Gjers.
601. E. Partington.
643. W. J. Bennet.
751. T. Dunn.
1182. A. Robertson and R. Barter.
1473. C. Attwood.
1651. W. E. Newton.
1653. W. E. Newton.
1798. J. H. Johnson.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

1867. D. Campbell.
1936. T. Briggs.
1939. H. Smith and T. W. Ashby.
1991. J. Chatterton.
2341. F. Levick.
1946. J. M. Hetherington.
1972. G. Collier.
1903. W. Wilson.
1941. A. P. Chamberlain.
2065. H. O. Robinson.
1893. H. Medlock.
1908. J. Fowler, R. Burton, D. Greig, E. E. Allen, and W. Worby.

PATENTS ON WHICH THE SEVENTH YEAR'S STAMP DUTY HAS BEEN PAID.

1747. A. Allan.
1871. G. Collier.
2058. J. C. G. Kennedy.
1841. G. Sanders and R. E. Donovan.
1848. S. Statham and W. Smith.
1867. W. E. Baker.

THE

MECHANICS' MAGAZINE.

LONDON, FRIDAY, AUGUST 29, 1862.

THE INTERNATIONAL EXHIBITION.

Iron and Hardware.

In our various notices of the contents of the International Exhibition, we have endeavoured to do something like justice to those manufacturers and others who have contributed the products of their inventive skill and practical talent, and especially to those who have excelled in the mechanical arts and furnished the best illustrations of applied science. It is impossible, however, for us to traverse the nave, transepts, courts, galleries, and annexes of the spacious but ungainly building, without becoming painfully conscious of the gigantic nature of the task, and of the certainty, after all, of leaving some points of interest untouched. Merely general remarks upon the innumerable items which everywhere present themselves to the eye, and plead eloquently for individual comment, seem but an inadequate return for the extraordinary ability of which those items are the witnesses; and yet particular notice of all is simply an impossibility. To those exhibitors who may feel that at our hands they have not, as yet, received their fair meed of commendation, we can only plead the enormous difficulty of the work, and ask them to have patience.

In the Eastern Transept we are aware that there are materials for articles which would fill our columns, and fill them advantageously to our readers, for many months to come. Unfortunately, however, we are only able at present to deal with some of the most important of those materials. Messrs. Naylor & Vickers, of Sheffield, here exhibit an admirably arranged display—trophy is, somehow, not a palatable word — of the works for which they are celebrated. When we say "admirably" arranged, we speak advisedly, and the adjective is justified by the fact that each specimen of workmanship exhibited by them is so placed that it may be fairly seen and properly examined. Railway wheels, and tyres of cast steel, form the most conspicuous features of the show, and these are exhibited in their several stages of progress from the sand to the finished article. The severe strains to which they have been subjected, with a view to demonstrate the quality of the substance of which they are composed, are obviously apparent; and it is impossible for the practical man, after examining into the results of those testings, to gainsay the evidence of excellence which they adduce. The disc wheels for locomotives appear especially adapted for the purpose for which they are designed; and testimonials from the several railway companies by whom they have been successfully used, are a proof that they not only appear but actually are so. To our thinking, their form is such as to combine lightness and strength—those important desiderata in almost all kinds of machinery, and peculiarly so in locomotive engines.

In cast-steel axles, Messrs. Naylor & Vickers are well represented in the Eastern Transept. These are shown in the rough, after turning, and when bent by the irresistible force of hydraulic pressure. Piston rods are to be found of various sizes, and in one case a locomotive piston and rod in one solid piece. This is an excellent specimen of workmanship; and, with the cast-steel double-crank axles exhibited, is a remarkable proof of the capabilities of the firm to produce elaborate as well as simple articles of the beautiful material, in the treatment of which they excel.

To enumerate the variety of specimens of workmanship in relation to railway economy, would exceed the limits of space at our command; but it would be unfair to omit honourable mention of Messrs. Naylor & Vickers' solid cast-steel reversible railway points or bearings. The name of these conveys a correct idea of the purpose for which they are intended, and it needs but one glance from the eye of a railway engineer to discover their adaptability to that purpose.

Wheels and pinions of cast steel are shown in the rough and after trimming, and they promise to inaugurate a new era in mill-work. Boiler-plates of the same substance, for locomotive and marine engines, and capable, although of extreme lightness, of withstanding high pressures, are to be seen in the display under notice. So far we have confined our observations in reference to the stand of Messrs. Naylor & Vickers to those specimens of their handicraft which relate to the arts of peace. Like many other engineers and manufacturers during the last few years, however, they have been obliged to turn their attention to the formation of implements of destruction; and their exhibition of ordnance of varied kinds and calibre, finished and unfinished, will well repay the inspection of those who desire to be convinced of the universality of application of cast steel. The density and homogeneity of the metal used in the construction of the guns exhibited, promise to offer the maximum of resistance with the minimum of weight. We have no reason to doubt that the samples shown are fairly selected ones; and, if they are so, we must congratulate the firm on the success they have achieved in the direction of ordnance manufacture.

The cast-steel bells of Messrs. Naylor, Vickers, & Co., are so well known, that it becomes a superfluous task to do more than mention them here. All who have gone into the Exhibition must have observed those which grace the Eastern Transept, or have heard their clear and silvery sounds. During the last five years, we are told, no less than three thousand steel bells, varying in size from 7ft. 6in. in diameter down to 12in., have been purchased from the Sheffield works. They have the advantage over bronze bells of costing 40 per cent. less per lb.; and as they are made of far less thickness in proportion to their diameter than bronze, it is easy to comprehend the economy, in all respects, derivable from their use. Large as has been the demand for steel bells, it is probable that the publicity given them in the Exhibition will greatly extend that demand.

Speaking of bells, we turn now to a set also arranged in the Eastern Transept, but of a different material to that employed in the manufacture of those to which we have just referred. These are of bronze, and the work of Messrs. Warner & Sons, of the Crescent, Jewin Street, London; and certainly they loudly and musically testify to the skill of the manufacturers. They are so arranged as that it does not require a knowledge of music in the chimer to make them chime melodiously. A perforated barrel placed beneath the set of bells, and mechanically driven, causes their tongues to move in harmonious unison, and to draw forth the most dulcet sounds. (We gave an illustrated description of this peal of bells in a recent number of the Magazine.) The firm in question, as is well known, have for several years past devoted great attention to the art of bell founding, and recently they have patented a process in connection therewith which has been productive of the best results. The large bell for the Clock Tower of the New Palace at Westminster, and which elicited so much discussion in and out of Parliament, was the work of Messrs. Warner & Sons. It is, indeed, the largest bell in England, and it may not be improper here to give its dimensions, which are as follow:—

	ft.	in.
Diameter at mouth	9	$5\frac{1}{2}$
Height	7	$10\frac{1}{2}$
Thickness of sound bow		$9\frac{5}{8}$

Weight with clapper, 16 tons, 11 cwts., 2 qrs., 20 lbs.

The means and appliances which Messrs. Warner & Sons have at their disposal for the casting of bells may be judged of by the Brobdignagian proportions of the Parliamentary bell. Between this monster and the smallest hand-bell for domestic purposes, the firm named are able to produce every intermediate size. It is not for bells alone that the Messrs. Warner are remarkable in the International Exhibition: their pump "trophy," in Class 8, gives an excellent notion of their performances in respect to hydraulic machinery. It is not too much to say, indeed, that in pumping apparatus they are almost unrivalled. From the most powerful machinery employed in raising and forcing water, down to the smallest hand pump or garden engine, they are equally at home. Were we to attempt to particularise the variety of hydraulic machines which owe their origin to the Messrs. Warner, we should probably trespass as much on the patience of the reader as on our own space. For fire-engines they have made for themselves a name which, when the arrangements for the suppression of fires in the metropolis, which the Government have it in contemplation to make, are completed, will be a great and legitimate recommendation to them. In various parts of the International Exhibition, indeed, Warner's fire engines are to be found. In Class 31 the same firm shine conspicuously in respect of braziery, baths, steam fittings, &c.; whilst for horticultural implements, Class 9 (Taylor's Conservatory) tells a flattering tale of the Messrs. Warner & Sons. For the last-named, indeed, they have received "Honourable Mention" from the jurors, the highest award made in the horticultural branch of the World's great Show. For their chiming machinery, apart from that attached to the bells named, and to be seen in Class 31, Messrs. Warner also have gained a prize medal.

If our notice of this firm be scarcely commensurate in length or fullness with the extensive display they make at Kensington, the fact must be attributed to its true cause—the pressure of other matter upon our columns.

Next week we shall pursue our enquiries in respect to iron and hardware.

AUSTRALIA AT HOME AND AT THE INTERNATIONAL EXHIBITION.

Although many desultory articles have appeared in the public prints of the day, in relation to what may be termed the Australian Section of the International Exhibition, yet it seems to us that but a scant measure of justice has, upon the whole, been dealt out to it. It is this consideration, and the desire we have to communicate to our readers matters of interest and importance, come from whence they may, that induce us to endeavour to repair the shortcomings of the press in its treatment of Australia, and Australian productions. The task is rendered the more easy from the fact that the able Secretary to the Victoria

Commissioners, J. G. Knight, Esq., has furnished us with some admirably-arranged statistical, and other information in relation to the great colony in question. The actual amount of space accorded to, and occupied by, the various divisions of the Australian continent in the Exhibition, is as follows:—

	Superficial feet
Victoria, in four allotments	5,665
New South Wales	2,500
South Australia	1,800
Queensland	1,462
Western Australia	625
Tasmania	1,600
	13,652

We include Tasmania in this table because it is so near a neighbour of the Australias that it would be unfair to treat it as a distinct colony. It will thus be seen that, so far as the floor area occupied by our friends at the Antipodes is concerned, they are fairly accommodated. The awards of medals and of "honourable mention" by the jurors to Australian Exhibitors is in consonance with the space they occupy, and, although we may rest assured that the echoes of bickerings, and of grumblings from the lips of the disappointed, will by-and-by reach us, yet there is little real ground for them. The decisions of the jurors in reference to the provinces named above are in this wise:—

	Medals	Honourable mention
Victoria	111	92
New South Wales	76	50
South Australia	25	18
Queensland	26	20
Western Australia	15	12
Tasmania	38	26
Total	291	218

We need not particularise the objects which the jurors have especially selected for distinction, and, indeed, the space which such a mode of proceeding would demand is a barrier to its being carried out. It may be stated that in both the mineralogical and agricultural departments, the Australian awards have been extensively made, and we infer therefrom that the colonists are not, as some have imagined, so completely absorbed in the pursuit of the wealth which lies below the surface of the earth, as to lose sight of the means of making the surface itself productive.

In the useful and ornamental arts, too, it need not be said that Australia has distinguished itself in the Exhibition, because a visit to the courts of the South Kensington palace will demonstrate the fact most fully. The province of Victoria, in its display of machinery, instruments, implements, and tools, has made itself remarkable in the highest degree, but the unprecedentedly rapid progress of that colony is sufficient, perhaps, to account for the excellence it has attained in these directions. It is questionable whether any parallel in ancient or modern times can be found to the speed with which Victoria has advanced on the high road of civilisation, or developed its material forces. In the year 1836, the census of Port Phillip, since re-christened Victoria, gave the following returns:—Males 142, females 35; total 177. At that time and up to the year 1851, Port Phillip was a province of New South Wales. In 1851, Victoria was separated from the Government of New South Wales, and started as an independent colony, with 77,345 inhabitants. The population of the adjoining and parent colony was at that time 197,168 persons, or 119,823 more than that of Victoria. Since the year 1851, however, the increase of population in the last-named place has been positively astounding, for the census of the Australias in 1861 gave the subjoined return:—

Victoria	540,322
New South Wales	350,860
South Australia	128,000
Queensland	30,051
Western Australia	16,000
Tasmania	89,977
	1,155,210

As may be imagined, the march of improvement has kept pace with that of the population, and from the mass of statistical materials with which Mr. Knight has supplied us, we extract some items, which eloquently prove that this is so. Under the heading of "Public Improvements," we find that since the year 1851, the under-mentioned sums have been expended in the colony of Victoria:—

	£
Public Works, exclusive of Railways	4,211,753
Public Roads and Bridges	5,272,620
Government Railways to Geelong, Ballarat, and the River Murray, in all 219 miles	828,233
Suburban Railways undertaken by private companies	1,154,505
Electric Telegraphs, 1,504 miles	163,000

Figures like these speak more convincingly of prosperity and advancement than whole columns of writing could possibly do. No doubt the mineral products of the colony are in all respects at the *base* of this extraordinary onflow of progress, and they really account for it. The quantity of gold exported from Victoria between October 1, 1851, and October 1, 1861, amounted to 26,163,432 ounces troy, equal to 800 tons 17cwt. 3qrs. 7lbs., or in value, 104,649,728*l.* sterling. The pyramid which stands beneath the Eastern Dome of the International Exhibition, and attracts the notice of all who enter the building at that point, was designed by Mr. Knight to show the comparatively small space which, from its density, so large a quantity of gold would occupy. The actual measurement of the figure is only 1,492¼ cubic feet, yet the value it represents is equal to one-eighth of the national debt of Great Britain.

It may be stated, that since the pyramid was designed, and up to the last accounts, the gold fields of Victoria have yielded a further quantity of 35 tons 2 qrs. 6 lbs., the value of which is 4,642,238*l.* Models of the principal "nuggets," or lumps of gold, found in the colony, are shown in low relief on the base of the pyramid. The exact height of the structure is 44 feet 9¼ inches, and it is 10 feet square at the base.

We have been thus particular in reference to the colony of Victoria and its productions, because it is well that those who go to the Exhibition should have their minds stored with such facts. They are thus in a better condition to appreciate what they see, and to account for its existence. In future remarks which we shall have to make upon the Australian divisions of the International Exhibition, we shall endeavour to do justice to the other great colonies, which are no insignificant competitors with that upon which we have now more especially dwelt. The area of Victoria is 86,831 square miles, or 55,571,840 acres, which is about the same as that of England, Scotland, and Wales united. The number of periodical publications printed and circulating there is 100, and specimen copies of nearly all are to be found in the Exhibition. In Melbourne alone there are published, of newspapers and magazines, three daily, thirty-three weekly, ten fortnightly, ten monthly, one quarterly, and one yearly. A striking proof of the extraordinary progress of Victoria is given in the following extract from a volume published at Ballarat:—"When the Great "Exhibition of 1851 was opened, the only "habitation on the site of the present town of "Ballarat was a shepherd's hut, built of slabs "of wood, and roofed with bark. In a circle, "having Ballarat as a centre, with a radius of "forty miles, the population then did not exceed 500 persons, and consisted of a few "sheep-farmers and their dependants. The "population of the same area when taken "in 1861 was 105,996 persons. At the present time, there are published in Ballarat "four bi-weekly, one weekly, and two daily "papers." Such is the gourd-like growth of Australian provinces and towns. The interior explorations of Australia will presently lead to a wide extension of that growth and developement, and who shall say when it will reach maturity?

CRINOLINE.

Although the title of this article may startle somewhat the readers of the Mechanics' Magazine, yet is there much in relation to the material which is of interest to them. For several years past many hundreds of workmen have been employed in its production, and every week hundreds of miles of crinoline are manufactured in Sheffield. The demand for the article appears, indeed, to increase rather than diminish, and wherever civilisation exerts its influence, the fashion of wearing it has extended. It is not alone, however, in the direct conversion of iron into the narrow ribands of steel which constitute crinoline, that an impetus has been given to trade. The brass and iron wire makers and workers of the kingdom have derived largely-increased employment through the predominance of the fashionable weakness. The quantity of wire used in the manufacture of fire-guards for the prevention of those accidents from the use of crinoline, which, nevertheless, are of too frequent occurrence, is immense. In fact, we believe that the weight of iron and brass consumed in the making of fire-guards is far greater than the weight of crinoline, which Sheffield and other seats of its manufacture produce. Of course a corresponding amount of activity has resulted to the makers of wire-drawing machinery, and of rolls and other apparatus for the manufacture of crinoline. We say nothing of the effect that both branches of trade have had upon ironmasters, and agents connected with them, because it is palpable that that effect must have been most beneficially felt. Who shall say, then, that crinoline is too trivial a subject to be entertained in the Mechanics' Magazine?

It is not our province, we admit, to discuss the wisdom of wearing the gossamer-like and expansive material, although, in our professional visits to the International Exhibition on crowded days, the question has pressed itself upon us with considerable force. There is, nevertheless, a point of view from which we may legitimately look at crinoline; and it is that of its influence as an industrial product upon the well-being of our artizans and work-people generally. It is to the Empress Eugenie, of France, that the classes of manufacturers and their employés to whom allusion has been made, are indebted for their new and extensive occupation. That illustrious lady appears, indeed, to be as potent in the realms of Fashion as was Diana of the Ephesians; and she has the advantage over that ancient potentate of having the command of inexhaustible scientific appliances for the realisation of her edicts. The taste of the Empress is the oracle, and her boudoir the

temple, whence issue laws which, unlike those stupid ones of the Medes and Persians, are perpetually undergoing mutation. Great as is the power of her Imperial husband, hers is a still wider dominion—he only rules France, while she holds in leading-strings of mauve or magenta dye the entire female world! He is said to have imposed fetters on his subjects, but she envelopes hers in hoops of steel. Napoleon exhibits his autocratic will in reference to shades of opinion; that of the lady is as arbitrary and potent over the hues of ribbon. We dare say that the extraordinary prevalence of a particular fashion was never more widely illustrated, in every sense, than in the current wearing of crinoline. It has outrun the march of the missionaries. Even the female members of the wild Caffre tribes have been bitten by the passion for a circumference of skirts; and in their case, perhaps, the innovation may be regarded as an improvement. Where the alternative lies between no skirt at all, and too much of it, we cannot hesitate in giving a decided preference to the latter extreme.

Still, when this overbearing Parisian mode shall come to be adopted in the region of the Hottentots, it will not be deniable that the fashion has reached its climax of superfluity. We venture to believe that an "idea" and obedience to it were never more rapidly extended over the globe. The idea of diffusing the female dress is now shown to be the truly diffusive one, and hence workers of iron and steel occupy the strange position of supplementing the exertions of the milliner.

The ladies are imitative beings, and when the Empress first diminished her bonnet, and then moved it off her head altogether, they, one and many, did so too. What she did in the matter of petticoats was immediately adopted wherever that garment, which Byron reverently called "a mystical sublimity," was worn or obtainable. What the next movement of the fair monarch of the world of Fashion may be we know not, but it is certain that it cannot be more universally copied than has been that of wearing crinoline.

A RETROSPECT OF ENGINEERING AND ARCHITECTURE.*

These are the days of steam and electricity. The post is too slow for us, and the stopping train is voted a bore. We live in a perpetual whirl. Onward is the watchword. Now the wisdom of all this is very questionable. *Festina lente.* It is not the "crib" at school or the "cram" at college that makes scholars. The hurried meal impairs digestion and defeats the very end for which it is taken. The man who makes every journey at express speed is not necessarily a great traveller—that is measuring a traveller by what he sees and what he is able to describe. It may be more convenient to be whirled to York in four hours, but the old traveller who took six times as long to perform the distance could give a far more interesting account of the journey—its hills and valleys, its rivers and streams, it woods and meadows, its fens and moors, the quaint old inns, the stately mansions, the deserted ruins; how, as he rambled along, milestone after milestone was carefully noted—how, when the hill was climbed and the horses were taking wind on the summit, the eye wandered over the delightful prospect, the valley behind, the vast plain stretching out before—how town after town and village after village were entered and passed, marking at each succeeding stage the progress towards the journey's end.

It is just in this way that certain annual publications mark the progress of the age in literature, in science, and in art, and such books, when compiled by men who are authorities on the subjects of which they treat, are not only welcome but peculiarly valuable. We are glad, therefore, to find so learned and scientific an authority as Mr. Burnell, recording for the benefit of readers, both professional and non-professional, such an amount of information as he has brought together in the first volume of the "Annual Retrospect of Engineering and "Architecture." The range of subjects is extended, embracing in five divisions almost everything of importance that was either a matter of speculation or became a recognised fact in the engineering and architectural world during the past year. Thus we are treated to articles on Metropolitan Railways and Streets, Street Tramways, Railway Accidents, the Broad and Narrow Gauge Question, the Thames Embankment, the Waters of the London Docks, Steam on Canals, Petroleum Oils, the Mont Cenis Tunnel, a comparison between the Street Architecture of London and Paris, the Preservation of Stone, Coast Defences, the Fleet of the Future, Coles's Cupola Ships, the Strength of Iron Ships. Be it remembered this is by no means a complete list of the subjects treated of in this volume, and it is only just to the editor to say that his articles are not mere compilations or dry records, but are entirely recast in the mould of his own well-stored mind, and exhibit a depth of thought and an originality of treatment not often to be met with in books of much loftier pretensions than a "retrospect" can possibly make.

On the subject of railway accidents, Mr. Burnell writes: "In the winter of 1860-1 many "accidents occurred on the English railways, "*from the great changes produced in the mole-*" *cular structure of the iron used in the working*" *parts of the engines and carriages, especially*" *in the tyres, axles, connecting rods in the rails,*" *chains, points, and crossings,*" &c. Now our author assumes here, what will be seen from our review of Mr. Kirkaldy's work on experiments in wrought iron and steel, is still an open question, the only proof, or rather assumption of proof, that the "molecular struc-"ture" of the iron becomes changed in use, is in the fact that the fracture is crystalline, whereas the iron is, or should be, fibrous; but this crystalline appearance Mr. Kirkaldy's experiment clearly shows is due, not to the molecular structure, but the *suddenness* of the fracture, which is especially the case in railway accidents. Our author's suggestion of a possibly efficient remedy for railway accidents is, we think, worthy of close attention. "A passenger," he says, "who takes a seat in a railway carriage, "becomes at once a helpless being, at the mercy "of an engine-driver and stoker, of some guards "and watchmen, all of whom are usually "ignorant, uneducated men, utterly unfit to be "intrusted with the fearful power over the "lives and limbs of the hundreds committed "to their charge. It may be laid down as a "law, that no unforeseen accident can happen "to the roadway and rolling stock, if proper "attention be paid to it. On a well-managed "line of railroad, no collisions, no runnings "of one train into another, could occur. The "questions really to be solved for the pre-"vention of railway accidents are, how to "organise the most efficient superintendence "of the road and of the plant, and how to insure "the regularity of the arrivals and departures "of the trains, so as to avoid collisions? From "practical experience of railway working, and "from long and anxious consideration of all "the circumstances connected with it, we are "sure that one of the most efficient solutions "of the question is to be found in the concen-"tration of the administrative power of those "establishments in the hands of one person, "and in rendering him personally and pecu-"niarily responsible for the neglect of duty "by his subordinates, selected by himself, and "acting exclusively under his orders."

It appears from Mr. Burnell there is still hope for canal property. We had almost thought the canal system was drowned, beyond the resuscitative powers of all the Humane Society staff. It appears, however, after all, only to be a case of suspended animation. Rectify and improve the water-courses themselves, and then, as our ingenious neighbours across the Channel borrowed the idea of a canal steam-system from Mr. Rendels' ferry boats over the Hamoaze and the Itchen, let us take a trip to Paris, stroll along the banks of the Seine as far as Rouen, and observe on our route the very curious plan of steam traction in operation. Mr. Burnell says:—"Perhaps the most striking application of "steam power to water transport is the one "lately made upon the Seine, in both its "upper and lower reaches, and now in course "of application to some of the artificial lines "of water-communication of France. In this "case the first step was to establish between "Paris and Rouen, following all the windings "and the locks of the Seine, a strong chain "cable lying loose upon the axis of the na-"vigable channel. Steam tug-boats are pro-"vided, carrying engines of 150 or 200 horse-"power, working at high pressure, upon "the same principle as the locomotive engine. "The boats bear fore and aft guide pulleys, "susceptible of being moved by the same "machinery as the rudder, which take up the "slack of the cable and lead it to a drum wheel, "round which it passes a sufficient number of "times to produce an efficient resistance to "the action of the engine, and thus to propel "the boat without either wheels or screw "working on the water. The barges to be "towed follow at a small distance behind, or "they are occasionally lashed to the sides of "the steam-tugs, and in this manner trains of "6, 8, or 10 barges of 240 tons each descend "the Seine at the rate of six miles per hour, "or remount it at the rate of four miles an "hour, at prices per haulage considerably "lower than those formerly paid for horse "traction. It is something of this description "which is required for our artificial canals, "modified, no doubt, for the passage of small "tunnels, unfit to receive engines blowing off "large volumes of steam and smoke, and for "the canals having soft muddy bottoms; but "as the cost of establishing such a system "must be considerably less in England than "in France, it would be very desirable to "attempt its application here."

It was said of Augustus that he found Rome of brick, and left it of marble. Perhaps Napoleon III., who has avowedly made the first Cæsar his study, is also ambitious to vie with the second and greatest of all the Cæsars. Certain it is, that if a proscribed legitimist, who had not visited the capital since the fall of the Bourbon, or an Orleanist refugee who may have accompanied Louis Philippe in his flight in 1848 and had not since returned, were now to visit Paris, he would find it indeed changed. Whatever the motive, whether policy, or vanity or philanthropy, the present Emperor has endeavoured to make his capital not only the gayest

* The Annual Retrospect of Engineering and Architecture: a Record of Progress in the Sciences of Civil, Military, and Naval Construction. Vol. I. By George R. Burnell, C.E., F.G.S., F.S.A. Lockwood & Co., 1862.

but the grandest in Europe. This has been done at an enormous cost; for, according to M. F. de Lasteyrie, quoted by the author of the Retrospect, "the indemnities paid or to "be paid by the city of Paris for the expro- "priation of the houses recently demolished, "has amounted to the enormous sum of "12,840,000*l*. since 1852, and the amount was "still far from being closed." Now, what is the effect of all this? Why, our author tells us that, whilst much requires to be done to render London as convenient as it might be made, it nevertheless contrasts favourably with Paris. "There is," he says, "perhaps a want "of unity of direction, and of grandeur of "conception, in the works of improvement "lately executed in London; but a careful "comparison of those built here for domestic "purposes with those erected in Paris will "prove that the rule of tempered liberty is "far more favourable for art than is the most "perfect system of governmental organisa- "tion. There is greater vigour, more thought, "originality, and truth in the buildings lately "erected in Cannon Street, Fenchurch Street, "Cornhill, Leadenhall Street, than can be "found in any new part of Paris; and even "the builders' architecture of South Kensing- "ton and of Tyburnia, detestable though it "be, is bolder, freer, and of a purer taste than "the meretricious architecture of the new "Boulevards of Paris." Our author complains that "the houses in the new streets of "the French metropolis are drilled to the "same degree of uniformity as a regiment of "soldiers would be; whilst all originality, all "the quaint picturesqueness of outline which "was observable in old Paris, have disappeared "under the influence of the modern notion of "equality. The long vistas of the streets, "stretching away until their sides almost "seem to meet at the vanishing point, singu- "larly contribute to this effect of monotony; "and as the new streets have no historical "recollections connected with them, they are "in every respect dull, stale, flat, and unpro- "fitable. The taste of the architectural de- "tails in the elevations is also as questionable "as their general effect; for the 'bed-post "and valance' style of ornamentation, the "unmeaning introduction of shallow paneling, "and the ineffective profiling of the mouldings "in accordance with the taste brought into "vogue by M. Duban, of the Ecole des Beaux "Arts, have been exaggerated in the new "streets." In another article elaborately written on the water supply of Paris, London stands in more than favourable contrast. Parisians may turn up their nose at our dirty Thames, and talk of their pellucid Seine; but what becomes of the daily accumulation of filth in a city containing a million and a half of people, to whom a daily supply of four gallons of water per head is accounted liberal, and by whom so much is not consumed? It will be a blessing for London when its noble river is freed from its pollution; but we should not like its waters rendered limpid at the expense of our three millions being compelled to live à la mode Parisienne.

We commend Mr. Burnell's book to the careful perusal of all interested in the subjects of which it treats; and although, to use a favourite word of the author's, it is to some extent an "anachronism," its articles have a more than temporary interest; and, as an amend for the delay in the appearance of this first volume of the "Retrospect," we are promised that each succeeding volume shall be brought out as early as possible, after the close of the year to which it refers.

EXPERIMENTS ON WROUGHT IRON AND STEEL.*

The work before us is a most important contribution to the literature of science, and should find a place among the works for every-day consultation in the libraries of all scientific men, and particularly, of all in the least degree connected with the manufacture or employment of wrought iron and steel. To quote from the title-page, it shows the results of an experimental enquiry into the comparative tensile strength, and other properties of various kinds of wrought iron and steel. The writer and experimenter is an authority on the subject, and his experiments, extending over a period of nearly three years and a half, appear to have been made with the utmost care and with a simple desire to elicit truth.

In the eighth section of the work the author shows, by numerous quotations, the unsatisfactory character of the knowledge possessed of the tensile strength of wrought iron and steel prior to his experiments. Among others, the following from a paper by Mr. S. Hughes, which appeared in a scientific paper in 1858, will show the necessity for the enquiries which the author has so patiently and perseveringly conducted. "There is, probably, no "branch of experimental enquiry in which "more varying and discordant results have "been attained than in that which seeks to "determine the absolute strength of wrought "iron subjected to a tensile strain, or to the "action of a weight applied to tear it "asunder.

"Writers on the strength of materials in "the last century seldom assigned to bar iron "a less tensile strength than thirty tons per "square inch as the weight which would tear "asunder a bar of ordinary wrought iron one "inch square. Thus Emerson gives the ten- "sile strength of bar iron at 34 tons, Selford "29·29, Drewry 27 tons; while at the present "day Templeton gives 25 tons, Beardmore "26·8, Brown 25, and Eaton Hodgkin- "son, probably from more careful experi- "ments than any other, 23·817. The iron "manufacture of this country has attained an "enormous development, which, unfortu- "nately, has not been accompanied by a cor- "responding increase of quality. On the "contrary, all the earlier experiments on iron "found a greater strength than is now pos- "sessed even by the best qualities. It is "foreign to the purpose of this article to give "the causes of this falling-off and deterio- "ration of a national manufacture, otherwise "it would be very easy to show a case of "serious national importance, which is, per- "haps, more worthy of the attention of our "legislators than those to which their labours "are commonly applied. Whatever be the "causes — whether the spirit of speculation, "the race of competition between the great "iron manufacturers to produce their iron at the "cheapest rate, or the introduction of new and "cunning chemical secrets to enable them to "work up inferior iron—certain it is that "our manufacture of wrought iron has been "seriously deteriorating during the last half "century; and unless some improvement "shortly take place, we shall, before long, "acquire a reputation for manufacturing only "inferior iron."

Shortly after the publication of Mr. Hughes's statements, our author's experiments commenced, and, after a protracted and laboured investigation, he comes to the conclusion that there "is not any satisfactory evidence to "show that the iron now produced is inferior "to that made during the last century."

One very important feature in the experiments made by Mr. Kirkaldy is, that he has not only noted down the ultimate strength or breaking weight per square inch of the original area of each specimen, but "the *contraction* "of the area when subjected to considerable "strain, and the still greater contraction at "the point of rupture which takes place in a "greater or less degree as the material is soft "or hard, and the consequent influence this "reduction must have on the amount of weight "sustained by the specimen before breaking. "The apparent mystery of a very inferior "description of iron suspending, under a steady "load, fully a third more than a very superior "kind, vanishes at once when we find that the "former had the benefit of retaining to the "last its original area only slightly decreased; "whilst the latter, on breaking, was reduced "to very nearly a fourth of its original area— "the one a hard and brittle iron, liable to "snap suddenly under a jerk or blow, the "other very soft and tough, impossible to "break otherwise than by tearing slowly "asunder."

Up to the period of making these experiments, it was deemed sufficient simply to ascertain and compare the breaking strains of various kinds of iron: hence, in the official enquiry into the loss of the "Royal Charter," the five plates recovered from the wreck were pronounced good, simply because, upon being tested, their mean breaking strain was 20·55 tons (46,032 lbs.) per square inch, instead of 19·56 tons (43·814), the average for Staffordshire plates. This obviously could afford no proof of the quality of the iron for shipbuilding purposes, as the high breaking strain might have been due to great hardness and brittleness, which would refuse to bend or twist, but snap at once under circumstances in which other iron would not have broken.

The material operated upon was rolled iron, hammered iron, and steel. With respect to rolled iron, the following conclusions have been arrived at:—1. That the quality of the iron improved as the diameter of the bar became less, but that this improvement was most marked in the inferior kinds. 2. That the generally received opinion, that the removal of the "skin" greatly reduced the relative strength, or that a *rough* bar is much stronger than one *turned* to the same diameter, is erroneous. 3. That *forging* affects the comparative strength of iron by rendering it harder, as evidenced by the diminished contracting power of the area. Referring to hammered iron, the author, after freely quoting from Mr. Clay, of the Mersey Iron and Steel Works, whom he pronounces to be "the highest "authority on the subject of forging large "masses," calls attention "to the important "difference between the 'scrap iron' used at "the forge in the formation of large masses, "and that designated 'best scrap' by the "iron master, as he believes that the "difference of opinion regarding scrap "iron is due, in a great measure, to the "want of this distinction. The former is "made up of old miscellaneous pieces collected "from every quarter, the latter composed of "new iron made in the same works, cut up "and worked over again; consequently, the "heterogeneous character of the one is totally "unlike the homogeneousness of the other." This, the writer contends, is a distinction that has been hitherto overlooked, and doubtless the records of his experiments upon specimens of both kinds of scrap, and the beautifully executed drawings of the fractures presented by each kind,

* Experiments on Wrought Iron and Steel. By David Kirkaldy. Bell & Bain, Glasgow. 1862.

will be closely studied by all interested in the forging of large masses. Of the necessity for including steel in the experiments, the author furnishes ample proof, and successfully combats objections made to his tabulated results. The author is certainly correct when he says "he has always considered that (steel) the "best only which best answers its particular "purpose;" and surely a knowledge of the tensile power of steel must aid the consumer in the choice of that which is best suited to his branch of manufacture.

Sections 10 and 11, on the appearance of fracture in Iron and Steel, will be read with great interest. They contain a summary of the long and important discussion, as to whether fibrous iron becomes changed to crystalline during its use. Our author shows clearly that in all sudden breakages the fractures must necessarily present a crystalline and not a fibrous appearance. He does not say that some of the causes assigned for the change from a fibrous to a crystalline condition may not have operated prejudicially on the *tenacity* or *cohesion* of the iron, and so facilitated the rupture, but that the appearance produced by the sudden rupture is no proof that a molecular change during use has taken place from the fibrous to the crystalline condition. The value of a work like the one before us depends upon several conditions. It is important that the author shall bring to his task a due amount of ability—that he shall be *practically qualified* for his work — that his experiments shall be made with the honest determination of arriving at the truth without fear of offending existing prejudices or coming into collision with supposed vested interests—that the subjects of his experiments shall be sufficiently numerous, and the results corroborated by repeated trials—that the tests themselves shall be simple and familiarly described, so that the qualities of the tests may if needful be tested, and the results verified. Now we believe the author has fulfilled all these conditions. He was many years practically employed by the well-known and highly-respected firm of Messrs. Napier & Sons, the eminent engineers, and, to use his own words, has endeavoured, "throughout "the whole of this investigation, to pursue it "with candour and impartiality, and to present "to those interested in such matters a plain "statement of the facts elicited." "I have," he says, "striven to avoid drawing anything like "unjustifiable inferences or deductions, and have "confined myself strictly to such conclusions "as I believe to be fully warranted by the ex-"periments. The data on which these are "based being all minutely stated, it will be in "the power of everyone to judge for himself "of their correctness." Of the variety of specimens the tables will themselves speak, and the mode of their collection was unexceptionable; the testing apparatus is simple, is fully described and illustrated; and we cordially commend the work as a valuable acquisition to one of the most important, if not *the* most important, of English manufactures.

THEORETICAL FORMULÆ FOR THE MOVEMENT OF AIR IN CONDUIT-PIPES.

By Gen. A. Morin,

Academy of Sciences of Paris.*

In the work upon the Steam Engine which I had the honour to present to the Academy of Sciences in 1843, I had, among other questions, treated of the movement of steam from its issuing from the boiler until its entry into the cylinder. The application of the principle of living-forces and of the rules admitted to estimate the influence of the various circumstances which the circulation of this fluid presents, to a steam engine established in the shops of the *Messageries Royale*, had, moreover, shown me that the results of experiment were as conformable to those of theory as one could hope for in such investigations.

As I have been induced for some time past to occupy myself with questions which are connected with the movement of elastic fluids, and especially with that of air in ventilation apparatus, I thought that whilst it was indispensable to consult experiment, it was also necessary to ask of Science, rules which might guide us in the establishment of the apparatus. I was thus led to seek for the means of establishing the formulæ for the movement of air, applying to it the principle of living-forces or of the transmission of work, according to the rules indicated by Borda, and developed by M. Poncelet in his lectures at the School at Metz.

In this work, of which I propose to give to the Acadamy an analysis as succinct as possible, I begin by establishing the equation of the transmission of work, taking into consideration all the losses of living-force which can be produced in the air-conduits, and of the work consumed by the passive resistances.

This question has also been treated, partially at least, by a distinguished physicist, whose still recent loss Science regrets; but, beside the fact that he did not complete the solution, he committed errors in the mechanical part of the question which it is important to rectify.

In the movement of the air through the pipes of the apparatus for warming and ventilation, where recourse has not been had to machines, the motive force is due only to the difference of the pressures, densities, or temperatures, and after finding the expression for them we must equate it to all the losses of living-forces which may be produced added to the work consumed by the resistance of the walls.

The losses of living-force are or may be very numerous, but we have rules for calculating them. It will be sufficient if I enumerate them. They are produced —

1. At the entrance of the pipe in consequence of the contraction there, which is scarcely ever avoided. The expression is (as is known) of the form $M\left(\frac{1}{m}-1\right)^2 U^2$; M being the mass of air passing in 1 sec.; U the mean velocity in the pipe; m the co-efficient of contraction at the mouth.*

2. At leaving the chimney or pipe, the air possesses a living-force which is not utilised, and which is greater in proportion as the orifice is more contracted.

3. When the orifice of entry of the air into the pipe has a section notably smaller than that of the pipe, the loss of living-force after passing this orifice may be very great. This happens especially when the air has to pass through a grate loaded with fuel.

4. Every bend also produces a loss of force, and when there are several the loss may be sensible.

5. The meeting of two currents often produces an analogous effect.

6. Every enlargement of a pipe has also an influence of the same kind.

7. As to the resistance of the walls, we know how to express the work which it absorbs; but up to this time the constant co-efficient which enters into this expression has only been determined by the experiments of Girard and of d'Aubuisson, made on pipes of polished sheet iron, and a valve has been admitted for this co-efficient $\beta = 0{\cdot}0031$.

The experiments of the late M. Darcy on the movement of water in conduit-pipes having shown that the presence of the slightest deposits, such as would diminish the polish of the surface, might triple the value of the analogous co-efficient in water, it is natural to think that the wrinkled surface of pipes of masonry (such as the air flows through in such apparatus), such as are now in question, may have an analogous influence. This is also sufficiently shown by the experiments of M. Peclet.

Taking into consideration all the circumstances of the movement of air, we find for the expression for the volume of air at the temperature of the chimney, which is discharged in one second, by a pipe or by a chimney, under the sole action of the difference of densities, a formula of the *form given at foot of this page.*

Where	Q represents	the volume of air which escapes in 1 second; in cubic mètres.
"	A	the mean section of the chimney.
"	U	the mean velocity in that section.
"	D and T	the density and temperature of the external air.
"	d and t	the density and temperature of the air in the chimney.
"	a	0·003665 the co-efficient of dilatation of air.
"	m	the co-efficient of contraction at the entrance of the chimney.
"	A_1 and m_1	the area and co-efficient of contraction for the exit from the chimney.
"	A′ and m'	the area and co-efficient of contraction for an orifice of entrance differing from the section of the chimney.
"	m''	0·65 a co-efficient of contraction for an elbow.
"	O	the area of a passage greater than that of the chimney.
"	S and L	the perimeter and length of the pipe whose section is A.
"	β	the co-efficient of friction of the air against the walls.

Many of the terms in this formula may be repeated a number of times, others may not exist; according to the arrangement of the pipes.

In seeking to appreciate the influence of the various terms which enter into this expression, we recognise at once, as was evident *à priori*, that the volume of air Q, at the temperature of the chimney, which can pass through the pipe, is nearly directly proportional to its transverse section, and as we may almost always control this section, there results a great facility for obtaining such results as we may desire.

As to the numerator of the fraction which is under the radical, it shows that the velocity in a pipe increases only with its square root, and consequently less rapidly in proportion as it is greater.

This numerator having for its value

$$2\,g\left(\frac{D-d}{d}\right)H = 2\,g\,a\,\frac{(t-T)\,H}{1+a\,T}$$

it is seen at once that it increases: 1st, proportionally to the square root of the height of the chimney (or orifice of discharge) above the entrance opening, which was known before; 2nd, proportionally to the factor $\frac{t-T}{1+a\,T}$, and that the height H of the chimney being once determined, if we wish to make the velocity of the air nearly constant, this factor must have the same value, whatever be the external temperature T.

In the applications to ventilation where the temperatures of the external air are most

* This is the proper place to remark that Mr. Peclet, in the formula given in his 3rd edition, p. 114, supposes that this loss is expressed by $M.\ \frac{1}{m^2}\,V^2$, which leads to a serious error, and is reproduced in the most of his other formulæ.

$$Q = AU = A\sqrt{\frac{2g\left(\frac{D-d}{d}\right)H \text{ or } 2ga\frac{(t-T)\,H}{1+a\,T}}{\left(\frac{A}{m'_1}\right)^2+\left(\frac{1}{m}-1\right)^2+\left(\frac{A}{m'A'}-1\right)^2+\left(\frac{1}{m''}-1\right)^2+\left(1-\frac{A}{O}\right)^2+\frac{2SL\beta}{A}}}$$

* Translated for the Journal of the Franklin Institute, U.S.

frequently such that the term $1 + a\,T$ differs little from unity,* it will be seen that we may always secure the same velocity and consequently the discharge of the same volume of air at the temperature of the chimney, by maintaining the excess of the temperature of the chimney over that of the external air, constant.

Whence results this practical rule, very simple, but only true within certain limits: "To obtain in a given and established system of ventilation by draft the discharge of the same volume of external air, whatever may be the variations of the external temperature, it is necessary and it is sufficient to regulate the working of the heating apparatus, so that the excess of the temperature of the air in the chimney over that of the external air may be constant."

This rule is in accordance with a great number of experiments.

As to the denominator, all whose terms are positive, it may in certain arrangements of the pipes acquire a value sufficient to diminish materially the velocity of discharge.

By introducing into it numerical values, and by supposing between the sections of the passages ratios which are frequently met with in practice, I have shown that in quite common circumstances the velocity of discharge may be reduced to 1-4th of the value which it would have if these causes of loss were suppressed, and that often it does not exceed 1-10th of this value.

I have just said that the practical rule which I announced was only true within certain limits: in fact, the volume of air discharged by the chimneys to which it applies, is not that which it is important to render constant in ventilating apparatus. This volume is that of the warm air which is discharged by the chimney, while the volume of air which assures the ventilation of inhabited buildings is that which is introduced to replace the vitiated air discharged.

Now, it is easy to see that this latter volume, which is at a temperature T lower than that of the chimney t, is less than the first in the ratio, $\frac{1 + a\,T}{1 + a\,t}$, whence it results that its expression is

$$Q' = A\sqrt{\frac{1 + a\,T}{K}}\,\sqrt{2\,g\,a\,H}\,\sqrt{\frac{t - T}{(1 + a\,t)^2}}$$

and that it is susceptible of a maximum corresponding to the value $t = \frac{1 + 2\,a\,T}{a}$,

which maximum is $Q' = \frac{A}{K}\sqrt{\frac{g\,H}{2}}$,

K representing the radical which forms the denominator of the preceding equation for the value Q of the air at the temperature t.

This maximum value for the effect of a chimney has this remarkable about it, that its value is absolute and completely independent of the disposition and arrangement of the apparatus: if the temperature of the external air is 0° Cent. this value is 272°; if $T = 10°$, $t = 282°$; and these values are nearly those of the mean temperatures which are established in the chimneys of well-constructed steam engines.

Influence of the Section of the Chimney on the Economy of Fuel.—The size of the transverse section of the chimney has not only a favourable influence on the velocity of discharge, but it also has a much more direct and preponderant one on the volume of the air discharged, and this has a notable influence on the economy.

In fact, as the volume of air evacuated from the rooms to be ventilated increases only with the square root of the factor $\frac{t - T}{(1 + a\,t)^2}$, whilst it increases in proportion to the mean transverse section of the chimney, it is easy to see that whilst an increase of temperature from 20° to 80° augments the volume of air at 10° drawn in only as 1 to 2·19, we should obtain nearly the same increase by doubling the section of the chimney. But this last method would be only an expense to be submitted to once; whilst the increase of the temperature of the air from 10° to 20° and from 10° to 80°, would increase the expenditure of fuel in the ratio of 10 to 70, whilst the effect of ventilation would increase only as 1 to 2·19.

There is therefore a great advantage in employing chimneys of large section and moderate temperatures to obtain the effects of ventilation by draft.

It must, however, be remembered, that the stability of the ventilation requires that the velocity in the chimneys of discharge shall not be less than 2 m. or 2·5 m.

Application of the Theoretical Formulæ to different cases; and comparison of their results with those of observation.—After having explained the rules to which theory leads, passing to the application of the general considerations to several peculiar cases, I examine in the first place that of a straight chimney under ordinary conditions, and I come directly for this simple case to the following formula:—

$$U = 0{\cdot}9544\sqrt{\frac{D\,H\,(t - T)}{L + 16{\cdot}11\,D}},^{*}$$

which expresses the mean velocity in the vertical pipe of a chimney in functions of its dimensions and of the difference of the interior and exterior temperatures.

Now in seeking to modify, by the discussion of a great number of observations, a formula given by M. Peclet in the first edition of his *Traité de la Chaleur*, the inaccuracy of which this physicist had since recognised, a skilful practical man, M. Guerin, engineer for the house L. Duvoir-Leblanc, reached the following rule:—

$$U = \sqrt{\frac{D\,H\,(t - T)}{L + 16\,D}};$$

which is, so to speak, identical with that to which the principle of living-forces leads.

Comparison of the different arrangements employed to produce the draft of the vitiated air.—Among the different means of determining the movement of the air in draft-chimneys, there are two which have been applied in many large establishments, sanitary and others.

In the one, the furnace which excites the draft is established in the upper part of the building; this has received, with more or less correctness, the name of *draft from above.*

In the other, the furnace is established in the cellar of the building, and all the vitiated air to be extracted is brought there by descending pipes: it may be called *draft from below.*

Between these extremes there was a third which it was desirable to study, and which consists in placing the furnace on the same level with the air to be extracted; this, in imitation of the names which we have mentioned, may be called *draft from the level.* This system has been employed in the Polytechnic School, and has just been introduced into the offices of the Northern Railroad.

By applying to these three systems the considerations which we have mentioned, and supposing them of equal proportions in all other respects, we are able to calculate the velocities of the discharge of the air from the different stories of the same building; and, according to the data which we have admitted for the three cases, we have been able to form the following table, which permits the appreciation of the effect of these three systems:—

	Velocity of the discharge of the air		
	Draft from below	Draft from the level	Draft from above
Basement .	2·593 mètres	2·684 mètres	2·251 mètres
First storey .	2·508 „	2·450 „	2·144 „
Second storey	2·431 „	2·119 „	1·994 „

This table shows that, of the three systems of draft indicated, according to the hypotheses, and with the same numerical data nearly approximating to the circumstances which may present themselves in practice, that in which the air drawn out is heated on the level of each storey, will cause, for the same expenditure of heat, a rather greater velocity for the basement, about the same for the first storey, and a little less for the second storey, than that in which the draft is produced from below. As to the system in which the furnace is placed above the stories to be ventilated, it will cause, as was to be expected, velocities in all the cases rather less than the other two systems.

The system of *draft from the level* appears, therefore, to be the most advantageous of the three: its superiority and that of the draft from below over that of the draft from above is to be entirely attributed to the fact that in the two first systems, the heights of the discharge chimneys permit more advantage to be taken of the specific levity given to the air; but it must not be forgotten that, as the walls of the chimney cool the air which passes through them, the velocity may thus be diminished, and the advantage of this arrangement somewhat reduced.

However this may be, it appears to me to result from this discussion that the system of draft from the level ought to be preferred to the two other systems: its introduction presents no difficulties of construction, and, according to the examination of the proposals for the offices of the Northern Railroad, it appears to be both more economical in cost of construction and of daily expenditure: the great height of the chimneys must also give great stability to the effects.

(To be concluded in our next.)

* It is necessary to notice here a fault of considerable gravity in the formula of M. Peclet. This physicist, in his 3rd edition, vol. ii. p. 37, introduced into the numerator the factor $\frac{t - T}{1 + a\,t}$ in place of $\frac{t - T}{1 + a\,T}$, which, if applied to chimneys in which the air is strongly heated, might lead to important errors.

* In the formula of Peclet, and consequently probably here, L expresses the length of the flue which opens into the chimney below, the diameter of which is supposed equal to that of the chimney. D is the length of the side of the chimney supposed square, t and T, as before.—ED. F. I. J.

ON AN ELECTRIC LIGHT REGULATOR.

BY M. SERRIN.

THE electric light is quite a modern discovery. About the year 1730, when it was first observed in England, it was possible to obtain only a few phosphorescent gleams. In France, in Dufay's hands, these gleams became sparks darting from the body and face of an electrified person. These sparks then shone brighter in the Leyden jar, and, as the machines became more perfect, gradually developed into two great discoveries of the age—the voltaic pile and electro-magnetic action; so that by means of electricity we now obtain the most dazzling light and the intensest degree of heat. Hardly thirty years since, the luminous and calorific effects of powerful batteries were first studied, and contrivances are already devised for the purpose of rendering these effects continuous and constant. M. Serrin's regulator, which we propose to describe, is one of the latest inventions, and is distinguished by new and ingenious solutions of the chief difficulty of the problem.

Before describing the mechanism which gives a distinctive character to M. Serrin's regulator, let us briefly indicate the general conditions which a regulator of the electric light ought to fulfil.

There must be a pile having at least 50 Bunsen's elements of ordinary size to produce a good light. 100 elements united in tension give a more brilliant light; but this, again, is far surpassed by arranging them in two batteries each of 50 elements, so as to produce quantity.

It is well known that the current produced by such batteries is in some degree like the lightning's stroke, and that there is real danger in closing the circuit by touching the positive pole with one hand and the negative pole with the other. Nevertheless, this energetic power, incessantly reproduced, manifests its presence by no external sign, whilst it is propagated through a circle formed of thick metallic wires. It shows itself with violence only on closing and breaking the circuit. If sharply closed, only a bright light is seen; if the circuit be suddenly broken, a bright light is also visible, generally of a different aspect; but if the two wires, or rather the two bodies which should complete the circuit, are made to approach each other, so that the circuit, precisely speaking, is neither wholly open nor wholly closed, then the double phenomenon becomes permanent and the light extremely

brilliant. No matter can resist this heat incessantly renewed, which is maintained as long as the action of the pile lasts—that is to say, for days together.

Thick rods of gold, iron, and platinum melt like sealing-wax, and their vapours give various colours to the luminous envelopes which seem to unite the two poles. Silica, alumina, and the greater number of the most refractory substances, taken separately, are alike fused and volatilised. There is, however, one substance—the only one, perhaps—which in some degree resists the action of this furnace, and which, by a conjunction of favourable circumstances, is a good conductor of electricity (a condition indispensable to the object in view), can be fashioned in any form, and is, moreover, neither rare nor dear. This body is charcoal, such as concretes in gas retorts, or which can be prepared in pieces by particular processes. Round or square perfectly even rods are made of it, about thirty centimètres long, and varying in thickness from five to ten or twelve millimètres. Two of these rods are adapted at one of their extremities to suitable metallic pieces, one terminating the positive wire, the other the negative wire of the pile. These wires of good red copper, from three to four millimètres in diameter, covered with silk or cotton, may be several hundred mètres, or even several kilomètres long, according to the distance between the pile and the extremities of the wire. The positive and negative charcoals are generally superposed vertically. Were their free extremities planed and placed in perfect contact, the current introduced by means of the commutator would not manifest itself: it would pass into the charcoal as into the copper wire, without giving any outward sign of its presence. The circle would be completely closed.

But if in the apparatus or regulator containing the charcoals there is an electro-magnet provided with a movable armature conveniently disposed, the passage of the current would cause the armature to fall, and this movement communicating itself, for instance, to the supporter of the lower charcoal, would depress it from two to three millimètres, whilst the supporter of the upper charcoal remains fixed. It is clear that the free extremities of the charcoal being no longer in contact, the circuit will be broken, light will burst forth, and that the phenomenon will persist, under the single condition that the circuit is neither completely closed nor broken—that is to say, beyond the limits which the current can traverse.

The better to appreciate other phenomena, let us now carefully examine the effects produced on the charcoals.

Charcoal resists fusion, but it is acted on by a kind of molecular disintegration, which rapidly wastes it, the result either of the simple action of the intense heat or the current itself, which tears off and transforms the last material particles. The wear is unequal, that at the positive being generally about twice as great as that at the negative. The combustion of charcoal by the oxygen of the air is of little account, for no marked difference is observable when the charcoals are kept in an atmosphere of nitrogen. It will be observed that the incandescence of the positive pole occupies more length than that of the negative, as if the latter underwent a less degree of heat. In consequence of this destructive process, the space between the two charcoals becomes in a few minutes enlarged. At first only two or three millimètres, the distance soon increases to eight, ten, or even more, according to the nature of the charcoal and the force of the current.

To observe these phenomena to the greatest advantage, we must project on to a screen the image of the charcoals magnified eight or ten times, when the light becomes supportable, so that observers can study with facility the series of appearances which present themselves in this focus of light and heat, apparently so constant, yet so agitated. We cannot now enter into the details of the curious observations which have been made on the impurity of charcoals, on the coloration of the flames by the substances introduced into them, on the fusion of bodies placed, not in contact with the charcoals, but in the intervening space. We will confine ourselves to stating that the intensity of the light is notably diminished by a kind of waster, which forms from time to time on the point of the negative charcoal by the accumulation of particles from the positive charcoal, as if by the current. These wasters disappear and reappear at intervals, but they are very rarely observed with certain charcoals and at certain degrees of intensity of the pile; consequently, careful selection of the charcoal must be made in order to secure a more constant light.

The interval between the positive and negative extremities cannot be indefinitely increased in the regulator, and for two reasons:—1. The intensity of the current diminishes in proportion to the extent of this interval. 2. The intensity of the light diminishes with the force of the current. It is necessary, then, to limit the increase of the space to prevent the diminution of the light. This is one of the most important and one of the most delicate functions of the regulator; and for this purpose M. Serrin's mechanism is unrivalled in ingenuity. It is evident that the electro-magnet previously mentioned is the regulator of the motive power to coadapt the charcoal; but this adaptation is a very complex process. 1. The centre of the focus of light must remain at the same level. 2. The charcoals must not come into contact, as the circuit would then be completely closed and the light extinguished, at least for a moment. 3. The movement must be made exactly at the right instant; that is to say, before the current has undergone a certain, hardly perceptible, diminution.

It is especially in accomplishing the last condition that M. Serrin's regulator acts with unequalled precision.

The armature of the electro-magnet can be likened to the scale of a balance with a fixed weight, of which the balancing space is limited to 3 or 4 millimètres by tangent screws, and which, instead of having counter weights on the other side, are supported by two springs, one fixed nearly in equilibrium, while the other receives a variable tension by a movement of the screw. Such a scale is easily made to descend by the superaddition of 10, 20, or 30 grammes, according to the degree of tension to be given to the second spring. Such is the principle on which M. Serrin has formed his ingenious apparatus. His armature is connected with all the supports of the negative charcoal, and oscillating vertically and freely within the narrow limits of 3 or 4 millimètres, the two springs keep it raised, and the superaddition making it descend is the attractive force of the electro-magnet. This force decreases with the force of the current; consequently it decreases when the charcoals, from being worn away, leave too great a space between them, and the light begins to fade.

The variable tension of the spring is, in fact, regulated by this datum. The instant this minimum is reached the scale ascends; that is to say, the spring raises the armature, the surcharge due to the electro-magnetic force having become insufficient to restrain it.

These improvements seem to us all the more important, since M. Serrin, in constructing his regulator, has succeeded in uniting the freedom and accuracy of the automatic movements with a solidity which excludes all accidental causes of derangement.

We have proved that this apparatus is not less fitted to receive the induced current proceeding from powerful magneto-electric batteries set in motion by a steam-engine of three or four horse-power. In this case, the current is not continuous, but alternately positive and negative. There is no need of much complication in these batteries to rectify the current, leaving it in its original uncontinuous state; but in this case rectification is useless, the regulator adapting itself perfectly to the disconnectedness and to the alternation.—*Comptes-Rendus.*

PETROLEUM AND LIVERPOOL.

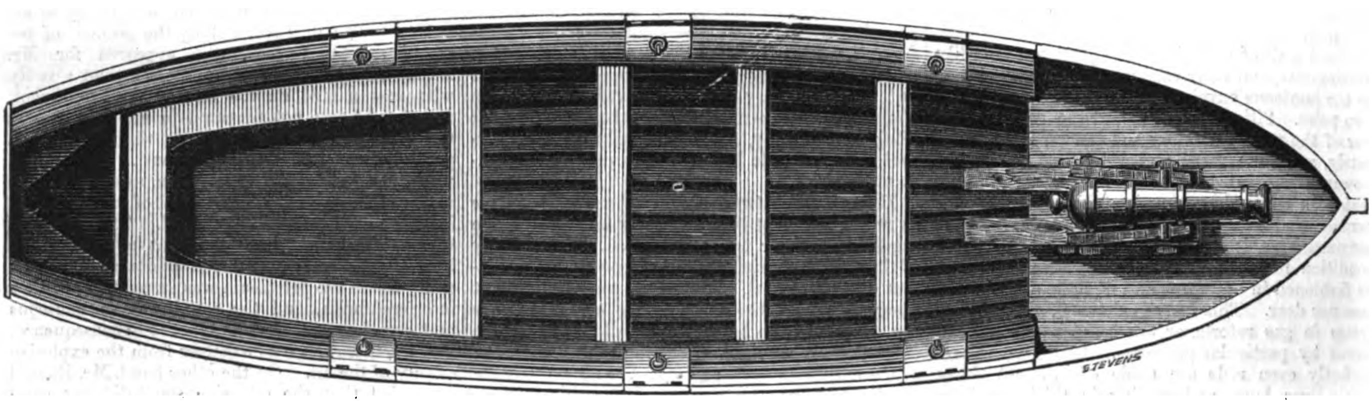
SINCE our article in last week's MECHANICS' MAGAZINE was written, several important proceedings have taken place in Liverpool relative to the Petroleum question. At the Liverpool Assizes we find that John Bigham, a Liverpool merchant, appeared to answer an indictment charging him with causing a serious nuisance and injury to the public health of Liverpool by the storage of petroleum. Mr. Russell, who appeared for Mr. Bigham, said that there were no less than seventy witnesses named on the back of the indictment, and that he was not prepared to meet the case at the present assises; he asked, therefore, for a postponement until the winter court. Mr. Littler, who appeared for the prosecution, said that if the case was postponed, a great deal of mischief and inconvenience might be created. The nuisance was so great that for the extent of a mile the health and comfort of the inhabitants in the vicinity where the petroleum was stored were greatly interfered with, and the smell was so nauseous that even horses lost their appetite in consequence. Besides, there was also a danger from the explosive quality of the oil. On the other hand, Mr. Russell contended that the offensive smell did not arise from the storing, but from the manufacture of the oil, and that, though the process of manufacture was conducted near the defendant's premises, he had no personal interest or control over it. Mr. Liddell, Q.C. (who sat as judge), retired for a few moments to consult Mr. Justice Mellor, and on his return intimated that he should call upon Mr. Bigham to enter into recognisances to appear at the next assizes. In the meantime, however, should any serious or special damage arise from the storage of the oil, the defendant would be held responsible. Mr. Bigham was then formally bound over to appear, or forfeit 500*l.*

At the magistrates' chambers, on Wednesday week, Mr. M'Gowen appeared before their worships in support of an information laid under an Act of Parliament, passed on July 7 last, against Mr. B. Platt. The act — the Liverpool Fire Prevention Acts Amendment Act, 1862 — enacted "that it shall not be lawful for any person to carry on in any place other than a building detached by seventy-five feet from any other building the trade, business, or employment of the boiling of oil, blubber, or tar, or the distilling of turpentine, or the manufacture of vegetable or mineral naphtha, or of varnish, and the distilling or manufacture of petroleum and its products." The defendant, Mr. Platt, had premises in Greenland Street, off Parliament Street, for refining petroleum, and these premises were within the distance mentioned in the Act of Parliament. Mr. Sandys, who appeared for the defendant, did not deny that the premises were within the specified distance, but complained that, as the Act of Parliament had only come into force the day before, reasonable time had not been allowed, and he asked for an adjournment to allow the defendant time to work the stuff up. Mr. M'Gowen said notice had been given in the newspapers. After some conversation, the bench consented to adjourn the case for seven days.

The next day this much-vexed question came before the Liverpool Health Committee, a report being submitted by the Town Clerk, which stated that, "as the medical officer was not in possession of evidence to show that the effluvia were injurious to health, no proceedings could be taken under the Liverpool Sanitary Act; and as under the General Nuisances Removal Act the justices can only insist on being satisfied that the defender has used the best practical means for abating such nuisance, the Health Committee could not effectually deal with the subject. To proceed by indictment at common law was an expensive process, and one which the committee could not enter upon without the sanction of the Council. Steps had been taken to lessen the nuisance in Greenland Street, where a refinery had been set up, the owner having been summoned, and having obtained a week's indulgence before being made amenable to the provisions of the new Local Fire Prevention Act."

The Chairman said, he thought it might be suggested to the Council to provide a place for the storing of petroleum, such place to be ventilated by means of a large shaft, so as to prevent a nuisance. It was then agreed to send a deputation to the Finance Committee, and confer with those gentlemen upon the Chairman's suggestion.

AN IMPROVED LIFE BOAT.



Mr. A. Lamb, of Southampton, and Mr. J. White, of West Cowes, Isle of Wight, have patented "Improvements in Life Boats," which they describe as follows: —

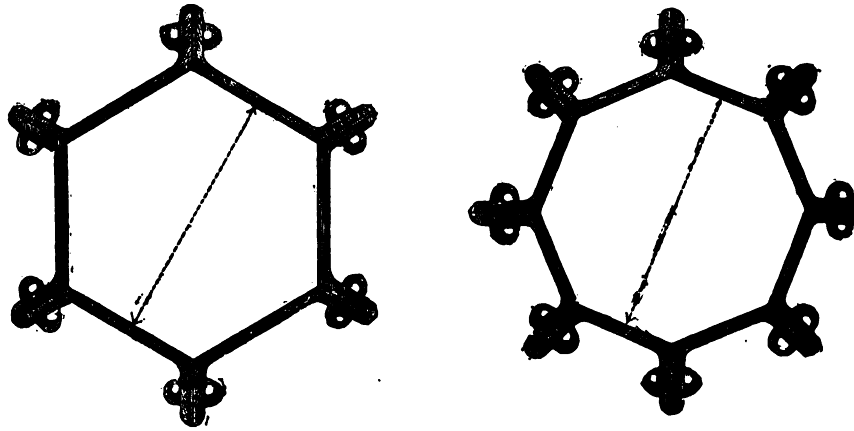
This invention relates to certain improvements in the construction of sea-going life boats, by which, in addition to their quality of safety for life-saving purposes, they are adapted for war purposes, being capable of carrying securely a piece of ordnance in the bows.

We construct life boats, with longitudinal water-tight compartments or air chambers formed on each side of the boat, and extending from stem to stern, or between the bow and stern compartments, and carried up to the gunwale; these are combined with bow and stern water-tight compartments extending from side to side of the boat; these bow and stern compartments should be only of such a height from the bottom as to leave a space below the top side of the gunwale, the space thus left being made available for seats when not designed to be otherwise employed; or in certain cases these compartments may at the sides extend above the line of gunwale, leaving a flat space or recess sufficiently below the line of the gunwale to enable the weight of persons seated in such recess to be kept as low as possible. For the purpose of carrying a gun forward, the water-tight compartment of the bows is extended in length sufficiently far aft to provide a suitable bearing for the gun carriage, and to enable the gun to be worked clear of the mast, and by the additional buoyancy, which is obtained by the increased capacity of this compartment, the gun may be floated in the event of the longitudinal water-tight compartments becoming damaged by shot, or their floatative power otherwise destroyed.

In constructing boats, we insert several air-tight transverse partitions, bulkheads, or divisions, and introduce into each separate air-tight chamber or space thus formed, a "water-tight scuttle" or cover. Each separate chamber thus formed may be employed as a locker for stowing ammunition, dry provisions, sailor's kit, and for other similar purposes. By the division of the longitudinal air cases or chambers the safety of the life boat is increased, and when employed as a gun boat, or when riddled by shot, the stowing-in or piercing of one or more compartments will still leave the buoyancy to float the gun and boat's crew.

By this invention we combine with a man-of-war's pinnace or other boat armed with a gun all the qualities of a life boat, and so enable ships' boats thus constructed to carry and work their guns with greater safety. Each of the divisions of the longitudinal air cases may, in addition to the "water-tight scuttles" on the upper side, have water-tight plugs or valves fitted at the lowest part of each of the divisions of the longitudinal air cases, so that perfect ventilation of the interior may be insured when the boat is out of use. Two or more delivery tubes may be fitted in the bottom of the boat with valves so constructed as to prevent the admission of water from without and free the boat from water, with which she may be partly filled from shipping a sea or from other causes. These tubes may also be availed of for the purpose of taking soundings through them instead of over the side of the boat, as is usually done. Tubes may also be so placed with reference to the centre of displacement of the boat to enable a bower anchor slung under the bottom to be carried out (say to a ship in distress), the ropes and slings passing through these tubes. These latter tubes, as well as the delivery tubes, always serve (independently of any other purpose to which they may be put) to supply air to those who may be confined within, in the event of the overturning of the boat.

HUGHES'S MALLEABLE CYLINDER AND TUBES.

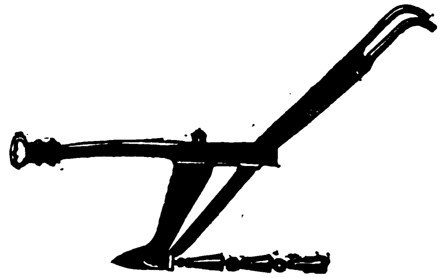


HUGHES'S MALLEABLE CYLINDER AND TUBES.

This invention, by Mr. E. W. Hughes, of Parliament Street, Westminster, consists in constructing cylinders or tubes suitable for columns or supports used in engineering and architectural structures, by forming and combining plates of wrought or malleable iron, each of which is rolled with two outer projecting flanges, which are produced at angles greater than a right angle to the plane or outer surface of the plate. The angle at which each flange of an iron plate will stand to the plane or surface of the plate will depend on the form of the intended column or similar tubular support which is to be made; but in all cases the outer or butting faces of the inclined flanges of the plates used will require to be radial with the centre of the column or similar tubular support.

The above engravings illustrate sections of two columns, one section having eight sides and the other six sides.

CARTER'S PATENT DRAINING PLOUGH.



The above engraving illustrates a plough recently patented by Mr. J. Carter, of Tipton, Staffordshire. It has a frame similar to that of an ordinary plough. To the frame a coulter or knife is attached, which coulter cuts into the earth to the required depth. The foot of the coulter is expanded or enlarged at its back (as represented in the engraving) into a conical form, and to the back of the foot of the coulter a series of balls or drags are attached, the drags being chained end to end. They are of a conical figure, the apex of the first cone being linked to the foot of the coulter, and the apex of each succeeding cone being linked to the base of the preceding one. The cones are of gradually increasing size as they are more distant from the coulter. As the plough is drawn through the earth the coulter cuts down to the required depth, and, drawing after it the balls or conical drags, a pipe-like channel is formed, by which the land is drained.

CUNNINGHAM'S PATENT SCREW PROTECTOR.

Fig. 1.

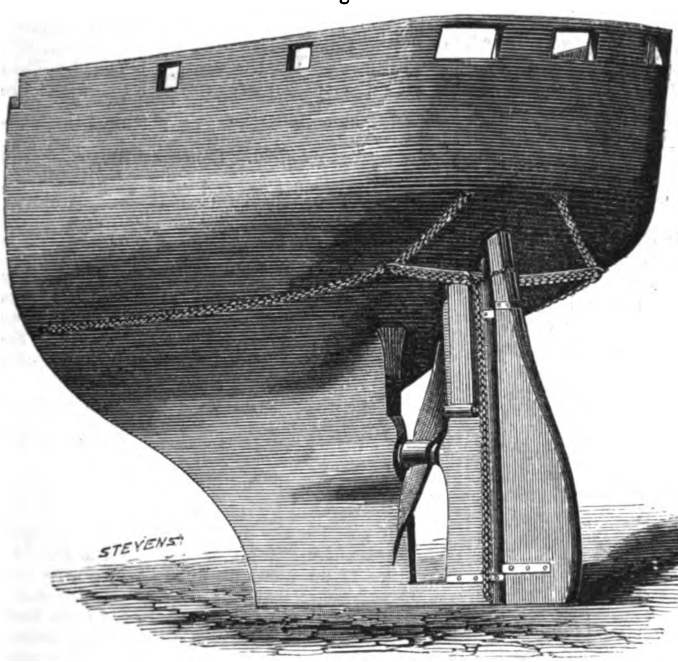


Fig. 2.

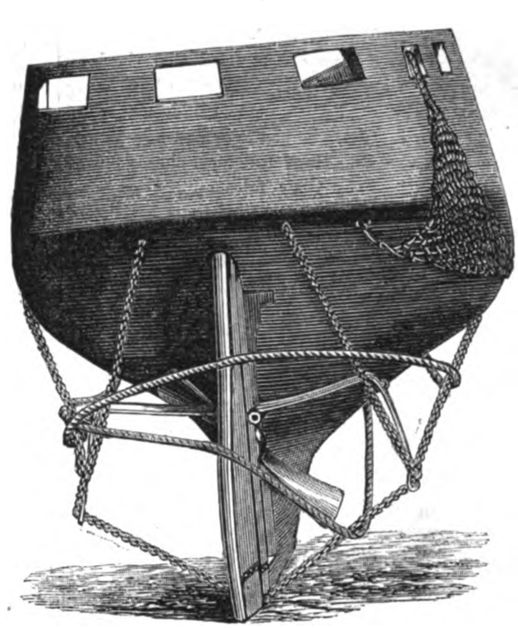


In consequence of the remarks of our correspondent, Mr. Hewitt, Mr. Cunningham fears Mr. Hewitt does not understand his invention for protecting screw propellers, and has, therefore, forwarded us photographs, from which the accompanying engravings have been made.

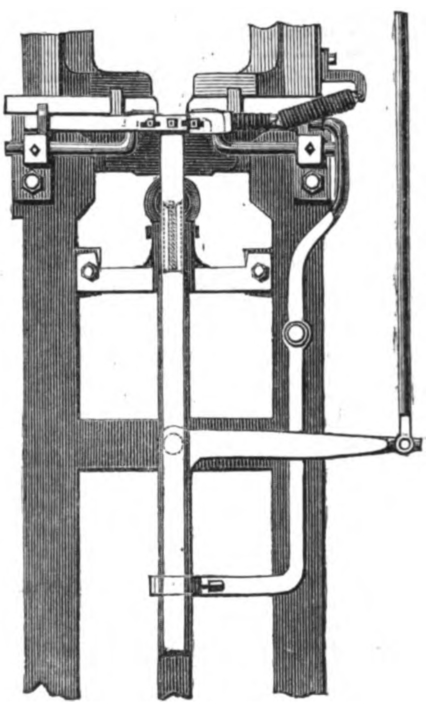
Fig. 1 shows the protector down on guard. Hawsers are represented in positions to foul the screw; the fouling, however, is prevented by the protector. On the starboard side, netting to guard off wreckage, &c., is shown ready for instant application, if necessary. Fig. 2 shows the protector raised when the ship is at sea, so as to offer little or no impediment to her progress through the water. The protector would only be lowered when entering a channel, harbour, or other spot where fouling might be expected, or in the case of ships in war, before going into action.

We have seen no plan for the purpose which seems likely to succeed as well as that of Mr. Cunningham.

IMPROVED MACHINERY FOR THE MANUFACTURE OF BRADS.

MR. W. GORSE, of Minworth, Warwickshire, manufacturer, has patented an improvement or improvements in machinery for manufacturing the cut nails called brads, which machinery consists of an arrangement of parts for guiding and giving a compound motion to the strip of iron from which the brads are cut. The motion given to the strip consists of the ordinary swivel motion, that is, a motion whereby the end of the strip is presented obliquely to the cutters, in combination with a side or lateral motion, whereby the strip is carried backwards and forwards, so as to be operated upon alternately by the bill cutters situated on either side of the bottom or fixed cutter. The object of this motion is to secure uniformity in the size of the heads or bills of the said brads, which cannot be effected in machinery of the ordinary kind.

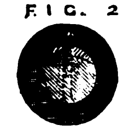
The strip passes through an elastic guide, and the guide is moved laterally by means of a lever which takes motion from the ordinary swivel lever. The lateral motion, combined with the ordinary swivel motion and with the elastic guide, effects the cutting of brads having heads or bills of uniform size, although the strip from which they are

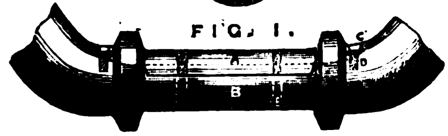


ut may not be of uniform width. The elastic guide is constructed in the following manner:—The guide consists essentially of a bar in which two pegs are fixed, between which pegs the strip is held. The direct motion of the bar is produced by the lever before described, and the return motion by a spring. One of the pegs by which the strip is supported is fixed, and the other is capable of a sliding motion on the bar, being kept to its bearing by means of a spring. The strip is gripped between the fixed and elastic pegs, and the guide is elastic in its direct motion by the yielding of the sliding peg, and is elastic in its return motion by the elasticity of the spring effecting the said return motion.

AN IMPROVED CRANK AXLE.

FIG. 2





THIS invention, by Mr. J. Bird, of Blidworth, Nottingham, consists in forging the axles between each pair of collars, where collars are used, and where collars are not used, at each extremity of the axle, of an oval form, on the side where the wear will mainly be, as seen at B, figs. 1 and 2 of the above engravings, and of a semicircular form on the other half thereof: thus the axle is of an oval form on the side upon which the most wear is, and of a semicircular form on the side upon which the least wear is; each collar has a recess forged or otherwise formed in it to receive snugs C, which are cast or forged on the ends, and form part of a piece of iron or other metal A, which is shaped in such wise that when one of such castings or forgings is laid on the axle formed as above described, the casting or forging will form the axle round. The piece is secured to the axle by a screw D passed through the snug and into the axle-shaft outside the collars, where collars are used; in wide axles the piece is secured by additional screws E, which are passed through the axle and into the piece, whereby when the piece A is worn nearly through by the pressure of the bearing upon it, it can be readily replaced by another piece.

The workmen of the Viaduct Works, Crumlin, Monmouthshire, have recently celebrated the completion of an iron railway bridge for Portugal by a dinner. The order for a new bridge was received at Crumlin on the 12th ult.; and by the 1st inst., or in eighteen working days, the work was ready for shipment.

New York has now, after being urged, it is said, for ten years, introduced steam instead of hand fire-engines. These steam fire-engines now made are said to be more compact than those which were first introduced. They use steam at a pressure of about 100lbs., and the greatest favourites have horizontal cylinders, and are direct acting.

THE TRUE PRINCIPLES OF AIR NAVIGATION EXPLAINED.

TO THE EDITOR OF "THE MECHANICS' MAGAZINE."

Letter 2.

Sir,—Perhaps it may be asserted that the laws of mechanics and the rules of algebra have never been carefully applied to the achievements of flying animals; but, whether so or not, here is evidence of a very important and most simple law of nature mystified by their false application, and rendered totally incomprehensible to us because of their erroneous interpretation, but which, if correctly interpreted, is so constituted as to be the means of inestimable advantages to mankind, both morally and commercially.

That very important property peculiar to aeriform bodies evidently has never been recognised in this field of enquiry, viz. the *elasticity* of the air. Indeed, I firmly believe that the operation of this property in generating a fulcrum for resisting the actions of flying animals, has never been even suspected, and therefore never before discovered; for all to whom I have communicated my theory reject it as untenable, when considered apart from a vessel employed to confine it. I must acknowledge, however, that I have, during the last three years, laboured under the inability to express my views in simple and intelligible terms, having been, in the absence of any information experimentally obtained till now, unable to verify it.

This *anti-gravitating* property enables the air to repel its particles with equal force in every conceivable direction, through all variations of temperature, altitude, or volume, and therefore to resist any surface rightly employed to displace or compress it, with a force increasing in the exact ratio to its density or compression; and such compression is increased in proportion to the velocity of the impelling surface. The atmosphere enveloping the earth, is by its own weight, at or near the level of the sea, compressed with a force equal to about 14½lbs. upon the square inch, and consequently a surface propelled in any direction must increase its compression in the direction of motion. The additional compression to which the air is then subjected, will of course depend on the velocity of the impelling surface, which will and must exceed the velocity of the air therefrom acquired, else no equilibrium would be disturbed, or resistance to that surface experienced; but, in relation to that surface, i. e. if moving at equal velocities, the air would be as if stationary, as when a balloon floats in the air. Nor can the air have a greater velocity than the impelling surface, because the friction amongst its particles tends to retard it.

When a bird works its wings, its strength is distributed over their entire surface, and, whatever be the resistance offered by the air to those wings, such resistance will be entirely due to the *elastic force* of the column of air covered by the surface of those wings, which alone counterbalances the gravitating influence of the earth upon the bird to the extent of the *power* by which the wings are worked.* Now as the *strength* of the bird is distributed over the entire surface of its wings, so also is its weight; for the wings support the body when it is sustained in the air, and the resistance opposed by the air to that surface equals the power impelling that surface, and consequently neutralises or exceeds the force of gravity upon the body. It is therefore clear that the power of the animal is expended in imparting motion to its propellers, and the propellers impart motion to the air, the velocity of which, as already shown, cannot exceed the velocity imparted to the propellers. The power and density of the body are therefore sustained by the elasticity (which varies with the density) of the column of compressed air covered by such surface. Consequently the density of the body must be proportional to the density of the air, and the density of the air is proportional to its compression, and its compression proportional to its velocity. Therefore the elastic force of the air is proportional to its velocity, because the velocity is proportional to the compression.

From the foregoing it is clearly demonstrable that, as the bird's weight on the surface of its wings is to the atmosphere's weight on the same surface, so must the velocity of the bird's wings under its own weight be to the velocity of the atmosphere under its own weight; for truly there is the closest connection between these quantities, and which displays their law of mutual dependence. Therefore, by multiplying the unit of the atmosphere's weight by the surface of wing, and dividing the product by the bird's weight, we find their comparative weight; and by dividing the unit of the atmosphere's velocity by the comparison of their respective weights, we get the comparative velocity, or the true velocity of the bird's propellers. Thus:—

$$\frac{P \times S}{W} = c \text{ and } \frac{V}{c} = x,$$

where P is the weight of atmosphere, S the surface of propellers, W the weight of body, V the unit of atmosphere's velocity, c the comparative weight, and x the comparative velocity.

We have no means of ascertaining the actual velocity of the atmosphere—in its own body, the open air—when set in motion by an impelling force equal to twice its own pressure; but as the air has been found by careful experiment to rush into a vacuum at a velocity of about 1,300 or 1,400 feet per second, we may reasonably allow its velocity to be reduced 10 per cent. by friction amongst its own particles, when set in motion in mid air by an impelling force equal to one atmosphere over its own pressure: if so, we have 1350—135 say 1,200ft. per second as its velocity under such impelling force. Now, if we take the unit of pressure at 14½lbs., and the unit of velocity under such pressure at 1,200ft. per second, we shall find that it gives results far more true to Nature, and surely therefore more applicable to the subject, than any formulæ given by the most "eminent authorities" respecting the resistance of the air (and which is indeed limited to surfaces projected continuously in the same direction only, or to the wind on a body at rest). I am aware that I stand alone in this view of the problem, and, being "an outsider," must not expect to meet with supporters; but I am fully convinced of its truth, and the strongest terms which can be employed against it will ever fail to disprove it.

This brings us now to the important question at issue, viz. What, then, is the true velocity required of such surfaces to raise their respective weights?

The experiments on the two birds given before show that the male bird, with a surface of wing equal to 41·75 sq. in., propelled through a distance of 1·82ft. at each stroke, was capable of raising a weight equal to 1·8lbs. What, then, was the true velocity required of that surface? As above, we have P = 14½lbs. S = 41·75 sq. in., and W = 1·8lbs., to find c (comparative weight), and, V = 1200ft. divided by c gives x the velocity required. Then if a be the space through which the wings are propelled at each stroke, $\frac{x}{a} = y$ will be the number of actions required. Consequently,

$$\frac{14 \cdot 5 \times 41 \cdot 75}{1 \cdot 8} = 336 \text{ c. w., and } \frac{1{,}200}{336} = 3 \cdot 57\text{ft., the}$$

velocity required. Therefore $\frac{x}{a} = y$ or $\frac{3 \cdot 57}{1 \cdot 82} = 2$ is the number of actions; so that four strokes only per second is required of the male bird to raise its natural weight and load, and not 29 actions or 58 strokes per second, even if it were possible for the bird to perform them, as required by the rules generally received.

The table given *below* forms a striking contrast to the preceding one, in which the resistance was taken as increasing according to the law of the square of the velocity.

By comparing these tables, we see that if the resistance opposed by the air to the surface of the wings is taken as the square of the velocity, a bird cannot raise its natural weight without the expenditure of an immense power incessantly impelling the wings, requiring the male bird to make at least 25 actions per second, and the female bird to make 24 actions per second; and if they ceased the action of their wings for one second, they would fall to the ground by the force of gravity; because they would require this constant velocity to elevate and support the natural weight of their bodies in the air, and a much greater velocity to obtain any surplus momentum for progression.

We may therefore pardon writers on natural history or air navigation for asserting that "birds are liberally supplied with air-cells for reducing their specific gravity;" for the most careless observer must have noticed that they not only possess power sufficient to fly with perfect ease, but even to gain an increasing momentum sufficient to propel the body for several seconds after all action of the wings has entirely ceased. On the other hand, if we admit the elastic property of the air to operate as freely in their behalf as it has been found to do in our experiments, we see at once an extension of the design and importance of one of the most striking features of the constitution of the atmosphere — its elasticity (without which it could have no tendency to expand)—universally adapted by the Creator for sustaining all flying animals, demanding but a moderate velocity of their wings, and enabling them to maintain their actions with perfect ease: requiring no more than two or three actions per second to raise an additional weight nearly equal to that of their own bodies.

Moreover, the resistance of the air according to the law of the square of the velocity, is only sensibly experienced with tolerably high velocities, a velocity of 5·9ft. per second, or four miles per hour, only producing a gentle wind termed "a zephyr breeze." If this law of man, which, indeed, is very limited, was a law of Nature, it is evident that the myriads of insects who pass so much of their time

Surface of wing	Weight of air on surface of wing	Weight of body on surface of wing, taken also as one for comparison	Comparative weight of body to weight of air on surface of wing	Velocity of atmosphere per second	Velocity of propellers per second required	Distance propelled through at each stroke	Number of actions per second required
Square In.	Lbs.	Lbs.		Feet	Feet	Feet	
Male bird 41·75	605·4	1·04 1·8	582 336	1200	2·06 3·57	1·82	1·14 2·0
Female bird 35·0	507·5	0·77 1·53	659 332	1200	1·82 3·61	1·57	1·16 2·3
Insect 0·125	1·8	·00018	10070	1200	0·12	·0625	2·0

* As a proof of this it may be stated, that one time when the female bird was let out of her cage, she selected one of her usual spots and alighted; soon after settling she began slowly working her wings, gradually increasing the velocity until the resistance on surface of wing exactly counterbalanced the force of gravity on the body, and during these actions, which were continued about three minutes, the bird remained as if fixed, off her feet, but only about two inches above the surface on which she had previously rested. After thus soaring, she alighted precisely on the same spot, not having effected the slightest change of position in any other direction. By keeping her body nearly in a perpendicular direction, each stroke participated equally in producing the upward or sustaining effect. The tameness of this bird was very gratifying, as she would allow me to conduct the operations of weighing her as correctly, and harnessing her to her load, as quietly as if she appreciated its importance; and when done, would often perch on my head or shoulder, and only leave me on being taken off and put into her cage.

on the wing, would do so under the penalty of the severest toil; so much so, indeed, that their delicate bodies, which contain mechanism of far less tenacity than birds, would be instantly destroyed; although the surface of wing with which they are provided is much greater than that of birds, in proportion to weight. A common blue-bottle fly (selected for experiment), for instance, had a surface of wing equal to 0·125 square inch, and measuring but half an inch each in length, could never be propelled through a greater distance—even if each wing passed through 180°—than $\frac{3}{4}$in. at each stroke; and this surface had to sustain a weight of $1\frac{1}{2}$grs., and was also further capable of raising a total weight of $2\frac{1}{2}$grs. when loaded. According to the rules generally applied (viz. $3{\cdot}3^2 \times 0{\cdot}125 \times {\cdot}00016 = {\cdot}0002$lb. or $1\frac{1}{2}$grs.) it would require a velocity of 3·3ft. per second to obtain a resistance equal to $1\frac{1}{2}$grs. on such surface, or require the insect to make 53 actions or 106 strokes per second! Consequently, if this law of the square held good in nature, the smallest and weakest insects would be doomed to much more violent and laborious exertion than birds, notwithstanding the superiority of their wing surface, the difference in this case being eight times greater in proportion to weight than that of the birds before given. How different the result if taken according to the principles of Nature, 2 actions per sec. being quite sufficient, viz.:—

$$\frac{14{\cdot}5 \times 0{\cdot}125}{{\cdot}00018} = 10070, \text{ then } \frac{1200}{10070} = {\cdot}12\text{ft. and } \frac{{\cdot}12}{{\cdot}0625}$$

= 2 actions nearly. If we carefully observe the actions of insects, we shall find that they, like birds, rest on their wings, and at frequent intervals suspend all action entirely for a time, darting about during such suspension with the greatest facility from the momentum previously obtained, and merely renewing the action as occasion requires. The actions of some insects are, however, more constant and uniform but very slow, as the butterfly, for example, whose slow movements may be distinctly observed and counted.

The examples already quoted are, I believe, quite sufficient to establish the close connection and law of dependence existing between the density of flying animals and the density of the medium for sustaining and resisting their actions, and also between their respective velocities, and place beyond the bounds of refutation, that the following are the *true* and universal *principles* upon which the success of flight depends in Nature, viz. *power* and *weight* transmitted through the medium of the propellers to compress the air, and thereby develope its *elasticity*, by virtue of which alone, the air presents to such power a substance offering an equally resisting force through the entire stroke; and as that power is, so will the resisting force or density of the air be, to the density or weight of the body employing that power—if superior the body will rise, if inferior the power will be wasted.

I shall say something on the motive power in a future letter.—Yours, &c.,

W. Quartermain.

DISINCRUSTATION FLUID.

All who visit the Western Annexe should spare a minute to glance at a case of specimen deposits removed from steam boilers by Eastern & Springfield's patent incrustation fluid. The case is near Eastern & Amos's large centrifugal pump. It is abundantly evident, from the large masses of deposit here exhibited, that this fluid is an active agent in cleansing boilers. We see that one deposit was removed from a boiler belonging to Mr. Henry Cater, of the Grove Boiler Works, Southwark. It shows how thick deposits may be removed from plates and rivet-heads without any injury to the iron works. There is another removed by the fluid from a marine boiler belonging to Messrs. Brownlow, Lumsden, & Co., Hull. But the most remarkable specimen which the case contains is an immense block removed by the fluid from a Cornish boiler belonging to Messrs. Freen & Co., Portland cement manufacturers. This block weighs 47lbs., is between 4 and 5in. thick, and it was originally 2ft. square, but was broken in transit. We are informed that this block took two months to form in the boiler, and that after the fluid was used four times on four successive Saturdays, the crust was removed by hand without chipping. The case contains a variety of other deposits, which are as many substantial proofs of the efficacy of this patent fluid to remove incrustations, which are such a prolific source of weakening boilers and producing explosions.

THE STRAIGHT LINE *VERSUS* THE WAVE LINE FOR VESSELS.

TO THE EDITOR OF "THE MECHANICS' MAGAZINE."

Sir,—Mr. Young requests to have his "say" also on this ship-building question, and he is very welcome, so far as I am concerned. He asks me "to read carefully and attentively Mr. Scott Russell's remarks on the wave-line," which very excellent advice, I presume, has been followed by himself in regard to my remarks on the same subject; yet I cannot reconcile such supposition with his saying that I "turn my attention more to the water after it has been disturbed by the passage of the vessel, rather than to the question at issue, viz. how to move the water so that the least power shall be expended in moving it." Now, as to the first point, I have referred to it only to dismiss it, as not belonging to the question; and as to the second, it is the very gist of all I have written on the subject, and what I have made the special matter of demonstration. In my first communication I proved that, taking the parabolic curve as the type of all the hollow lines (and from which they will not greatly vary), the work done by it, and, of course, the power expended by it, is double to what it is in the case of the straight line for a particular distance within which the water is moved, or rather, as it would be better to express it, for a particular distance over which the pressure acts: I speak of a particular or partial distance, and I may add thereto the particular planes, that is, the horizontal ones, on which the hollow lines are described; because the entire work done in overcoming resistance is not comprised in the investigation, otherwise I should be startled at the great disparity in the ratio of 2 to 1, and suspect some error in my conclusions. What, on the whole, may be the comparative rate in the expenditure of power it is impossible to say, but that to some unknown extent it is in the above ratio, is undoubtedly true. Now, until this conclusion be as mathematically controverted as it has been mathematically supported, it is idle work to urge anything that has merely a collateral bearing on the subject, whether it be on behalf of the wave line, or in opposition to the straight line. However, not to be uncourteous, I will proceed to consider Mr. Young's observations.

He says that in a self-formed cutwater of ice, "the lines resisting the current were hollow or wave lines, and there was no disturbance of the water, or throwing off of the ice (as was the case in the piers of the bridges with straight or convex lines), thus showing that the current passed with the least hindrance, and the pieces of floating ice continued in contact with this glacial wave-line cutwater, all the time they were passing." Now, all this is just what one might expect, although viewing the straight line with favour. The destructive tendency of the current is to remove obstacles at any cost of power; nature is not called upon to economise; and so the ice, supposed to have at first a triangular shape, is gradually destroyed just below the apex of the cutwater, where it is weak, until it takes, for that portion of it, the form of least resistance corresponding to its own strength and the velocity of the stream—that is to say, it becomes a more acute triangle, with sides not differing sensibly for some little distance from straight lines; but observe, that this can take place (assuming that the breadth of the cutwater is maintained) only with the necessary consequence of a more obtuse form being produced at a point farther down the stream, and offering greater resistance than the straight line would have done. As this result is gradual, a hollow curve line is generated, with the salient angle at the haunch rubbed off. Notwithstanding the greater obtuseness of form, and the greater resistance it opposes, the cutwater is as enduring at this point as at the apex, because of its greater strength. It is a case of give and take, the acute for the obtuse; and if the sum of resistances for each were equated in the exchange, the result of the alteration from the straight-lined triangle would be a form, not of least, nor, upon the whole, of less resistance, but of greater durability. Unfortunately, however, for the advocates of the wave-line theory, the resistance of water in opposition to motion, and the resistance to be opposed to it when in motion, vary with the squares of the velocities—a fact which is overlooked or disregarded by them; consequently, the mean resistance due to the squares of the several velocities incidental to a curve line is greater than that due to the square of the uniform velocity incidental to the straight line, and, as I have before said, in the case of the parabolic curve, it is double thereof. It may not be superfluous to add here, for the sake of imparting information in some quarters, that the velocities on which the resistances are calculated are those which are destroyed in the case of the cutwater, and generated in the case of the ship, which velocities are variable—although the velocity of the current or of the vessel is constant—on different portions of a curve line, according to their respective obliquities to the line of action. It unquestionably follows from this difference in the velocities destroyed, together with the law of the corresponding resistances, that the current would, on the whole, expend more power on such a glacial cutwater than on one with straight lines. It would expend less at the apex; hence the other form, on which it would expend more, throws off the water at that point with some degree of violence; but then the haunch is spared the excess of pressure consequent on hollow lines, and the pieces of floating ice would be less likely "to continue in contact with the cutwater all the time they were passing." The circumstance of their tendency to do so, and in aggravation of friction, although cited by Mr. Young as a sign "of the current passing with the least hindrance," is regarded by me as a proof of just the contrary. I know that Mr. Scott Russell, in his experiments, took the same view of the subject, in reference to floating pieces of cork clinging to the side of his vessel; but I take it that this is only another example of a wrong interpretation of phenomena.

Dr. Thomas Young, a long time ago, and long prior to the advent of Mr. Scott Russell, pointed out the dead water which he said forms in front of a bluff ship, as an indication of what the shape of the bow of a vessel ought to be. But such forms I consider to be only the necessary consequence of a destructive assailing force on easily disseverable materials, and are not to be followed when we become the assailants, defying all erosive action, and where the great object is to economise power. The analogy would carry us too far, and land us in error; for instance—the greater the velocity of the stream, the less will it mould such a cutwater into acuteness of form; therefore, the greater the speed required from a ship, the less acute should be its bow! Is Mr. Young satisfied with this aspect of the analogy? Will he acquiesce in this exemplar, for our imitation, as to the way in which "Nature works on unerring principles?" Nature cannot err, but we may err in misunderstanding and misapplying her principles. Wheels are better than legs, or any imitation of them, for our locomotive contrivances; and the propelling action of fins and tails is no desideratum in nautical engineering; neither do we want the bows of our vessels to be fashioned after the model of a "glacial cutwater." It would be more to the purpose to take the form of a fish, though not quite; for we wish to keep our skins dry, and fishes would rather keep theirs wet. In regard to the other example of a wave line, in the plough, I have only to observe, that for certain practical objects it is an excellent form; it is also theoretically correct on the point of not requiring the expenditure of power to be greater on account of it; but this arises from the fact that the resistance here does not vary with the square of the velocity, but remains constant at all velocities.

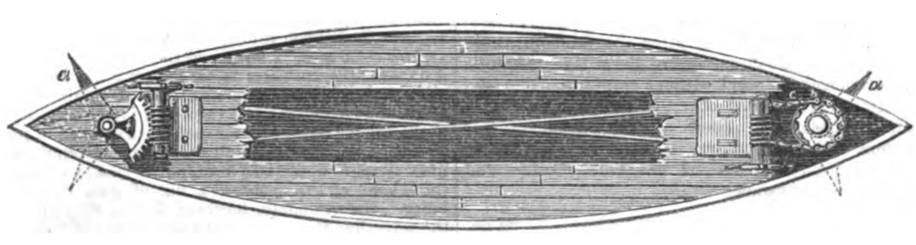
I am, Sir, yours, &c.,

Benj. Cheverton.

August 25.

SHIPS' RUDDERS.

Sir,—Referring to the official trial, by order of the Admiralty, of the plan proposed by Commander Warren, R.N., for steering ships with an auxiliary rudder fixed in the deadwood forward, which, although it



took place under unfavourable circumstances, the result, nevertheless, showed an improvement in steering; but it is not stated how many men were required to work the fore-rudder.

If our Warriors and Black Princes require twelve men to get their stern-rudder over 14 or 15 degrees, it is evident that they would require as many more to hold in the fore-rudder at the same angle, or pull it back against the pressure of water, supposing them constructed on this principle, and the fore equal in power to the stern rudder (which it ought to be)! In this case, a Warrior would require some fifty men with relays to work her rudders! But as our men-of-war require to be turned and manœuvred in as little time as possible to be perfect, why not at once give those which have to be constructed two powerful rudders, one fore and the other aft, and connect them together as in the above diagram? from which it will be seen that the pressure of water coming against the fore-rudder is made available to pull up the aft one, or, in other words, the power to turn a ship in motion is derived from its own momentum! The power of rudders on this principle need not be confined to their present limits, as, however large they are made, an equilibrium is established and a child may work them. But this steering question is one of such vital importance to our navy that it ought not to rest with the best application of the rudder. What is wanted in a man-of-war is a power, not only to turn adroitly when in motion, but when at rest, by two screws properly applied. Depend upon it, Mr. Editor, before long, the neglect of this important matter will necessitate the reconstruction of our navy again, when it will be found that the present form of hull is not adapted to embrace all that is needed. Time, which wears away prejudice, will show the necessity of abandoning the barrel-formed hull, which tumbles and rolls like a porpoise, and topples over when stranded on a beach.

If our Government would try an experiment in steering at a little cost, there are plenty of vessels on the Mersey, the Thames, and elsewhere, that have rudders fore and aft (both ends alike, as I think all ships ought to be built). These ferry-boats are so built to prevent the necessity of turning round, and the rudders are used alternately. Now, if one of these boats had its rudders connected together as I propose, the effect would be seen at once. In the annexed sketch, *a a* are two rudders, on the post of each of which is keyed a ragged wheel B, on which a strong chain C works. Two tension rods or wire ropes *d*, which cross each other in the middle, are attached to the ends of the chains. The strength of the chains and rudders must, of course, be calculated to resist the pressure of the water, which can be done easily. The helms may be actuated in any ordinary manner, but I prefer to work them by worm *e* and sector wheel *f*, as shown. The helmsman may steer from either end of the ship, by throwing the worm at the opposite end of the vessel out of gear. Now, whichever helm is moved (if the ship be in motion), an immense pressure of water comes against the fore-helm, the power derived from which is transmitted through the cross band to pull up the aft-helm, and the ship swings round with great rapidity, consequent on being acted upon at both ends at once, like the head and tail of a fish! When the helms require to be brought back, the pressure on the aft counterbalances that on the fore-helm, and a child's power is sufficient to restore them to the position they were moved from. Theory would indicate that a vessel on this principle might turn round in half the time, but practice, which generally runs panting after theory, in this case outsteps its fantastic companion; as it will be perceived that the rudders may not only be put about instantly, but may be constructed individually of double or treble the power of ordinary ones, the necessary strength of the different parts coming within the province of the engineer.

I am, &c.,

EVAN LEIGH.

Miles Platting Iron Works, Manchester.

RIFLED CAST-IRON ORDNANCE.

SIR,—In your last number you quote the following words from Mr. Britten's pamphlet on rifled cast-iron ordnance:—"In 1860 I was informed by the Secretary of the Ordnance Select Committee at Woolwich, that a recommendation should be made by that body to the War Office, to the end that a gun of strong material should be prepared for the purpose of testing my system, with the muzzle-loading shunt system proposed by Sir W. Armstrong, but, for some reason that I am at a loss to account for, this recommendation was never made." You, on this, remark that Mr. Britten "is 'one more unfortunate' who has had to work out his invention in the face of difficulties and restrictions. He has met," you say, "but small encouragement at the hands of those whose duty it is to examine all plans fairly."

These reflections on the conduct of the Ordnance Committee would be just, if Mr. Britten's statement were true; but his memory has singularly failed him on this subject. Not only did the Committee "recommend" a strong gun to be prepared to test what he calls "his system" with Sir William Armstrong's shunt system, but they carried out the recommendation with two guns, *Mr. Britten superintending the rifling of both, and himself preparing the shells*—68-pound shells, 6½in. in diameter, so as to compare fairly with the Armstrong 70-pound shells of the same diameter. These guns were fired at Shoeburyness on the 18th and 19th February 1861, *Mr. Britten being present.* He desired the charge of powder to be 8 pounds, and his wishes were acceded to. The practice was extremely bad. The fact was that Mr. Britten, so late as 1861, was so utterly ignorant of the laws of motion of projectiles from rifled guns, that he had given to the cannon destined to fire long 68-pound shells only the same spirality of grooving as had proved sufficient to steady the flight of his short 48-pound shells. The consequence was that the long shells were actually less accurate in range than ordinary round shot. If Mr. Britten disputes this, let him publish the exact results of the firing of his shells on the 18th and 19th of February, 1861. You are misinformed, Mr. Editor, on another point. You believe that no cast-iron gun, rifled by Mr. Britten and fired by the Ordnance Committee, "sustained any damage from the operation."

So far from this being the case, a 32-pounder (not bored out even to the size of an ordinary 32-pounder, which is upwards of 6¼in., but only to 5in. diameter) burst with less than forty rounds of only 6½lbs. of powder and 34-pound shells. Mr. Britten has since reduced the charge for 32-pounder guns to 5lbs. Now, as we know them to be safe with 10lbs. and the round shot, it is not astonishing that they do not burst with 5lbs. and a 48-pound shell. The entire expense of Mr. Britten's experiments before the Ordnance Committee has been borne by the country—in all probability 3,000*l*. It is even whispered that he made a profit on the shells which he insisted on supplying himself. It is only fair that he should be informed of this whisper, and have an opportunity of disproving it. When he has done so, and explained his lapses of memory, it will be time enough to begin to consider his startling recommendation—to *increase* the power of our 32-pounder guns by rifling them in such a manner that they can only safely be fired with exactly half as much powder as is now always fired from them; in other words, to arm our ships with 6¼in. cannon to be fired with 5lbs. charges, in order to match them against French ships, which are armed with cannon of the same size, but so strong that their service charge is 16lbs. of powder when firing against ships. A bolt moved through the barrel of a gun by the expansion of the gas of gunpowder is in exactly the same conditions as any other piston moved through any other cylinder by the expansion of any other gas. If, therefore, Mr. Britten can cut grooves in the barrel of a gun, so that 5lbs. of powder shall, in the grooved barrel, produce a greater result than twice as much in the smooth barrel, it is evident that, by grooving the cylinders of all steam-engines in the same manner, the consumption of coal can be diminished by one-half. Let Mr. Britten propose this seriously to some of our mechanical engineers. When he induces one of them to spend 4,000*l*. on experiments, let him blame the Ordnance Committee for only spending 3,000*l*.

I am, your obedient Servant,

ANTI-QUACKERY.

[The letter of "Anti-Quackery" certainly casts a dark shadow over the published facts and figures of Mr. Bashley Britten. We shall be happy, however, to afford the latter gentleman an opportunity of dispelling the clouds which his antagonist has raised, and shall withhold further expression of our own opinion upon the subject until next week.—ED. M. M.]

THE "EXCELSIOR" SEWING MACHINE.

SIR,—Having been accustomed to read with great interest the valuable articles on the International Exhibition which have from time to time appeared in your pages, I was greatly surprised to find the writer of the article on the Processes Court, which appeared in your impression of the 22nd instant, at page 110, has done such manifest injustice to Messrs. Whight & Mann, of Holborn. In reviewing their "Excelsior" sewing machine, the writer, alluding to its peculiar mode of feeding the work along, says, "One can see that this kind of feed can only do with very light work, such as nimble fingers can effect." Now, sir, as one who has been connected, as a practical mechanic, with sewing machines for many years, I beg to state I differ entirely with the writer; but I have seen the "Excelsior" machine used at a high speed on the coarsest materials—such as four thicknesses of stout fustian. I have also seen it sew, with facility, sixteen thicknesses of brown calico. It is also capable of sewing four thicknesses of leather, and from that down to gauze, with almost equal ease.

Having had an "Excelsior" machine in my possession for several months, I know positively what I here state to be matter of fact. Nor is this at all surprising; for one has only to examine the "Excelsior" to arrive at a totally different conclusion from the writer of the article in question. In the first place, the directness with which the moving power is conveyed to the needle gives it a decided superiority in this respect over those machines in which the power is applied at the short end of a lever to overcome resistance at the end of its longer arm. In the "Excelsior" the power is transmitted from the driving wheel along a shaft, from whence it is received by the needle bar, quite close to the bearing of the shaft on the strong iron casting or frame. Again, the needle and needle bar are both straight, and their motion direct. Moreover, the needle does not feed at its point in "penetrating the cloth;" but when it has entered the cloth so as to bring the resistance very near its shank—which is of peculiar size and strength—then it feeds the cloth along; and the thicker the fabric the firmer the hold given to the needle. In fact, I know of no machine having an equal weight or substance of its parts, which is of equal strength, or that will do a greater range of work. As the study of the "Excelsior," from the nice adaptation of its parts, and the beauty of the principles involved in its construction, has afforded me, in common with several mechanical friends, very great pleasure, I trust you will excuse my troubling you with these few observations. As most of the proprietors keep drawings and blocks illustrative of their machines, I shall endeavour to obtain such; and, should you afford me the opportunity, shall attempt further to elucidate the beautiful mechanical principles employed in the "Excelsior."

I am, Sir, yours respectfully,

RICHARD ALLISON, C.E.

8 James Terrace, Leyton Road, Stratford-le-Bow, August 26, 1862.

STEEL SHIPS OF WAR.

SIR,—From your notice of Mr. Bertram's letter, in your number of 15th inst., it may be inferred that I have taken out a patent for my plan of constructing war vessels entirely of armour-plates welded together. This is so far from being the case, that my principal object in writing the letter noticed by "Civilian," and referred to by Mr. Bertram, was to give the idea such publicity in your columns as should for ever prevent the possibility of a patent being subsequently granted for it, and of a great national object being thereby obstructed. The same motive induces me to request you will give publicity to a sister scheme—that of constructing our war ships of steel at a single casting.

I am, Sir, your obedient Servant,

ROBERT AYTOUN.

August 28, 1862.

Gossip.

On September 28, 1836, George Crane, then of the Yniscedywyn (there, you can't pronounce that, dear reader, if you are not Welsh, so we had better tell you it's Enni*sked*win, with the accent on the *ked*) Ironworks, near Swansea, South Wales, patented the use of Neilson's hot blast in connection with anthracite coal. Making iron in those days with any other fuel than charcoal or soft coal was no joke. Mr. Crane got on bravely, however, with anthracite, and the Welsh anthracite — what there is of it — is a fair article. One of the parties who had received a perpetual grant of all the water power on the Lehigh, on the condition of expending 30,000 dols. in building an iron furnace on its bank, came off to England with the intention of looking up Mr. Crane. Accidentally meeting him in London, our friend described to Mr. Crane the capacity and wants of the Lehigh region, and was referred to Mr. David Thomas, who was at that time connected with one of the largest ironworks in South Wales, and who was thoroughly *au-fait* in making anthracite iron. Mr. Thomas, after due negotiation, was engaged as engineer, and some time in 1838 or 1839 he was on his way to the New World. He had ordered two blowing cylinders, 5ft. in diameter and for a 6ft. stroke, to be cast and bored at the Soho Works. These cylinders were duly shipped on board a vessel, which, having had heavy weather on the voyage, put into Norfolk in distress. Had the skipper had tackle sufficiently strong to hoist the cylinders out of the hold of the ship, they would have gone overboard in the middle of the Atlantic. Mr. Thomas, in the meantime, had begun a 12ft. furnace — the first anthracite furnace on the Lehigh, and still in blast — and he could not be kept waiting for the blast tubs, as they had begun to be called. Merrick and Towne, of Philadelphia, were accordingly applied to cast others. But, in the year of grace 1839, the great engineering establishment of the United States could not undertake the casting of a 5ft. cylinder. It was too large a job. There was much delay, but, finally, upon a guarantee to be relieved of all risk of failure, the proprietors of the Southwark Foundry proceeded with the casting, and were successful. The blowing engine was set up, and iron was first cast on July 4, 1840. Thus was started the first furnace of the now prosperous Lehigh Crane Iron Company. The proprietors have built a handsome town at Catasauqua, two miles or so above Allentown. The place now numbers some 2,000 inhabitants; it is supplied with water pumped by steam power, is lighted with gas, and is, altogether, about as attractive and go-ahead a town as can be found, of the same size, in any part of the United States. The Lehigh Crane furnaces at Catasauqua are now five in number, respectively 11ft., 13ft., 16ft., and two of 18ft. diameter. Their total production is 42,000 tons of iron yearly, worth 1,000,000 dols. in New York. There are several other large furnaces in the neighbourhood.

The exportation of iron in its various forms experienced some reduction last year, the total value of the iron and steel sent abroad having been 10,341,574*l*., against 12,154,997*l*. in 1860. There was an increase in pig from 974,065*l*. to 1,047,318*l*.; but bar, bolt, and rod iron declined from 2,385,871*l*. to 1,885,605*l*.; railroad iron, from 3,408,759*l*. to 2,903,357*l*.; cast iron, from 832,638*l*.; wire, from 250,087*l*. to 207,317*l*.; wrought iron of all kinds, from 3,317,349*l*. to 2,868,923*l*.; and unwrought steel, from 986,228*l*. to 727,840*l*. It was in 1853 that the export iron trade assumed its present large proportions, having increased in that year to 10,845,422*l*. as compared with 6,684,276*l*. in 1852, 5,830,370*l*. in 1851, &c. The value of the machinery exported last year was never exceeded in any previous twelve months, steam-engines having figured for 1,243,467*l*., and other kinds of mechanical apparatus for 2,976,221*l*.; while in 1860 the totals were 1,238,333*l*. and 2,599,488*l*. respectively. In 1850 the value of the steam-engines exported was only 423,977*l*., and of the general machinery 618,189*l*.; so that during the last ten or eleven years a vast developement has taken place in the demand for British machinery in foreign countries and in the colonies.

Frequently we hear of the progress of the Suez Canal. We are now informed that Mahomed-Said, the Viceroy of Egypt, has announced that the mingling of the waters of the two oceans shall be inaugurated by a solemn fête, at which the representatives of all nations are to be invited. It must not, however, be forgotten that many of the principal engineers in this and other countries have expressed their serious doubts of the canal ever being cut so that navigation may be effected.

On Thursday last week, says the *Morning Star*, some very interesting proceedings took place at and near Ipswich, that town being visited, at the invitation of Messrs. Ransome & Sims, by a party of 200 foreign noblemen and gentlemen whom the International Exhibition has attracted to London. The object of the meeting was to show the distinguished visitors the perfection attained in the production of agricultural implements at the Orwell Works, and also to illustrate the practical working of reaping machines, steam ploughs, &c. The party, who travelled from town by a special train on the Great Eastern Railway, comprised the Marquis de Perales, and the Marquis de Claramonte, from Spain; the Comte de Fleurien, from France; the Viscount de Villa Maior, from Portugal; Count Trinschietti, from Italy; Mr. J. Robinson, from the Cape of Good Hope; M. Lelong, commissioner from the Belgian Government; the Marquis Pepoli, Italian Minister of Agriculture, and a long list of foreign and colonial gentlemen too numerous to mention. Mr. Alderman Mechi and Mr. Fisher Hobbs were also among the guests. The party were conducted through the Orwell Works in three divisions — the first under the leadership of Mr. J. Head and Mr. J. A. Ransome, while Mr. R. C. Ransome acted as conductor to the second division, and Mr. G. A. Biddell accompanied the remaining section, which consisted of English gentlemen only. After devoting some time to an examination of the numerous interesting processes brought under their notice, the whole party of visitors met in the yard, and were introduced in a short speech from Mr. J. A. Ransome to the 1,200 men employed at the works. Mr. Ransome impressed upon the men how greatly they had profited from the liberal patronage bestowed on the works by many of the visitors present; and the vast body of workmen responded with three hearty cheers, the objects of the ovation seeming well pleased with the compliment. The strangers then set out for Mr. Ransome's Swan's Nest Farm, at Westerfield, near Ipswich, where several illustrations of reaping and ploughing were afforded, the steam ploughing being on the Fowler principle. At five o'clock the whole party assembled, to the number of 300, were entertained at dinner in a tent, Mr. R. Ransome presiding. The speakers on the occasion were — Mr. Alderman Mechi, who, in a characteristic address, enforced the necessity of a liberal application of capital to agricultural operations, in order that the requirements of the increasing population of England might be met; M. Spiers, commissioner from France, who expressed his grateful acknowledgements for the courtesy and hospitality which foreign visitors had received in England during the last few months; the Comte de Fleurien, who, in the French language, stated that he and his compatriots had profoundly admired the reapers of "MM. Burgess et Key," and the ploughs of the "*celèbre* Fowler;" the Marquis de Perales, who proposed "Prosperity to the town of Ipswich," &c. The proceedings were throughout of a very gratifying character.

The *Mining Journal*, in a humorous article on the Patent Office, says, "In the sale department there is a Lord Dundreary diminished, who acts as cashier, and his deputy, two shopmen to wait upon the customers, and two messengers to assist them; and we believe that since the sale of specifications by stamps a seventh assistant has been added to damp the stamps."

A large wrought-iron girder, 74ft. long, 5ft. 8in. high in the centre, and weighing 20 tons, was most successfully removed from Eagle-wharf Road, New North Road, to the Manor Road, Dulwich, by Bray's traction engine, on Friday night. It would have required 25 horses to draw it by the ordinary method. There are many more of these girders to be removed by the same means, they being required to form a bridge at Dulwich, for the London, Chatham, and Dover Railway.

The officers and men of the Royal Engineers at Chatham have been recently occupied in a series of pontooning and diving operations in the Medway, above Rochester bridge, a portion of the river which presents facilities for carrying on operations of this kind. The description of pontoons used on the different occasions of the Royal Engineers being engaged in these duties have been General Blanchard's, in ordinary use by the Sappers and Miners, the newly-invented pontoons by Captain F. Fowke, R.E., the designer of the International Exhibition building, and the ordinary barrel pontoons. The diving apparatus used during the operations was that invented by Mr. Heinké, by the use of which accidents are rendered nearly impossible. At the conclusion of the operations, the pontoon rafts were floated through Rochester bridge to the Pontoon-hard adjoining the Royal Engineers' practising ground.

A Glasgow paper says: — We had the pleasure of witnessing the other day the operation of a new invention for the consumption of smoke, and economising of fuel in furnaces, such as are used in connection with steam boilers, and which has been patented by Messrs. Allan & M'Kiver, of the Hecla Foundry. To consume the smoke a current of intensely heated air enters the furnace, causing combustion of the smoke, which would otherwise escape, effecting thereby an increased production of steam from a given amount of fuel. The tests applied were of the most stringent character, and the results were highly successful. The furnace having been supplied with fresh coal a quantity of smoke issued, such as is emitted from ordinary furnaces, the temporary cover was then removed from the mouth of the patent apparatus, when the smoke diminished, and in less than one minute entirely ceased. The simplicity of the invention is in keeping with the success which has crowned the efforts of the inventors. It must be a gratification to all to know that at last there is a reasonable hope of an end being put to the abominable smoke nuisance, at least in its worst phases, by the use of furnaces on this principle, which is equally applicable to steamers, thus affording, at the same time, a boon to the public in freeing them from the huge volumes of smoke which so often issue from the funnels. It is evident also that this will prove a great advantage to seagoing steamers, seeing that they will require to carry so much less fuel than they, under the present system, are required to do.

The works erected at the breakwater-fort, Plymouth, for constructing the new fort, were destroyed on Monday last. These works consisted of a circle of 170ft. piles with 5ft. iron shoes sunk into the rock round the foundation to form the framework for travelling cranes, by which the blocks of concrete were to be lowered in their places. The works had occupied six months in erection, and were approaching completion. The accident occurred at low water, when about 40ft. of the piles were exposed, and a strong easterly wind was prevailing. The eastern guis and piles first gave way, followed by the whole of the rest, all breaking off at the shoes. The contractors, Messrs. Lee & Son, of London, are said to be heavy losers.

Messrs. Whight & Mann take exception to our description of their sewing machine in last number. Instead of the feed motion being given to the cloth as the needle penetrates it, the revolution of the wheel to which the needle is attached sends it right down before the cloth is moved forward; so that a thick material may be operated on without any risk of breaking the needle.

From the report of the commissioners, issued on Monday, it appears that during the year 1861 3,276 applications were made for provisional protection, 2,047 patents were granted, 2,015 specifications were filed, and 1,229 applications lapsed. The salaries to clerks and officers amounted to 6,573*l*. The fees paid to Sir R. Bethell were 2,238*l*. 12*s*.; to his clerk, 204*l*.; to Sir W. Atherton, as Attorney-General, 2,245*l*. 19*s*.; to his clerk, 203*l*.; to Sir William, as Solicitor-General, 2,320*l*. 10*s*.; to his clerk, 211*l*. 10*s*.; to Sir Roundell Palmer, 2,160*l*. 18*s*.; to his clerk, 195*l*. 15*s*. — total, 9,780*l*. 4*s*. The charge for compensations was 4,584*l*., and for current expenses, 4,153*l*. 18*s*. 1*d*. Printing and stationery cost 16,212*l*. 7*s*. 2*d*.; fuel, 131*l*. 19*s*. 10*d*.; and the Kensington Museum, 1,920*l*. 13*s*. 7*d*. There was thus a surplus income of 36,978*l*. 3*s*. 9*d*., besides a sum of 18,485*l*. for stamp duty.

Mr. Scratchley, the author of the Treatise on Savings' Banks and Banks of Deposit, has issued a proposal for the creation of a "mutual guarantee fund, and for the appointment of a permanent Savings Banks' extension and improvement committee," the object of which is to lay a bill, containing their suggestions and opinions, without delay before the Government in the name of the banks, relative to the creation of a mutual guarantee fund.

It appears an important improvement was introduced during the recent submersion of the additional cable just laid by the Electric and International Telegraph Company from Lowestoft to the Dutch coast. Fishing boats were stationed every five miles to prevent the waste of cable by the "slack" usually attendant on the difficult process of submersion, and a considerable length of wire was thus saved — indeed, it is understood as much as five miles.

A new lighthouse has been placed by the Government of Sweden and Norway in the Gulf of Bothnia. The light will be fixed and visible all round the horizon. There is on board the vessel a large bell, which will be tolled in thick weather.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

Steam Engines, &c., 367, 377, 390.

Boilers and their Furnaces, &c., 365, 384, 391.

Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 380, 393.

Ships and Boats, including their fittings, 372, 373, 382, 383, 397.

Cultivation of the Soil, including agricultural and horticultural implements and machines, 387.

Food and Beverages, including apparatus for preparing food for men and animals, *None.*

Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 363.

Buildings and Building Materials, including sewers, drain-pipes, brick and tile machines, &c. *None.*

Lighting, Heating, and Ventilating, 366, 371, 385, 395.

Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 368, 369, 376, 379, 381, 386, 389, 392, 396, 398, 399.

Metals, including apparatus for their manufacture, 388.

Chemistry and Photography, &c., *None.*

Electrical Apparatus, &c., *None.*

Warfare, &c., 362, 374, 375, 394.

Letter-Press Printing, &c., *None.*

Miscellaneous, 364, 376, 378.

362. F. J. Bolton. *Improvements in rifle and gun stoppers, and oil bottles.* Dated Feb. 11, 1862.

This invention relates to an improved mode of constructing a rifle or gun stopper of a tubular form, so as to combine in one article a gun or rifle stopper, and an oil bottle with pricker or oil pin. The body of the stopper is made of a metal or other tube of suitable length to contain the oil; the brass head which forms the top of the stopper is made flat, and forms also the bottom of the oil bottle. Metallic tubular stoppers have heretofore been covered externally with cork or some other absorbent material, but the patentee proposes to provide these improved stoppers with a casing or covering of felt, woollen cloth, worsted, or other suitable elastic absorbent substance or fabric, which will hold a small quantity of oil. This covering is also made a little larger than the bore of the gun, so as to admit of compression, and, when in the muzzle, will fit quite tight, and fill up the grooves of rifles, and not be liable to fall out when in use. At the other end of the tube is a female screw, into which is screwed the block which carries the pricker or oil pin, consisting of two, three, or more wires, which are secured in the head or top piece. This latter is also provided with a leather washer to prevent the oil from escaping from the bottle, and running down the barrel of the rifle when the stopper is inserted in the muzzle. The head of the stopper being flat and heavy, forms a bottom for the oil bottle to stand upright upon. When the oil pin is screwed into the tubular case or oil bottle, the stopper is complete, and ready to be placed in the muzzle of the gun or rifle, and the worsted covering which surrounds it being of an elastic nature, will fit tightly therein, and will exclude the air and damp, and, being always kept slightly moist with oil, will prevent the muzzle of the rifle from getting rusty. The oil pin consists of several wires coming to one point, and are placed at slight distances from each other, so as to admit of the capillary attraction taking up a small quantity of oil from the bottle, and holding it suspended until it is applied to any part of the rifle which requires oiling. When the stopper is removed from the muzzle of the rifle, as, for instance, when the latter is in use, the stopper is to be kept in a metal sheath, which may be attached by means of a small strap, or in some other convenient manner, to the leather waist-belt, or some other convenient part of the accoutrements. *Patent completed.*

363. J. Herrington. *Improvements in machinery or apparatus for preparing cotton and other fibrous materials for spinning.* Dated Feb. 11, 1862.

The patentee claims: 1. Fluting or corrugating the ends of the beaters of scutching machines. 2. The use of two cranks for actuating the doffer combs of carding engines, one of such cranks being cast upon the shaft. 3. In carding engines he claims mounting those tops or flats which turn upon hinges, and the apparatus for healing, so that they may be moved bodily. 4. In reference to the drawing frame, he claims the application of two trumpets through which the sliver passes, one of them being employed for the stop motion. Lastly, in the drawing frame, the provision for bearing the trumpet lever in an elevated position. *Patent completed.*

364. G. J. Aman. *Transparent envelopes, bags, or wrappers, and appendages thereto, for holding parcels or samples of grain and other dry substances, chiefly applicable for transmission by post at lower rates of postage.* Dated Feb. 12, 1862.

This invention has for its object the means of transmitting through the post office or parcel offices small parcels of, say, grain, or other dry substances, such as mercantile samples, and so forth, by enclosing the same in transparent envelopes, bags, or wrappers made from tracing paper, tracing cloth, book muslin, gauze, bobbin net, or any other suitable and sufficiently transparent substance that will admit of the contents of the parcels being ascertained by seeing them through their enclosure. These improved envelopes or bags intended to hold grain or similar substances, so as to allow the same to be seen at the post office or parcel offices without opening the envelopes or bags, and to allow the envelopes or bags, or appendages thereto, to be stamped without injuring the contents, are made as follows:—The patentee makes part of each envelope or bag to contain the grain or similar substance of transparent calico or similar substance, and another part he flattens so as to provide a suitable surface on which the address is written and the stamp placed, so as to allow the obliteration of the postage-stamps and the impressing of the post-mark thereon by the post-office officials without fear of injury to the sample or other contents of the packet. Or instead of the last-mentioned part, the address and stamp may be carried on a label to be attached by string and eyelets, or by insertion into the mouth of the bag, which is then tied with string or by any other convenient plan, which allows the bag to be separated from the label. *Patent completed.*

365. F. Tolhausen. *A new system of vertical steam boilers.* (A communication.) Dated Feb. 12, 1862.

These vertical steam boilers are constructed with a view to increasing the heating surface, saving of fuel, and consumption of smoke. The main body of these boilers consists of a cylindrical portion of small diameter occupying the centre of the fire-space, under and around it; this vertical cylinder widens out at about two-thirds of the total height of the boiler into another cylindrical and concentric portion, which is firmly united to the said under cylinder by a bottom having the shape of a truncated cone or frustrum. The two cylinders described forming one single recipient contain the necessary quantity of water for generating steam; they are surrounded with and supported by brickwork, but in such a manner as to leave an annular fire-space all round the lower cylinder, and also around part of the upper cylinder. Through the annular space surrounding the lower cylinder, the patentee carries an annular cylindrical and concentric water-chamber, extending from the fire-box to nearly the truncated cone bottom above mentioned, and bisecting the lower annular space vertically. The flames and gases are thus forced to pass up between the inside of the annular water chamber and the small cylinder of the main body, then strike against the truncated cone bottom, pass round the lower portion of the upper cylinder, and finally escape down along the outside of the annular water chamber into flue or flues. By this mode of conducting the combustible gases and other products of combustion, a great saving of fuel and consumption of smoke is effected. The annular water-chamber is in constant communication with the upper portion of the main body of the boiler by means of elbow pipes passing through the annular fire space. *Patent completed.*

366. J. Robb. *Improvements in ventilating.* Dated Feb. 12, 1862.

This invention consists of certain improvements in ventilating churches, dwelling-houses and other buildings, ships, railway and other carriages, and other places requiring ventilation. The principle which the patentee has adopted in carrying these improvements into effect is that of admitting the necessary supply of fresh air at a low level, and carrying off the heated and vitiated air at a higher level, a continuous movement of the atmosphere being thus kept up, while at the same time all disagreeable or hurtful effects from draught are obviated by the peculiar arrangements which are employed for that purpose. *Patent completed.*

367. J. Brickhill. *Improvements in the cylinders and pistons of steam engines.* Dated Feb. 12, 1862.

The patentee claims: 1, supporting the pistons of steam-engines (having horizontal or inclined cylinders) by means of a friction roller mounted in the lower side of the piston, and working on a parallel key or feather placed in the under side of the same, and capable of adjustment by means of a wedge in the manner and for the purposes set forth; 2, he claims the metallic packing-ring in two parts, capable of being adjusted so as to make it fit tighter to the sides of the cylinder, as set forth; 3, he claims the loose tongue or sliding packing-piece working in a groove in the piston, and acting upon the upper surface of the "feather" or key on the cylinder so as to keep the same steam-tight, whether the same is pressed downwards by means of a spring, or acts merely by its own weight, as described. *Patent completed.*

368. T. Coltman. *Improvements in sewing machines.* Dated Feb. 12, 1862.

This invention has for its object to produce a fast or secure stitch, which is not liable to be drawn out, and which is also an elastic stitch, which cannot be broken by pulling or stretching the cloth or work. This is effected by the use of two needles, one placed above and the other below the cloth. These needles are mounted in guides at an angle to each other, and, by means of cranks or excentrics, are made to move up and down, and pass their points through the cloth alternately; and in so doing the upper needle, for instance, when drawn back, will leave a loop through which the lower needle will pass before entering the cloth. This latter in returning also leaves a loop through which the upper needle, in its turn, will pass before entering the cloth, and so on, each needle alternately passing through the loop formed by the other. The cloth or work is moved forward by means of toothed rings or roughened annular surfaces, which are actuated either by pinions or by friction of contact of elastic surfaces. The needles are arranged to work between these toothed rings or roughened annular surfaces, which therefore will bear on each side of the seam, and keep the work straight and steady.) *Patent completed.*

369. A. Hinshaw. *Improvements in hooped skirts.* (A communication.) Dated Feb. 12, 1862.

This invention consists in making the metal hoops of skirts with joints or hinges in such position that, when the skirt is on the wearer, one set of joints or hinges shall come on one side, and the other on the opposite side. The person wearing a hooped skirt having such joints or hinges is enabled to sit down without the skirt and dress worn over it being raised or tilted up in front, or to pass through narrow doorways, enter carriages, or the like, without inconveniently disturbing the set of the dress. *Patent completed.*

370. R. A. Brooman. *Improvements in preparing and ornamenting cast iron and other metals in order to fit them for articles of furniture and decoration and other uses.* (A communication.) Dated Feb. 12, 1862.

The chief object of this invention is to render cast iron suitable for articles of furniture free from all liability to oxidation, and to ornament it by the application of the colouring and decorative processes used to ornament ceramic wares. In order to apply the ornamentation, it is necessary the metal should receive a preparation—that is, it must be covered by a vitrified varnish, upon which the ornamentation or decoration is applied. The inventor obtains this coating in all colours by employing in a dry state opaque enamels in a proper state of fusibility for spreading over the metal, together with colouring oxides used in vitrifiable colours. By this invention imitations of marble, precious stones, and various woods, are among those obtained on cast iron and other metals. *Patent completed.*

371. J. S. Joseph. *Improvements in coke ovens, and in utilising the waste heat from the same.* Dated Feb. 12, 1862.

The patentee claims: 1, the construction of coke-ovens, having external chambers at the top, and flues leading from these and surrounding the sides and bottom of the oven into which the combustible gases enter, and are there caused to undergo more or less complete combustion by being brought into contact with jets of atmospheric air which enter the said external chambers and flues, other jets of air being also caused to enter the ovens themselves for the same object substantially as described. 2, the employment of the spare heat resulting from the above-described combustion of gases in the improved coke ovens, for generating steam in boilers, for making illuminating gas in retorts, for firing pottery, for heating drying stoves, for calcining ores, and for burning lime. *Patent completed.*

372. T. Spencer. *Improvements in propellers for navigable vessels, and engines for actuating the same, parts of which are applicable to other purposes.* Dated Feb. 12, 1862.

This invention consists of a new form of propelling apparatus for navigable vessels, and a peculiar description of rotary steam engine for actuating the same, which engine is also applicable for other purposes, and the propeller may be used as a substitute for the common under-shot water-wheel. The propeller consists of a number of paddle-floats, each formed with three long narrow leaves or feathers, radiating from the longitudinal face of an axle or common centre, and fixed at an angle of 120° to each other. These paddles the patentee mounts loosely on their longitudinal axis parallel to each other, having their bearings at each end supported on two endless chains, which are stretched out in a horizontal direction and work over pulleys. The outer pair of pulleys he mounts in movable bearings, so that the outer or stern end of the apparatus may be lowered down or elevated at pleasure, according to the load draught of the vessel. This propelling apparatus he places in a well or recess formed in the stern of the vessel to which it is applied. The driving power he uses to actuate the propelling apparatus consists of a rotary steam-engine, having a fixed cylinder consisting of a hollow ring, in which revolves one or more pistons on radial arms springing from a centre transverse shaft, having its axis in the centre of the so formed cylinder. The cylinder is fitted with one, two, or more inlet, and one, two, or more outlet valves. He introduces a sliding diaphragm between each inlet and outlet valve, forming surface-pieces dividing the cylinder, and the sides of which act alternately as an abutting surface for the steam, and to divide it from the exhaust. These sliding diaphragms are actuated from the centre shafts by a cam or excentric motion. The engine he connects to the propelling apparatus by a cog-wheel keyed on to the centre shaft, from which the radial arms carrying the pistons spring, and which gears into a second cog-wheel on the shaft containing the two inner pulleys, over which the endless chains carrying the propeller floats work. *Patent completed.*

373. A. Samuelson. *Improvements in building ships and vessels.* Dated Feb. 12, 1862.

The patentee claims the construction of angular ribs or upright frames of plates rivetted to each other and to angle iron, to which ribs or upright frames the outer plating or skin is fixed by rivetting, and to which ribs or upright frames armour-plating, when used, is also fixed by internal flange, as described. *Patent completed.*

374. T. Horsley. *Improvements in breech-loading fire arms.* Dated Feb. 12, 1862.

This invention has for its object improvements in breech-loading fire arms, and is applicable to that class of fire arms in which the breeches of the barrels are opened to receive cartridges by turning the barrels on a horizontal axis at right angles to their length, so as to raise their breech ends up above the breech plate, which closes them when in a position for firing. In order to lock the barrels in such class of fire arms when the breeches are closed, the patentee employs a bolt or catch, which enters a recess in a lump fixed underneath the barrels at their breech ends, and this bolt or catch is connected to a lever placed in front of the trigger guard, and mounted on a horizontal pin or axis, so that by pressing on the lower end of the lever, the bolt or catch may be withdrawn. In order that the pressure may be conveniently applied to the lever, it has a button attached to its end; the stem of the button passes through a slot in the front of the trigger guard, so that the head of the button is within the guard; here it is very conveniently situated for receiving the pressure of the thumb when it is desired to open the breeches, and it is also protected from accidental pressure. The bolt is constantly forced forward by a spring, and it is made to work with an incline, so that in closing the breeches it is self-acting, as when the projection underneath the barrels comes against it, the incline causes it to recede, and as soon as the notch comes opposite to it the spring throws it forward, and causes it to enter the notch. A similar arrangement may be applied to single barrelled guns. *Patent completed.*

375. W. E. Newton. *Improvements in projectiles.* (A communication.) Dated Feb. 13, 1862.

This consists in inserting within the outer periphery of the projectile anti-friction rollers or wheels placed at an angle to the line of motion of the same. These diagonal wheels, by bearing against the inner surface of the barrel, will cause the projectile to rotate on its axis in the same way as the grooves of rifled ordnance act upon their projectiles. At the rear of the projectile, and behind the anti-friction rollers, a packing is adapted to the projectile, and being fitted on a conical seat, this packing will expand and fill the bore of the gun when the explosive force of the powder acts on it behind, and by this means windage is prevented. *Patent abandoned.*

376. J. S. Joseph. *A retort oven and the utilisation of the spare heat from the same.* Dated Feb. 13, 1862.

This consists in constructing a large retort built up of fire-brick, &c., and surrounded by an outer structure of fire-brick in such a way that a space is left all round the retort, the

ends of the same passing through the ends of the enclosing structure, and being provided with suitable doors. To support the retort, the patentee forms piers of fire-brick underneath the same. He prefers to construct the retort of a catenary, parabolic, or elliptic transverse sectional form. This retort or oven he employs for either making coke, charcoal, or for other similar processes wherein combustible gases are disengaged. At or near the top of the retort he forms suitable openings, through which the combustible gases formed inside the same pass into the surrounding space. He introduces small jets of atmospheric air both into the space between the top of the retort and the surface of the materials inside the same, as also into the space surrounding the retort, and thus causes the more or less complete combustion of the gases, thereby creating an intense heat, which, having access to nearly the whole outer surface of the retort, causes the process which is taking place inside the same to be effected in the most rapid and perfect manner. The hot products of this combustion may be rendered available for many purposes. *Patent completed.*

377. J. PETERS. *Improvements in portable steam engines applicable to locomotive, stationary, and marine engines.* Dated Feb. 13, 1862.

In this engine the cylinder is constructed on the oscillating principle, and is placed within the steam of the boiler. The bearings of the trunnions are fixed on the top of the boiler, and the inlet and exhaust passage, as in all cylinders of this construction, are made in the trunnions, one of which is provided with an exhaust pipe and a valve, whereby the action of the engine may be reversed when required. The piston rod is connected to a crank on the end of the crank shaft, which works in steam-tight stuffing boxes, secured to or fixed on the side of the steam dome. The crank shaft carries a band wheel or driving pulley, whereby motion may be transmitted to any machinery that requires to be driven. A force pump for supplying the boiler with water is also mounted on one side of the boiler, and the piston of this pump is worked by an excentric on the crank shaft. *Patent abandoned.*

378. M. A. F. MENNONS. *Improvements in the disinfection of animal excretions, and in the extraction therefrom of fertilising elements for agricultural purposes.* Dated Feb. 13, 1862.

The apparatus for carrying this invention into effect is not described apart from the drawings. *Patent completed.*

379. W. WILLIAMS. *Improvements in pianofortes.* Dated Feb. 13, 1862.

This relates, 1, to horizontal grand pianofortes, and consists in arranging the strings on the sounding board diagonally, that is, inclining towards the right hand in proceeding from the tuning pins to the back. By this means the length of string in proportion to the length of the case is increased, so that, for a given amount of power, the instrument may be shortened, and its form and general appearance improved, or for a given length of instrument the power may be increased. 2, to horizontal pianofortes generally, and consists in arranging the hammers so that they may be caused to strike down upon their respective strings underneath the back parts of the keys, which communicate with the hoppers for working the hammers, thereby increasing the length of vibratory action of the strings, by allowing the bridge on the rest-plank to be placed under the front parts of the keys, and reversing the action of the hammers. The keys, instead of resting on the key-board, are supported on pieces of wood or metal called "key rests," working on wires as centres of motion supported by the key-board. The front end of each "key rest" has a saw cut in it, which admits of the tightness of the key pin being adjusted by a screw, for giving the required freedom to the key, instead of by enlarging the mortice as usual. *Patent completed.*

380. W. HEWITT. *Improvements in rein holders.* Dated Feb. 13, 1862.

This invention is not described apart from the drawings. *Patent completed.*

381. A. C. EBBUTT. *An improved self-adjusting principle to be applied to reclining, easy, or other chairs.* Dated Feb. 13, 1862.

This consists in lowering or altering the inclination of the back and seat by a wood, or wood and metal, frame, to which the back is fastened, being hinged on the bottom frame of the chair, and on which frame, or rollers attached thereto, rests a hinged seat, and by which arrangement, by the action of a person sitting in the chair, the back and seat may be raised or inclined to any desired position, and retained in such position by means of a spring catch and toothed quadrant, which catch is drawn back by handles conveniently placed at the sides or elsewhere. *Patent completed.*

382. W. H. BROWN. *An improvement in yards, fore and aft booms, and gaffs.* Dated Feb. 13, 1862.

This invention in yards consists in forming the central part of yards of metal and tubular, and in inserting arms of wood into the ends of the tubular centre to complete the yard. The invention in booms and gaffs consists in forming the pents near the mast called the jaws of iron with a socket, into which the patentee fits wooden spars to complete the booms and gaffs. *Patent abandoned.*

383. C. D. ABEL. *Improvements in towing boats and other vessels on rivers, and in apparatus employed for that purpose.* (A communication.) Dated Feb. 13, 1862.

This consists in laying an iron chain along the bed of a river to the extent to which it is required to tow vessels, which chain is made to pass up on board a vessel acting as a tug-boat, at one end of the same, whence it passes over guide pulleys to the middle of the vessel, and is there wound several times round one or more drums fixed on a shaft or shafts connected by gearing to a steam engine, or to steam engines fixed in the boat. After leaving the drum or drums before named, the chain is made to pass over guide pulleys along the deck to the other end of the boat, whence it again descends to the bed of the river. *Patent completed.*

384. T. DAVISON. *Improved means for preventing the corroding of steam boilers.* Dated Feb. 13, 1862.

This consists in introducing into the water a salt or salts, such as the carbonate of soda, potash, or lime, capable of neutralising the corrosive action of the injurious agent present in the water. *Patent completed.*

385. F. FALCONER. *Improvements in lamps.* Dated Feb. 13, 1862.

This consists, according to one modification, in combining a glass globe and chimney in one piece, the lower part whereof may be made to resemble any of the ordinary or ornamental forms of globe, whilst the upper part is contracted in diameter and elongated to act as a chimney; or the globe and chimney may be made in separate pieces, being fitted together in any convenient way, but with the chimney portion not reaching lower than the upper part of the globe, or the top of the flame. *Patent abandoned.*

386. J. F. LAWTON and J. LAWTON. '*Improvements in the manufacture of flannel for shirtings and other articles of apparel.* Dated Feb. 13, 1862.

The objects here are to give increased strength and durability to such flannel, and to obviate or prevent the liability of its shrinking in washing, at the same time that the appearance of the material and the brilliancy of the colours are considerably improved. The invention consists in the combination in flannel for such purposes of silk and wool, the combination which the patentees prefer to use being a woollen warp and a silk weft, but other combinations of silk and wool may be substituted with a similar effect. *Patent completed.*

387. R. HORNSBY, Jun. *Improvements in apparatus for thrashing, elevating, cleansing, and separating grain, and in apparatus for elevating straw.* Dated Feb. 13, 1862.

The details of this invention are too voluminous to be quoted here at sufficient length for an intelligible abstract. *Patent completed.*

388. W. D. ALLEN. *Improvements in the manufacture of stamp heads and beds employed in crushing ores and other mineral substances.* Dated Feb. 13, 1862.

This consists in the manufacture of stamp heads and beds, by founding or casting them in molten steel, which, for this purpose, the patentee prefers to use in a hard or highly carbonised state, or to add to the molten steel as much cast or pig iron as will give the degree of hardness required. *Patent completed.*

389. G. C. BURROWS. *Improvements in lounges, seats, or other apparatus for sitting or reclining on, which improvements are also applicable to rocking-horses.* Dated Feb. 13, 1862.

By these improvements a pleasant gravitating, oscillating, adjusting, or rocking motion is obtained. For this purpose the apparatus is formed of one or more triangles, resting each on one line or angle of or between each of such triangles. These lines form fulcra, on which the triangles (which are the legs) may turn, whilst other parts may also rest on the frame of the apparatus, or against each other, and at such point of rest they may be connected by elastic or other suitable means. The parts may also be connected by their opposite upper surfaces. Upon anyone reclining on either end of the apparatus, when made up of more than one triangle, the tendency of such part is to separate from the other end; this tendency is controlled and counteracted by the connections, by which a gravitating, oscillating, or rocking motion is obtained, and which may be assisted by springs. The apparatus may have castors or other wheels, and is applicable to, or in substitution of, rocking-horses. *Patent completed.*

390. E. E. ALLEN and J. STEWART. *Improvements in the construction of steam engines.* Dated Feb. 13, 1862.

This invention is not described apart from the drawings. *Patent completed.*

391. J. E. M'CONNELL. *Improvements in parts of boilers and furnaces for locomotive and other engines.* Dated Feb. 13, 1862.

This consists: 1. In making the upper surfaces of the fire bars of a convex form, in lieu of straight, so as to leave an increased bulk of metal towards the middle of the bar, where the fire acts more fiercely upon it, thus strengthening the bar at the most advantageous part, and still enabling it to be made generally lighter than the ordinary ones. The inventor disposes the bars transversely in the furnace. 2. In lining the tubes of steam generators with zinc, spelter, or other hard metal. *Patent abandoned.*

392. E. GREEN and J. NEWMAN. *Certain improvements in buttons for fastening and ornamenting articles of dress.* Dated Feb. 13, 1862.

This relates, under one modification, to linen buttons, and consists in raising circular or other forms on the front of the button to indicate where the perforations are in the metal forming the bottom of the button. *Patent completed.*

393. J. E. M'CONNELL. *Improvements in railway breaks and in warming railway carriages.* Dated Feb. 13, 1862.

This relates to that system of railway breaks wherein the breaks are applied simultaneously to any or all of the carriages in the train, and consists in the use of a force pump fixed on any convenient part of the train, and worked either by the guard or other person, or by excentrics on the axle of the tender or van, for forcing air or water into a pipe or pipes extending along the entire train, and connected at suitable intervals with horizontal cylinders placed between the pairs of wheels in each carriage, such cylinders having pistons or plungers, which, on being forced outwards by the action of the force pump, will apply the break blocks directly to the wheels or axles simultaneously throughout the whole train. *Patent completed.*

394. A. JANSEN. *A new ball for fire-arms.* Dated Feb. 13, 1862.

This ball is made of lead, and is of a cylindro-conical form. The point or conical part of the projectile is solid, but at the cylindrical part two or more deep grooves are cut round the projectile, leaving corresponding flanges. The point or front end of the projectile will, consequently, be the heaviest, and upon the explosive force of gunpowder acting against the flat rear end, the cylindrical part will be crushed or crowded up against the forward end, and in so doing will be made to expand and fill the bore and grooves of the rifle. *Patent abandoned.*

395. W. G. VALENTIN. *An improved mode of and apparatus for coking coal.* Dated Feb. 13, 1862.

This consists in submitting the coal to the coking operation in a close vessel or retort of a peculiar kind, and also in heating the retort by the combustible gas evolved from the coal during the coking operation. *Patent completed.*

396. S. B. WHITFIELD. *Improvements in the manufacture of iron bedsteads, and in the manufacture of ornamental iron tubes or columns for the construction and ornamentation of iron bedsteads.* Dated Feb. 14, 1862.

This consists in the use of parts made of stamped or pressed iron, the said parts being joined to the other parts by junctions of cast-iron cast in metal moulds, that is, by the process known as chill casting, or by rivetting, or otherwise. The parts which the patentee principally makes of stamped or pressed sheet iron are parts of the pillars and head and foot rails. The manner in which this part of the invention is to be carried into effect may be illustrated with reference to the foot rail of an iron bedstead. *Patent completed.*

397. A. J. DODSON. *An improved composition for coating, covering, or protecting ships' bottoms, applicable also for coating or covering railway sleepers, telegraphic wires, and other surfaces, and likewise as a cement and as a substitute for metal for certain constructive purposes.* Dated Feb. 14, 1862.

This composition is formed by combining pulverised slate with vegetable or mineral pitch. *Patent abandoned.*

398. W. CLARK. *Improvements in mounting and fixing the handles or knobs of doors, furniture, and other articles.* (A communication.) Dated Feb. 14, 1862.

This relates to handles, knobs, &c., formed of glass, crystal, or other fusible siliceous material, and consists in securing the spindle in a recess formed in the interior of such knob, the pin for fastening the knob being carried by the mounting, which affords greater strength and prevents the mounting becoming loose. *Patent abandoned.*

399. T. D. M'FARLANE. *Improvements in sewing machines.* Dated Feb. 14, 1862.

This invention is not described apart from the drawings. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated April 15, 1862.

1090. T. W. Gray, 114 Fenchurch Street. Improvements in the manufacture of explosive compounds. (A communication.)

Dated April 21, 1862.

1153. E. H. C. Monckton, Esq., Thurloe Place, South Kensington. Improvements in the preparation of metal to be used in the construction of cannon, rifles, armour plates, and other objects used in naval or military warfare or otherwise.

Dated April 22, 1862.

1167. E. H. C. Monckton, Esq., Thurloe Place, South Kensington. Improvements in umbrellas, parasols, awnings, tents, and covering cloths, and in waterproofing the same.

Dated April 23, 1862.

1184. A. Hodgkinson, Glenville Bleach Works, Belfast. A mixture of composition to be used in the process of boiling, preparing, or bleaching vegetable substances, whether they are in the manufactured or unmanufactured state, which mixture may also be used in the manufacture of soap.

Dated June 13, 1862.

1766. J. Robinson, Rochdale, timber merchant. Improvements in machinery or apparatus for sawing wood.

Dated June 28, 1862.

1902. J. Petrie, Rochdale, engineer. Improvements in slide valves for steam engines.

Dated July 15, 1862.

2032. E. Draper and E. Thomas, Birmingham. A new or improved method of strengthening wooden shutters and doors.

Dated July 18, 1862.

2051. J. Willcock, 89 Chancery Lane, consulting engineer. A new ornamental fabric, and the machinery for producing the same. (A communication.)

2053. F. L. Stott, Rochdale, machine maker. Improvements applicable to mechanism or apparatus for warping yarns or threads.

Dated July 22, 1862.

2083. R. Grogan, 22 Westbourne Gardens, Bayswater. Improvements in screw propellers of steam vessels, and in the arrangement thereof.

Dated July 23, 1862.

2093. C. J. Keene, 10 Shrewsbury Villas, Bayswater. A new or improved winding apparatus for raising and lowering canvass on easels.

2095. E. K. Dutton, Stretford, Lancashire, mechanical draughtsman. Certain improvements in steam engines.

2097. W. Clark, 53 Chancery Lane, engineer. Improvements in the manufacture of manure. (A communication.)

2099. R. Bell, Esq., Westland Row, Dublin. Improvements in the manufacture of bricks. (A communication.)

Dated July 24, 1862.

2101. J. Dickson, 66 Tollington Road, Holloway, gentleman. Improvements in treating copper ores and solutions of copper to obtain copper therefrom.

2103. W. Clissold, Dudbridge, Gloucestershire, engineer. An improved mode of manufacturing cylinders.

2105. T. Lemaistre, 3 Rue de Grammont, Paris, architect. Improvements in privies.

2107. W. H. Perkin, Seymour Villa, Sudbury. Improvements in printing and dyeing when aniline and analogous coal-tar dyes are employed, also in preparing colouring matters. (A communication.)

Dated July 25, 1862.

2111. J. Redgate, Sneinton, Nottinghamshire, lace manufacturer, and H. Redgate, Stoney Street, Nottingham, lace manufacturer. Improvements in machinery or apparatus for the manufacture of fabrics on bobbin net or twist lace machines.

2113. P. Robertson, Glasgow, merchant. Improvements in producing brushing or frictional surfaces.

2115. J. Seymour, Queenstown, wine and spirit merchant, and D. G. Hatcher, Southampton, yacht builder. Improvements in steering ships and in apparatus for the same.

2117. V. Manzini, Modena, Italy, engineer. Certain improvements in the construction of locomotive engines used on railways for facilitating and controlling the ascent and descent of locomotive engines and trains on inclined planes of lines of railway, and for simplifying the construction of locomotives used on railways.

2119. A. Lahousse, Lupus Street, Pimlico, mechanician. An improved construction of railway wheel.

Dated July 26, 1862.

2121. T. Sagar, machinist, and J. Rocliff, Burnley, Lancashire, moulder. Improvements in moulding.

2123. W. Clark, 53 Chancery Lane, engineer. Improvements in obtaining or extracting silver from ores and other bodies, and in apparatus for the same. (A communication.)

2125. T. Long, 2 Clarendon Place, Notting Hill, house decorator. Improvements in the manufacture of open metal work, applicable to various useful purposes.

Dated July 28, 1862.

2130. W. Spence, 50 Chancery Lane. Improvements in the preparation of a red colouring matter. (A communication.)

2131. P. S. Devlan, Commercial Foundry, Commercial Street, Manchester, engineer. Certain improvements in the manufacture of telegraphic cables.

2132. W. Spence, 50 Chancery Lane. Improvements in the preparation of a blue colouring matter. (A communication.)

2135. T. Cook, Manor Place, Walworth, machinist. Improvements in apparatus employed in the manufacture of envelopes.

2137. J. Fourdrinier, Grove Terrace, Peckham, gentleman. Improvements in apparatus for removing knots from pulp.

2139. F. Selby, Surbiton, Surrey, engineer. Improvements in surface condensers.

2141. E. Burnett, Ashford, Kent, coach builder. An improved combined cart and sleigh.

2143. C. W. Siemens, 3 Great George Street, Westminster. Improvements in gas engines.

Dated July 29, 1862.

2145. Z. Colburn, 15 Tavistock Street, Bedford Square, mechanical engineer. Improvements in steam pumping engines.

2147. A. Boyle, Birmingham, tool maker, and T. Warwick, Birmingham, machinist. Improvements in the manufacture f the ribs and stretchers of umbrellas and parasols and in machinery to be employed in the said manufacture.

2149. P. S. Devlan, Commercial Foundry, Commercial Street, Manchester, engineer. An improved composition to be employed for covering projectiles and the internal and external surfaces of vessels, which is also applicable to the manufacture of tubing and to other useful and ornamental purposes.

2151. C. T. Burgess, Brentford, Essex, engineer. An improved stand for beer and other casks.

2153. J. Mapple, 2 Newman's Place, Kentish Town, and D. Mapple, 3 Queen's Road, Homerton New Town, telegraph and clock makers. Improvements in telegraphic apparatus.

2155. M. Henry, 84 Fleet Street. Improvements in obtaining fibrous materials and paper pulp, in treating, cleansing, and scouring fibrous materials and fabrics manufactured thereof, in producing soap for the said operations, and in obtaining products from liquors used therein. (A communication.)

Dated July 30, 1862.

2159. J. Hyde and J. Hyde, Bradbury, engineers. Certain improvements in governors for steam engines, water wheels, mills, and for other similar purposes.

2163. J. Benyon, Swinton, manager. Certain improvements in looms for weaving.

2165. W. Clark, 53 Chancery Lane, engineer. Improvements in gas burners. (A communication.)

2169. J. W. Woodford, Sutherland Street, Walworth. Improvements in machinery for raising or forcing water.

Dated July 31, 1862.

2171. W. Weild, Manchester, engineer. Improvements in machines for cutting, shaping, rolling, drilling, screwing, milling, and fluting metals.

2173. C. Bedells, Leicester. Improvements in the manufacture of braces.

2175. A. V. Newton, 66 Chancery Lane, mechanical draughtsman. Improved machinery for planing metal. (A communication.)

Dated August 1, 1862.

2177. J. List, Carisbrooke. An improved means of and instruments for obtaining distances and heights, and distances between distant objects, without computation.

2179. D. T Lee, Birmingham, manufacturer. An improvement or improvements in ornamenting surfaces of wood and of papier mâché.

2181. G. A. Biddell, Ipswich, mechanical engineer. Improvements in railway crossings.

2187. T. G. Webb, Manchester, glass manufacturer. Improvements in the manufacture of flint glass.

Dated August 2, 1862.

2189. J. Briggs, Blackley, Lancashire, engraver and manufacturer. Improvements in the manufacture of belts, webs, braids, tapes, laces, and other similar articles produced by weaving, plaiting, or twisting.

2193. G. Coles, Gresham Street West, merchant, and J. A. Jaques, chemist, and J. A. Fanshawe, engineer, Tottenham. Improvements in the manufacture of grinding and polishing tools and surfaces.

Dated August 4, 1862.

2194. A. & E. M. Denny, Waterford, Ireland, merchants. Improvements in the manufacture of bacon.

Dated August 5, 1862.

2195. S. Simon, Tuilerie Street, Hackney Road. An improvement in ornamenting ladies' and children's slippers.

2198. J. Townsend, Glasgow, manufacturing chemist. Improvements in damping cotton and other fibrous materials and fabrics, in preserving the same from mildew, and in preserving size or stiffening from decomposition.

2199. W. Clark, 53 Chancery Lane, engineer. Improvements in the purification of water and in apparatus employed therein. (A communication.)

2201. J. R. Nicholl, Streatham, Surrey, clerk. Improved means of, and apparatus for, utilising and disposing of the sewage of towns and villages.

Dated August 6, 1862.

2203. W. W. Burdon, Esq., Newcastle-upon-Tyne. Improvements in reducing wood fibres to pulp.

2205. M. C. Sinibaldi, 1 South Villas, South Street, Greenwich. Improvements in the manufacture of chains, and in the apparatus employed therein.

2207. F. Nauheim, Cecil Street, Mile End Road, boot maker. An improvement in the ornamenting of boots, shoes, and goloshes.

Dated August 8, 1862.

2222. J. Whipp, Rochdale, jeweller. An improved arrangement of apparatus and means for cleaning articles of ornament and jewellery.

2224. R. A. Brooman, 166 Fleet Street, patent agent. Improvements in repeating firearms. (A communication.)

2226. E. Humphrys, Deptford, engineer. Improvements in steam engines.

Dated August 9, 1862.

2230. G. Haseltine, 100 Fleet Street, American barrister-at-law. Improvements in carriage wheels. (A communication.)

2234. A. J. Moreau, chymist, and A. E. Ragon, gentleman, Bernard Street, Russell Square. Improvements in the manufacture of gas and coke.

Dated August 11, 1862.

2238. H. Fenton, Queen's Ferry, Lancashire, wire drawer and wire rope manufacturer, and W. Stubbs, Liverpool. Improvements in telegraph wires.

2240. J. Goodfellow, Blackburn, engineer. Improvements in steam or water engines.

2242. W. Clark, 53 Chancery Lane, engineer. An improved carriage for conveying sugar moulds in sugar refineries. (A communication.)

2246. W. E. Gedge, 11 Wellington Street, Strand. Improvements in the construction of ladders. (A communication.)

2248. H. Donald, Renfrew, engineer. Improvements in machinery for shearing, punching, and riveting metals.

2250. R. Gresty, Packington Street, Islington. Improvements in scarfs or cravats.

Dated August 12, 1862.

2254. J. Dickson, 66 Tollington Road, Holloway, Middlesex, gentleman. Improvements in treating ores and solutions of lead to obtain lead therefrom.

2258. C. M. Westmacott, 42 Noble Street. Improvements in cements.

2262. C. Sengry, 54 Great Queen Street, Lincoln's Inn Fields, manufacturer and importer. An improved smoking pipe, which may also be adapted as a tube for smoking cigars.

2264. J. Bower, Carlow. Improvements in railway sleepers.

Dated August 13, 1862.

2266. J. Dickson, 66 Tollington Road, Holloway, Middlesex, gentleman. Improvements in obtaining sodium from certain sources of that metal.

2270. C. W. Smith, W. Mould, Belmont, S. Cook, and W. H. Hacking, Bury, machinists. Improvements in looms for weaving.

2272. J. Peters, Wouldham Hall, Rochester. An improved hydraulic cement.

2274. G. Turner, Woolwich Dockyard, master shipwright. Improvements in fastening armour plates of ships.

2276. L. Galli, Lucca, Tuscany. Improvements in apparatus for propelling vessels.

2278. J. H. Johnson, 47 Lincoln's Inn Fields, gentleman. Improvements in carts and other vehicles. (A communication.)

Dated August 14, 1862.

2282. J. Key and E. Hoskins, Birmingham, metallic bedstead manufacturers. An improvement or improvements in the manufacture of plain and ornamental metallic pillars for bedsteads, cots, couches, tables, and other like purposes.

2284. C. E. Wilson, Monkwell Street, manufacturer. An improvement in buckle fastenings for braces and belts.

2288. H. R. Passey and L. Niman, 17 Little Newport Street, Leicester Square. An improved cigar tube or holder.

2290. W. J. Curtis, Tuffnell Park Road, Holloway. An improved mode of, and apparatus for, ascertaining the fares and earnings of public vehicles.

2294. W. B. Herapath, 32 Old Market Street, Bristol, physician and consulting chemist. Improvements in decolorising solutions of sugar, and also vegetable juices containing sugar.

2296. W. B. Herapath, 32 Old Market Street, Bristol, physician and consulting chemist. Improvements in treating crystallisable sugar to render it more suitable for fermentation and conversion into alcohol and vinegar.

Dated August 15, 1862.

2302. T. F. Kirby, Aldersgate Street, merchant tailor. Improvements in garments for gentlemen and ladies' wear.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

2298. M. A. F. Mennons, 24 Rue du Mont Thabor, Paris. An improved apparatus for the production of sealing wax impressions. (A communication.) *Dated August 15, 1862.*

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

1080. T. H. Bennett. Manufacture of hats.
1085. G. Bedson. Manufacture of wire ropes.
1090. T. W. Gray. Manufacture of explosive compounds. (A communication.)
1096. T. Edwards and J. Harrison. Letter receiving boxes.
1100. D. Stott. Manufacture of rings from paper, millboard, or pasteboard.
1106. W. J. Marsden. Eye-shades.
1120. W. Harling, J. M. Todd, and T. Harling. Looms.
1125. J. L. Perin. Machinery for mortising wood.
1136. R. Dennison. Reaping and mowing machines.
1142. B. Rhodes. Manufacture of cylinders, tubes, and other vessels from paper.
1150. H. Lumley. Rudder.
1159. R. A. Brooman. Jackets or protectors for covering metal and other surfaces to prevent loss of heat by radiation. (A communication.)
1161. T. Attwood. Kitcheners.
1167. E. H. C. Monckton. Umbrellas and parasols.
1174. R. Boby. Rolling or crushing land.
1184. A. Hodgkinson. A mixture of composition to be used in the process of boiling, preparing, or bleaching vegetable substances.
1186. G. T. Bousfield. Elliptic springs for wheel carriages and other purposes. (A communication.)
1188. W. E. Newton. Fertilising composition. (A communication.)
1201. F. Dangerfield. Lithographic or zincographic presses.
1202. R. Mushet. Lining, repairing, or "fettling" of puddling furnaces.
1203. J. Offord. Carriages.
1221. W. Fisken. Cultivating land by means of steam power.
1229. E. Alcan. Carding engines. (A communication.)
1243. R. Vaile. Propellers.
1253. J. Ross. Grinding stones. (A communication.)
1262. W. E. Newton. Mowing and reaping machines. (A communication).
1263. M. Henry. Aerating liquids. (A communication.)
1289. C. P. A. Douchairn. Apparatus for letting in or shutting off water or other liquids.
1373. J. M'Can. Drying, cooling, and cleaning grain.
1376. W. Riddle. Hydraulic and other presses.
1414. H. W. Sambridge. Sliding chandeliers, gasaliers, and other pendent lamps.
1506. F. E. Sickels. Steering vessels.
1507. J. C. Gore. Belt shippers.
1529. H. B. Barlow. Presses for cotton. (A communication.)
1606. R. A. Brooman. Manufacture of looped or knitted fabrics. (A communication.)
1699. P. M. Parsons. Ordnance.
2039. W. Henson and W. W. Clay. Knitting machinery.
2057. C. A. Day and T. Summers. Sheer legs.
2078. S. & J. Lord. Carding engines.
2093. C. J. Keene. Winding apparatus.
2097. W. Clark. Manufacture of manure. (A communication.)
2105. T. Lemaistre. Privies.
2111. J. & H. Redgate. Manufacture of fabrics.
2113. P. Robertson. Producing brushing or frictional surfaces.
2162. W. Wanklyn. Opening and conditioning tightly compressed cottons.
2189. J. Briggs. Manufacture of belts.
2226. E. Humphrys. Steam engines.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed August 22, 1862.

471. W. H. Ross.
472. J. Kirkwood.
473. A. Bornemann.
476. C. H. J. W. M. Liebmann.
480. G. Blakey, S. Blakey, J. Blakey, and B. White.
482. R. Foster.
485. W. Johnston.
488. J. C. Haddan.
489. R. Waller.
495. L. Davis and F. M. Parkes.
497. F. St. G. Smith.
502. J. Piddington.
504. E. Bliss and H. Lamplough.
506. T. Watson and R. Dracup.
512. C. Kingsford.
514. H. W. Cook.
516. A. Green.
517. A. Stephen.
523. T. King and R. Varvill.
524. J. Cliff.
526. C. L. Knoll.
529. W. P. Savage.
530. J. Medhurst.
531. J. Smith.
532. G. Torr.
533. T. Adams.
536. W. Smith.
538. Sir C. T. Bright.
541. J. R. Foster.
542. W. S. Wood.
543. J. Revell.
544. P. D. Azemar.
545. W. H. Muntz.
546. A. W. Makinson and W. F. Batho.
552. J. Parker.
554. T. Bradford.
682. L. Vidie.
690. S. V. Bonneterre, C. T. Erhart, and J. F. Monti.
744. T. Myers.
863. W. A. Ashe.
866. E. T. Noualhier.
957. L. Lindley and F. Taylor.
1020. E. Funnell.
1084. A. V. Newton.
1124. G. T. Bousfield.
1189. W. E. Newton.
1231. S. & G. Cheavin.
1248. J. E. A. Gwynne.
1610. J. Critchley.
1618. R. Griffiths.
1733. J. G. Appold.
1850. J. Taylor.
1886. J. Lord and J. Brown.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

1905. W. T Henley.
1914. G. W. Petter and T. D. Galpin.
1915. W. A. Vérel.
1944. M. J. Stark.
1917. J. J. O. Taylor.
1970. J. H. Johnson.
1958. E. Rettig.
1933. J. Henry and J. E. H. Andrew.
1950. C. Hanson.

PATENTS ON WHICH THE SEVENTH YEAR'S STAMP DUTY HAS BEEN PAID.

1877. A. Savage.
1921. C. Schlickeysen.

Note.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, SEPTEMBER 5, 1862.

THE INTERNATIONAL EXHIBITION.

Iron, Hardware, &c.

Among the treasures of the Eastern Transept it would be unfair to omit noticing one of the most conspicuous, and, in some senses, one of the most important, trophies, namely, that of Mr. Bessemer. The taste which induced that gentleman to select as the medium for exhibiting specimens of his iron and steel, a polished mahogany stand, more in keeping with the fitments of a modern gin palace than appropriate to the use to which it is applied, may be questioned; but there can be no question about the value of the materials which the stand serves to display. In every variety of form, and in every process of its manufacture, the Bessemer iron and steel are shown in the Eastern Transept, and their adaptability to innumerable purposes is developed. It is not necessary here to enumerate the articles exhibited, nor to enter into the particulars of the remarkable and yet simple processes by which the conversion of crude iron into steel of the Bessemer kind is effected. It may be stated, nevertheless, that many and severe were the testings to which the substance was exposed, before it was admitted into the favour of those who were predisposed to the use of steel produced by the old, and time-honoured system. The extreme toughness of the Bessemer iron was proved by the bending of a cold bar of 3in. square, under the hammer, and into a close fold, without the smallest perceptible rupture of the metal at any part; and the bar was thus extended on the outside of the bend from 12in. to 16¼in., and was pressed on the inside from 12in. to 7¼in., thus showing a difference in length of 9½in. between what, before bending, were the two parallel sides of a bar 3in. square. Again, an iron cable, consisting of four strands of round iron 1½in. in diameter, was, while cold, so closely twisted as to cause the strands at the point of contact to become permanently embedded into each other. Each of these strands had become elongated to 12½in. in a length of 4ft., and had diminished one-tenth of an inch in diameter throughout their whole length.

Steel bars, of 2in. square and 2ft. 6in. in length, were twisted cold into a spiral, the angles of which were about 45°; and some round bars, 2in. in diameter, were bent cold under the hammer, into the form of an ordinary horse-shoe magnet, the outside of the bend measuring 5in. more than the inside. The steel and iron boiler plates, left without shearing, and with their ends bent over cold, afforded ample evidence, too, of the extreme tenacity and toughness of the metal; while the clear, even surface of railway axles and pieces of malleable iron ordnance, were examples of the perfect freedom from cracks, flaws, or hard veins. The tensile strength of this metal was not less remarkable. The several samples of steel tested in the Proving Machine at Woolwich Arsenal bore, according to the reports of Colonel Eardley Wilmot, R.A., a strain varying from 150,000lbs. to 160,900lbs. on the square inch. Four samples of iron boiler-plate similarly tested, bore from 68,314lbs. to 73,100lbs.; while, according to the published experiments of Mr. W. Fairbairn, Staffordshire plates bore only 45,000lbs., and Low Moor and Bowling plates a mean of 57,120lbs. per square inch. Of course, the cost of production of the materials was considerably less than that of the plates put into competition with Mr. Bessemer's; and here another advantage of no slight consequence is evident.

Leaving now the Bessemer stand, or trophy, let us enter what is known as the South Court, and which extends westward from the Eastern Transept, nearly to the Central Avenue. Here, indeed, is a perfect *embarras du richesse* in the way of iron and hardware, and the difficulty is where to commence our notice of the principal gems in detail. In the way of ecclesiastical wrought metal work, the new rood screen for Hereford Cathedral, designed by Mr. G. G. Scott, R.A., and executed by the Skidmore Art Manufactures Company strikes the eye. It consists of an open arcade of five arches, each of which is divided by a central shaft, whilst the head of the arch is filled by geometrical tracery. It is an elegant work, alike creditable to the taste and skill of the designer, and to the workmanship of the company to whom its execution was intrusted. The judicious combination of polished brass and wrought iron work produces a highly contrasted and yet harmonious effect. Such structures, indeed, go to prove that Art is revivifying amongst us, and form a counterpoise to some abortions which might be named, and in which realisation has by no means justified conception. The Norwich gates, and those of the Coalbrookdale Company, are both excellent specimens of workmanship; but as they have already obtained, on all sides, a fair modicum of admiring criticism, we leave them for the present, and turn to subjects of a less striking and grand, but not less useful character. Of these, as we have seen, there is abundance. We pass on through the Sheffield Court, wherein Messrs. Cammel, Messrs. Rodgers, Turton & Sons, Turton Brothers, and sundry firms of nearly equal eminence, are great in the cutlery and edge tool way, and reaching the Wolverhampton Court, are attracted by the show of Messrs. Lambert & Sons, of Walsall, Staffordshire, and Lambeth. Although the actual display made by this well-known house is not so meretricious as some of those in its immediate neighbourhood, yet it speaks eloquently of the nature of the works, in which they excel. The Messrs. Lambert are, indeed, justly celebrated for their contributions to what may be termed sanitary engineering. Almost every appliance of a mechanical nature which can be conceived in reference to this important branch of the engineer's occupation has, apparently, been produced by this firm. To catalogue them all would, indeed, be an impossibility.

The high-pressure valve cocks manufactured by Lambert & Sons are especially valued on account of their simplicity, durability, and cheapness. In almost all cities and towns at home, where the constant-supply system prevails, these are used, and so they are at Amsterdam, Copenhagen, Bombay, and other cities abroad. In the way of cast-iron sluice valves or main cocks, few manufacturers are able to excel those in question, and that known as the "improved sluice or steam valve" (Underhay's patent) is remarkable for its efficiency and usefulness. The novelty in the construction of this valve consists in the introduction of loose-faced plates with an elastic substance behind them, and the main advantages gained by it are:—1st, that perfect contact between the slide and gun-metal fans is secured under all circumstances. 2nd, that the faces may be taken out for repair without removing the body of the valve or breaking the joints. 3rd, that the cup with screw, nut, and stuffing-box, can all be removed for cleaning or repair, leaving the slide closed. This renders the shutting of any other valves on the main unnecessary. In fact, this valve does seem to be free almost from imperfection, and its inventor is entitled to a considerable amount of praise for having designed so thoroughly practical a contrivance. In the way of pumps and hydraulic apparatus, the Messrs. Lambert are well represented at the Exhibition, and so they are in respect to locomotive boiler tubes, wrought-iron tubes for general purposes, steam cocks, &c.

Before leaving the Wolverhampton division of the South Court, it may not be unadvisable to look at what has been done since 1851 in the matter of fire-proof safes; and conspicuous in this branch are several admirable specimens shown by Mr. Price, who, by the way, makes, in his published circular, some very sensible and truthful remarks on the subject. That gentleman states, that "at the period of the "former Exhibition few real improvements "in the construction of iron safes and locks "had been introduced, and, as a consequence, "there was little deserving of commendation "in the former class, whilst in the latter the "best locks of the most eminent makers were "openly picked with ease. No medal was "awarded for iron safes, and in the Gilbart "Prize Essay on practical banking, Mr. Granville Sharp, in his article on safes, says:— "'It must, however, be observed that the "'safes of the Great Exhibition (of 1851), as "'a whole, are distinguished rather by orna- "'ment and beautiful workmanship than by "'strength and practical utility for banking "'purposes; they are too small, too handsome, "'and too costly.'"

Mr. Price appears to have profited by the shortcomings of 1851, and in 1862 he has been fortunate enough to have awarded to him a medal for safes and locks. Mr. E. B. Denison, no mean authority on the subject of locks and safes, had previously expressed a very high opinion of those of Mr. Price, and pointed out the practical points of superiority by which he considered them distinguished.

Messrs. Bramah, Hobbs, Ashley, & Co., and Mr. Chubb, are the other leviathans in the lock and safe department of the International Show, and they well sustain the reputation they had, long previous to its opening, achieved.

The number of Birmingham exhibitors in the South Court is prodigious, and the variety of articles exhibited by them interminable. Certainly, if *excess* of human ingenuity be a possibility, the Birmingham exhibitors possess it. Nothing is above or below the reach of their inventive minds, and their skilful fingers realise with marvellous effect the conceptions of their active brains. If we were but to commence an enumeration of the products of their mechanical talent, we should not know when or where to put a period to it. It is necessary, however, to think of bringing our remarks upon iron and hardware to a conclusion for this week, and this we will do by a quotation from the poetical (?) circular of one of the exhibitors in the South Court. It has been our fate to meet occasionally with some strange productions of the poetic muse, but never, we believe, with anything so outrageous as the following:—

And now the Anthems of the wondering bard
Swell o'er the name of W. Poupard.
'Neath a bushel long was light of Science hid,
But now the world-famed Patent Safety Skid
Sheds the bright radiance far abroad,
From 257 Blackfriars Road. (!)

We forbear to transcribe more of this wondrous effusion, lest the consequences to our readers might be serious, and we seriously advise "W. Poupard," in mercy, to stay the distribution of such nonsense.

The skid referred to appears to be well adapted for its purpose, and its proprietor might allow it to rest upon its own merits rather than make himself ridiculous by the publication of such trash as the above.

Mr. Poupard, in addition to his "World-"famed Patent Safety Skid," is, it appears, also the proprietor of the "Patent Curvilinear Beam "and Paracentrical Wharf Machine," whatever that may be.

NEW COINAGE FOR HONG-KONG.

We learn with much satisfaction that it is the intention of the British Government to cause a new and distinctive coinage to be struck for the flourishing, and populous colony of Hong-Kong. The metallic currency of that place has hitherto consisted of as strange and heterogeneous a collection of coins as could possibly be imagined, and the confusion and mystification arising from this state of things are intolerable in the highest degree. Spanish and Mexican dollars are intermingled with pieces of money from almost every part of the world, and the miserable specimens of Chinese mintage, known as "cash," serve to make the jumble more complete. It is in consequence of strong representations from the colonial authorities at Hong-Kong of the evils and annoyances arising from this serious defect in the currency, that the Home Government has determined to remodel it. Much care will have to be exercised, no doubt, in the introduction of a new coinage, because a very large proportion of the inhabitants consists of Chinese, and their habits and prejudices must, to a certain extent, be respected. It will not be possible to wean the "Celestials" all at once from their ancient notions of monetary matters, or to familiarise them easily with our own views of pounds, shillings, and pence. Any transition, indeed, will have to be made gradually, and without shock to the feelings of John Chinaman. We believe that the Duke of Newcastle, in his official capacity of Colonial Secretary, has fully considered the difficulties which will have to be surmounted in effecting the proposed change, and the plan of operations proposed by him seems to be well calculated for overcoming the practical and moral obstacles in its way.

It is intended that the dollar shall for the present remain the unit of value, and that the new coins shall comprise divisions of that unit. The subsidiary coins will be named, respectively, ten-cent pieces, which will be of silver, one-cent pieces, of bronze, and, for the purpose of humouring the Chinese, British "cash" pieces, or mils, which will be composed of copper. The first-named coin of the series will be equal in value to the half-franc of the French Empire; the second to the cent of America; and the third, or British cash, will be equal in value to the one-thousandth part of the dollar. It may seem strange that coins of so small a value as this last—less, indeed, than the fourth of a farthing—should seem necessary; but the innumerable variety of articles which, in the markets, shops, and street stalls of Hong-Kong, are fixed at the price of a single cash, is at once a justification of this proceeding, and a proof of its necessity. The last census of the colony demonstrated the fact that there were 120,000 Chinese resident in it, and as these from their childhood have been accustomed to the use of the "cash," it has been deemed prudent to supersede the rough native coin of that name by a well finished and handsome specimen of English mintage. The preservation of the name will, it is hoped, reconcile the Chinese to the modification. It is, perhaps, scarcely essential to inform our readers that the "cash" of the "Celestial" empire is simply a thin disc of gun-metal, ornamented by hieroglyphics, which has been cast in moulds—not struck from dies—and having a small square hole through its centre. The diameter of the cash, and its weight, have been varied by different Emperors, as have the Chinese characters which are supposed to decorate it. These inequalities have not lessened the annoyances arising from the mixture of coins circulating at Hong-Kong.

In the proposed new British "cash" there will, of course, be uniformity of size, weight, and diameter. The hole through the centre of the coin will be retained, as almost all Chinamen prefer stringing their money like beads round their necks, to carrying it like "outer barbarians," in their pockets. The hole, however, will be a round one, of about an eighth of an inch in diameter, and whether this arrangement will square with the views of our pig-tailed friends remains to be discovered. It certainly will prevent the coin bearing the image of Queen Victoria, although its being a round hole instead of a square one will obviously facilitate the process of coining the British cash pieces at the Mint. The designs for the new cash pieces are simple but not inelegant. On what may be termed the obverse side there will appear the words, in English, Hong-Kong, One Cash, with the date 1862; on the reverse the same inscription will be given in Chinese characters. The first instalment of British cash transmitted to the colony will comprise, we are told, no less than twenty millions of coins.

As regards the ten-cent pieces, they will be slightly smaller in size than the sixpence. The obverse will exhibit the profile of Her Majesty, with a suitable superscription, and the reverse will consist of a wreath enclosing the words Ten Cents, Hong-Kong, and the date 1862. The devices ornamenting the one-cent bronze piece will resemble those on the cash, and like that piece it will be perforated for doing duty as part of a necklace. The first coinages of ten-cent and one-cent pieces will consist, respectively, of 100,000 and 1,000,000 coins. It is presumed that the introduction of the three varieties of coin named will be attended with some little trouble, but a Royal Proclamation legalising them, carefully drawn up both in the English and Chinese languages, and widely published throughout the island of Hong-Kong, will smooth the way and lighten the labours of the Governor in accomplishing the praiseworthy task.

That the Chinese are not unwilling to adopt new systems which commend themselves to their good sense has been clearly demonstrated in the colony by their patronage of the Chartered Banks established there. The notes issued by those banks are taken without hesitation, and indeed are cashed freely in the province of Kwang-tung, seventy or eighty miles above Canton, by native bankers, and at a charge of not more than one-tenth per cent. This at least is a hopeful sign, and it leads to the supposition that, in due time, other reforms may be accepted by the Chinese, provided they be instituted and carried out in good faith, and with a proper deference for their time-honoured, though rather exceptional, manners and customs. It is probable, indeed, that the British Government will gain "golden "opinions" from both the native and foreign residents of Hong-Kong, once the new coinage shall have found its way into the creeks and channels of general circulation, and thus proves its superiority to the clumsy and inconvenient currency which at present stops the way.

COMBINED RAILWAY AND CARRIAGE TRAFFIC BRIDGE ACROSS THE HOOGHLY.

For very many years the idea of throwing a bridge across the Hooghly has occupied the attention of engineers, and of the inhabitants generally of Calcutta. The magnitude, and, consequently, large expense of such a work, have prevented hitherto its accomplishment. At length, there does appear, however, a chance of the difficulties in the way of the prosecution of the enterprise being overridden. What the necessities of the half million of people who occupy the metropolis of British India could not effect, the railway companies are likely, and that very soon, to carry out. The site of the proposed bridge, it is true, is not precisely that which the residents of the city would have chosen; but, nevertheless, the structure will be of immense value to them, and they will look forward with anxiety and pleasure to the time of its completion. Some sixteen miles above Calcutta, the Grand Trunk Road crosses the Hooghly at the Pulta Ghaut, and then approaches and enters Calcutta through the fine avenue known as the Barrackpore Road. Half a mile above this, the river narrows from its average breadth, of nearly three-quarters of a mile, to 2,300 feet. At this spot, moreover, two lines of railway—the Eastern Bengal, and the East Indian—which run almost parallel for eighteen miles on either bank of the Hooghly, approach to within four miles of each other. The banks of the river at this point are high and stiff, and a series of experiments have proved that there is a good foundation in its channel. Here, then, it has occurred to the railway companies in question, is the best place for making a junction between the two lines. All the circumstances are comparatively favourable. Beginning at the surface of the water, there is an average depth of 16 or 17 feet at the lowest tides. The river flows over a bed of fine quicksand 28 feet in thickness, which covers another bed of solid clay 28 feet thick, and this, again, rests upon an old deposit of brown sand.

In and upon the bed of clay, it is proposed by Mr. Turnbull, Chief Engineer of the East Indian Railway, to lay the foundations of the bridge; but as the extreme rise of the tide, from the lowest in the dry season to the highest during the floods, is 21 feet, it follows that the surface of this bed of clay is 65 feet below high-water mark. The pressure likely to be exerted by the water on the piers and abutments, may be gathered from the fact that the tide frequently rushes up at the rate of 5¼ miles per hour, the lowest velocity of the current being 3½ miles, at half ebb. Mr. Turnbull has recommended a suspension girder bridge, with spans of 400 feet. The success of such a bridge on a large scale was first demonstrated in 1855 by Mr. Roebling, who constructed one above the Niagara Falls. The Niagara bridge has a clear span of 281 feet, with suspended stiffening girders of timber work. Though this bridge has now been open for traffic for seven years, and, on the average, thirty trains per day pass over it, it is as firm and sound as when first erected, and possibly even more so. The engineer of the East Indian Railway fixes his spans at 400 feet for the sake of economy, and for the purpose of

minimising interference with the navigation of the river.

The estimated expense of the piers is very heavy, and this arises from the fact that the cylinders must be sunk to a great depth in order to obviate danger from "scouring," and consequent deepening of the river. The suspended girder principle is preferred to the tubular girder, from a desire to lessen the weight upon the foundations. The Conway Tubular Bridge is, we are informed by Mr. Turnbull, of 400 feet span also, but its weight is 1,300 tons, whereas the weight of one span of the proposed structure will be only 550 tons, including the suspending chains and stiffening girders. Calculations, and the experience of the Niagara bridge, go to prove that, under these conditions, there would be no fear of undulations or serious deflection from passing loads.

The Hooghly Railway Bridge will, if Mr. Turnbull's plans be accepted—and of this there is little doubt—consist of lattice girders supported by chains. On the top of the girders there will be a common roadway; the lower joists or floor of the girders will carry a single line of rails. The strength of the chains will be such that they will sustain their own weight, that of the girders, and a train of 400 tons, with no greater strain than 5 tons upon the square inch. The undulation of the roadway with a train of 400 tons is not likely to exceed 2½in., which is less than the deflection of the Menai Tubular Bridge. The deflection of the girder under its own weight will be sufficient to compensate for the sinking caused by the lengthening of the chains from increase of temperature, and thus to insure that it will always be in contact with, and be supported by, the chains when the weight comes upon it. The object of the mode of construction proposed is not to produce a perfectly rigid roadway, which, indeed, is next to impracticable, but to take advantage of the great superiority of the suspension principle, by which the tensile power of the iron is alone brought into action at the same time that the only defect in the suspension bridge—namely, its undulation—is corrected by the stiffened roadway.

The bridge will be half a mile in length, with five whole spans of 400ft. each, and two half spans of 200ft. It will be approached on either side from the railway by inclines of 3½ miles, and the gradients will not be greater than 1ft. in 300ft. Between the suspension rods below there will be a width of 14ft. for the passage of trains, and above this a width of 20ft. for ordinary carriage and pedestrian traffic. To permit the passage of the largest river steam-boats with lowered funnels, there will be a clear distance of 25ft. between the bridge and the water.

We do not exactly see how the carriage roadway on the top of the bridge is to be approached, but probably that is a matter of detail which has been well considered and provided for. The total estimated cost of the structure is 280,000*l.*, and 64,000*l.* is set down as the expense of forming the four miles of connecting railway. Messrs. Brassey & Wythes, the contractors for the Eastern Bengal Railway, have signified their willingness to accept the works on these terms. It seems tolerably certain, that if this bridge be erected, the whole of the traffic of Northern India will cross the Hooghly at a point some four miles above the quaint old Danish town of Serampore, and enter Calcutta at Sealdah. We have said that the site of the new bridge is not precisely that which is most palatable to the residents in Calcutta, but we see no impossibility, at some future time, in that city being connected by an ordinary traffic bridge with its opposite neighbour, Howrah. The width of the Hooghly at Calcutta offers no insurmountable barrier to such a work, and British engineering talent, we feel assured, would easily surmount all other difficulties in the way of its accomplishment.

"TEMPLETON'S PRACTICAL ASSISTANT."*

THE second edition of this useful little volume has been issued under the following circumstances:—The author, who has spent nearly ten years in foreign countries, found, on his return from abroad, where no such works were to be had, his little treatises, published more than thirty years ago, still in demand, and it occurred to him to issue a new edition, embodying in a concise form the results of his long practice in various parts of the world. This he has now done, so far as the present book is concerned, which is a perfect *vade mecum* for all who are practically engaged in mechanical pursuits. As a work of elementary instruction in those calculations with which every mechanic should be familiar, it is replete with invaluable information, whilst as a book of "useful reference for those who are "of necessity compelled to give a ready answer "to any mechanical or engineering question," it is a little gem. It can be conveniently carried in the pocket, and contains, in 106 clearly-printed pages, the pith of what is ordinarily to be found only by consulting special large and expensive volumes. The work contains an introduction to decimal arithmetic; tables of decimal equivalents and approximates, and specific gravities; the weights of square, round, and flat bar iron in avoirdupois; of balls, nuts, bolts, and threads; the various properties of metals; the cutting of screws and construction of wheels; some very valuable information on steam and the steam-engine, with tables and rules; the properties of the circle, sundry useful tables on general matters; and a copious index, which may be extended at the will of anyone using the book by the employment of some ruled blank leaves, which are bound up at the end. So much varied information compressed into so small a space, and published at a price which places it within the reach of the humblest mechanic, cannot fail to command the sale which it deserves.

SUBMARINE TELEGRAPHS.

IT is now twelve years ago since the first prominent undertaking in connection with submarine telegraphy startled the scientific world. This enterprise, which had for its object the connection of England with France by means of a subaqueous conductor across the Channel between Dover and Calais, was but the forerunner of numerous other schemes which have, with few exceptions, been eminently successful. Since then, a submarine telegraph company has been formed, which has been conducted by its enterprising directors with more than ordinary success.

The report presented at the half-yearly meeting of the company last week contained some important features, which will be of interest to our readers. It commences by congratulating the shareholders upon the clear accounts "which fully justified the directors in the confidence which they had always expressed in the great resources and value of the property." It appears that the receipts exhibit an increase of 1,330*l.* 16*s.* over the previous year. Some idea of the extent of the business of the company may be obtained from the fact that during the six months ending June last, no fewer than 137,714 messages had been transmitted over their wires, which was in money value an increase over the preceding six months of about 1,398*l.* 4*s.*, while the working expenses have been reduced. But the returns of the current half-year are reported to be more favourable, being an increase over the corresponding period of last year of more than fourteen thousand messages. And out of the receipts of the company the directors are enabled to grant a dividend of 3 per cent. per annum for the last half year, besides handing over a balance of 620*l.* to be carried to the credit of the next account.

It appears that all the cables of the company are at present in good working order; their repair, however, though very heavy, had been less by about 2,000*l.* than the previous year. The repair of cables, indeed, will doubtless be always a considerable item in the expenditure of the company, as cables are often liable to get out of order. In an interesting speech which the chairman gave, in moving the adoption of the report, he mentioned the fact, that when their Ostend cable was broken in two, their engineer was able to restore it in nine days for 261*l.*, which he considered to be very encouraging, as showing that an accident to a submarine cable did not always necessitate a heavy outlay. It appears that the British and Irish Magnetic Company, with whose lines the wires of the submarine cables were united, have extended their system to Bristol and the south-west district of England and Wales. From this extension the company anticipate a considerable amount of continental traffic, which will secure them a more adequate portion of profit for the much greater risk incurred by their submarine lines. One of the most interesting features of the report was the refunding to the company by the French Government the caution money which they had retained, to guarantee the due performance of the concession in respect of the efficient working of the Dieppe cable. This cable, which was the first laid, had been, it appears, purchased by the company when it was in financial difficulties, and under pressure from the French Government, that it should be laid within a certain time. Notwithstanding these depressing circumstances, the company have found it to turn out better than it appears they had anticipated; and it was now in perfect working order. The last, but not least, item of favourable intelligence with which the report abounded was, that "the traffic was likely to improve, as the Italian Government were about laying down a submarine cable between the southernmost point of Sardinia and Marsala, so that the long delays which occurred to telegraphs, while being transmitted over the central Indian lines, would be avoided."

The increase of the business of this company might be attributed to the International Exhibition; but this the chairman denied. He said, indeed, that he believed very little came from that source, though they had opened an office outside that building, which was doing a steady business. The company had not been able to obtain an office inside the Exhibition, as the commissioners had granted the exclusive monopoly to the Electric Telegraph Company. This the directors have every right to consider as unfair and exclusive. The increase of business seems to have been the fruit of the gradual and steady development of telegraphy on the Continent, and the encouraging manner in which they had been treated by the French and Belgian Governments; and from the speeches which were given at the half-yearly meeting, there seems to be an anticipation, which we earnestly hope may be realised, of an increase of business to such an extent that the most sanguine of the shareholders had not anticipated.

THE INTERNATIONAL EXHIBITION.

Class I.—Smelting Ores.

(Concluded from page 117.)

We have not discovered in the present Exhibition anything remarkable or novel respecting tin. The usual tin-stone, which is impure peroxide of tin, will be found in the British department from Cornwall, in the Indian, in the Portuguese, and in that of Victoria, No. 479. The specimens in the last but one will no doubt attract the notice of interested persons, who will find numerous details concerning their mode of occurrence, &c., in the Portuguese catalogue, Nos. 34, 37, 7, 30. In 1860 Cornwall and Devon produced 10,500 tons of tin ore, which yielded 6,700 tons of metallic tin—(*Mineral Statistics*, 1861). In the metallurgy of this metal there is nothing either new or important. Michell and Co., of Marazion, Cornwall, exhibit an excellent model of the usual reverberatory smelting furnace, and a series of the products obtained (No. 226). These gentlemen have nothing to gain by their contribution, except the thanks of the public, to which they are justly entitled. Mr. Oxland displays a series of specimens illustrative of his method of separating wolfram from tin ores (No. 258), similar to that which he placed in the Exhibition of 1851. In the Zollverein are ingots of tin from Altenberg (No. 2,301), and this is the only contribution which the kingdom of Saxony has condescended to make! On referring to Dufrénoy's report of Class I. in the Exhibition of 1851, we find the following passage:—"Saxony and the Harz, those cradles of mining, which for so long in Europe enjoyed the honour of possessing mining schools, have sent none of their products." Saxony no longer occupies the proud position of former times. There are other cradles besides hers in Europe, and if, in a spirit of exclusive self-sufficiency, she chooses to keep aloof, let her do so, and the world will progress without her. Tin and Saxony will, perhaps, henceforth be coupled in a sense of unenviable notoriety.

Lead may be quickly despatched. Galena occurs in nearly all the departments of the present Exhibition—namely, Great Britain, Sweden, the Zollverein, Austria, Belgium, France, Spain, Portugal, Italy, Canada, Newfoundland, Venezuela, Australia, &c. In 1860 about 90,000 tons of lead ore are reported to have been raised in Great Britain, from which were extracted 64,000 tons of lead, and 550,000 ounces of silver (*Mineral Statistics*, 1861). In the Swedish department is lead ore from Sala (No. 80 c), which, though of the largely crystalline character, contains considerably more than 100 ounces of silver per ton of lead. Many of the specimens in the Zollverein department, especially relating to the dressing of lead ores, are worthy of examination, but none require particular mention, except Nos. 789, 847. Under these numbers is shown a collection of specimens illustrative of, perhaps, the most remarkable and extensive deposits of galena in Rhenish Prussia. The galena occurs in small rounded shot-like particles, diffused through a bed of white Bunter sandstone, which sometimes attains a thickness of not less than 120 feet. The Italian and Portuguese departments should be carefully inspected with reference to their lead-producing capabilities.

There is nothing of particular interest in the Exhibition relating to the metallurgy of lead. We see many of the usual illustrations, which, though always interesting, yet do not require special comment. The best series in the British department is unquestionably that exhibited by Mr. Sopwith, on the part of Mr. Beaumont, whose name is so well known in connection with lead mining in England (No. 334). The processes of dressing and smelting are illustrated as well as they can be; and Mr. Sopwith, moreover, has added an excellent mining plan. The entire absence of some of the great lead smelters is to be regretted; for, although they can hardly expect to reap any pecuniary advantage from a representation in the Exhibition, yet they might contribute something, if solely with a view to the honour and glory of Old England. In the Zollverein and Italian departments are several interesting series in illustration of dressing and smelting; and among those in the last-named we may specially refer to the products obtained in smelting old slags. Considerable sums have been realised in this country and Spain from such slags, and it is well to keep a sharp look-out for their occurrence in districts where lead-smelting is known to have been practised in ancient times. Barker, Rawson, & Co., Sheffield, exhibit lead decopperised by processes exactly similar in principle to the two methods invented by Pattinson and Parkes respectively for the desilverisation of lead (No. 10). In the same case are shown pigs of lead obtained from slag lead by heating with nitrate of soda. These pigs are stated to be of remarkable purity, notwithstanding they present a bright and highly crystallised surface, which has hitherto been regarded as an unequivocal sign of impurity. We heard a lead-smelter of some experience pronounce them at first sight to be made from slag lead, on account of their crystalline surface; and so they were. But the character of the surface is probably due to the fact of the solidification of the metal under a well-melted flux. There is nothing in the Exhibition to indicate that progress has been made towards the solution of the great problem of condensing lead fume. In the last Exhibition the Duke of Buccleuch exhibited a model of a condenser which he had adopted for the purpose. Are our great smelters doomed for ever to witness the melancholy spectacle of the daily escape of enormous quantities of lead from their chimneys? We refer, of course, to those smelters whose works are in localities where it would be impossible to construct horizontal flues a mile or two in length, as in Derbyshire and the North of England. Bishop Watson, in his admirable *Chemical Essays*, has given an account of the origin of these flues; and, as the subject is now particularly interesting in reference to Lord Derby's proposed legislation on "noxious vapours," we subjoin an extract or two. After stating, with becoming modesty and good sense, that he is aware "that what may appear very feasible in theory, or may even answer in small assays, may not be practicable in large works," the good Bishop proceeds as follows:—

> The first alteration which I would propose to the consideration of the lead-smelters is to substitute a horizontal chimney, of 200 or 300 yards in length, in the place of the perpendicular one now in use. . . . . [The smelters were all] of opinion that the plan I had proposed for saving the sublimate was a very rational one. But so difficult is it to wean artists from their ancient ways of operating that I question very much whether any of them would ever have adopted the plan they approved, if a horizontal chimney which was built a little time ago in *Middleton-dale*, for a quite different purpose, had not given them a full proof of the practicability of saving the sublimate of lead, which is lost in the ordinary method of smelting. This chimney was built on the side of a hill, to prevent some adjoining pastures from being injured by the smoke of the furnace. It not only answers that end, but it is found also to collect considerable quantities of the lead, which is sublimed during the smelting of the ore; this sublimed lead is of a whitish cast, and is sold to the painters at ten or twelve pounds a ton.—(Vol. iii. p. 282, 1782.)

The general reader will have an idea of the prodigious amount of lead which may thus be saved, when he is informed that in one year a large smelting establishment in the north of England obtained 800 tons of lead from the dust accumulated in their long flues! Expedients of various kinds, some of them costly, have been tried with a view to the complete condensation of lead fume; but there is not one which is in all respects satisfactory.

Arsenic, so far as Class I. is concerned, is sufficiently represented in the Exhibition. This metal is rarely employed in the metallic state, and is required in the arts chiefly in the state of arsenious acid, which is commonly called white arsenic, or simply arsenic. This poisonous substance is produced on a very large scale in metallurgical works, either as a primary or as an accessory product. It generally occurs in commerce in the state of white powder, which is prepared by grinding arsenical glass previously obtained. When first produced this beautiful substance is colourless and perfectly transparent: but, like barley-sugar, it becomes opaque on keeping. Arsenic enters into the composition of numerous pigments, and has of late been extensively employed, in the state of arsenic acid, in the preparation of rosaniline, or the so-called Magenta colours. We have pleasure, however, in assuring our fair readers that not a trace of this poisonous metal is retained in these beautiful colours. White arsenic is used for seed steeping, and is frequently sold, under certain restrictions, for poisoning—*of course only rats!* In metallic combination arsenic plays an important function in certain metallurgical operations, and we may probably frighten our readers when we inform them that we could point to chimneys in populous districts in England which have unceasingly vomited forth arsenic by the ton during these last twenty years! And, so far as we know, not a single case of injury to man or beast has occurred in consequence. For obvious reasons we decline to excite unnecessary alarm by naming localities. When the skin is much exposed to contact with arsenic, it is liable to eruptions of a particularly disagreeable character. The dare-devilism of the men employed in arsenic works is really surprising, and in proof of this we will narrate our experience of a visit to large arsenic works not long ago. We received the most courteous attention from the manager, a man of middle age, the very picture of exuberant health and quiet contentment. After we had entered his office, with a view to our instruction, he seized a big lump of arsenical glass and gave it a thundering blow, which scattered it in innumerable fragments about the room, nearly every one of which would have sufficed to destroy human life. "We think nothing about it," says our friend. "But don't you ever suffer?" "Oh, yes, occasionally, but we vomit and think no more about it." "What as to the eruptions on the skin?" "Arsenical—look at my neck, you see the remains of it." So we did. We then went to the furnaces, where the first object to attract attention was a sickly-looking man, who might have been mistaken for a miller. The arsenious acid condenses on the interior of long flues, forming a beautiful white crystalline incrustation, and this is detached through numerous side doors. "We find the best way to do this," said our guide, "is to put a towel round the face and mouth, and stop up the nostrils with cotton wool." The grinding of the solid lumps o arsenical glass *dry* between millstones, and the subsequent packing of the powder also *dry* in casks, is nasty work, as may well be imagined.

Garland, of Redruth, No. 114, and Jennings & Co., of Swansea, No. 169, send instructive collections illustrative of the manufacture of white arsenic; and if we have omitted to mention other exhibitors of these articles, it is accidental, as we did not notice, on our visit to Class I., any marked differences between the arsenical collections exhibited. In the Zollverein department there are two collections, Nos. 821 and 783. The former is from the old Reichenstein Works, in Lower Silesia. The ore is arsenical iron, which is slightly auriferous, and it is from the ferruginous residues that gold was first extracted on a large scale by chlorine water. The second is fr m Breslau, Silesia. Both collections include red and yellow, in addition to white arsenical glass.

We now arrive at the consideration of a metal which has only recently become an important object of manufacture—namely nickel. The word is German, and in the sense in which it has been adopted, as the specific name of this metal, it indicates a worthless and meretricious character. Its chief ore, from its reddish colour and deceitful appearance, is called by the Germans Kupfernickel, which is commonly translated "false copper." According to the recent researches of Deville, pure nickel is malleable and ductile, and has a much higher tenacity than wrought iron. What say you to this, Sir William Armstrong and Mr. Whitworth? It is not yet employed in the state of pure metal, though we have known small horseshoe shaped castings of nickel made solely with the view of evading a particular patent, in which the use of articles of a similar shape in iron had been claimed. Another example of the wisdom of our patent laws! Nickel is used as a constituent of alloys, generally with the object of communi-

cating *whiteness.* German silver—a name, by the way, which our Teutonic brethren indignantly repudiate — is a triple alloy of copper, nickel, and zinc. It might, in fact, be properly called white brass; but there is a good deal in a name, even among metals, and if it had been thus christened there is no knowing what its fate might have been. It was introduced about thirty years ago, especially as a substitute for silver forks and spoons, and a precious substitute it was! To compare the German silver of that time with silver in respect of colour was absurd, and when handled it evolved the disagreeable odour of copper or brass. In process of time an improved article, having really an argentine colour and susceptible of a fine polish, was produced; still with respect to odour it was rankly coppery as before, and so it ever will be. The manufacture became established in Birmingham, and the firm which is unquestionably entitled to the credit of having effected the greatest improvements, and brought it to its present state of perfection, is the well-known one of Evans & Askin. The last-named partner died in Norway in 1847, and it was he who had charge of the manufacturing department. Some time about 1840 the then new process of depositing metals by the agency of voltaic electricity attracted attention in Birmingham, and Messrs. Elkington & Co. obtained patents for plating on this principle. German silver was just the alloy required for silver plating. From its greater hardness it was much better able to resist wear than copper or brass, and it had the additional advantage of being white—so that, if the silver deposit should in the course of time be worn off the ends of forks, &c., the metal exposed would hardly be detected, the reverse of which is the case in similar circumstances with the copper articles silver-plated by the old method. We have all seen those shabby would-be genteel old candlesticks and waiters at inns, on the surface of which it was difficult to say whether silver or copper most prevailed. German silver was adopted by the silver electro-platers, and the German silver trade was at once established on a solid basis, and it has since acquired considerable developement. Nickel has fluctuated considerably in price during the last twenty years. It is now extensively employed in monetary coinage. The Swiss were the first to adopt it, and introduced a quadruple alloy, consisting of copper, nickel, zinc, and silver — an alloy against which, if space permitted, we might urge grave objections. Nickel is now used in the coinage of Belgium and the United States, and possibly in other countries also. The Master of the Mint, it is well known, proposed to employ it in our new copper coinage, but the Chancellor of the Exchequer, Mr. Gladstone, put his veto on the proposition, for reasons probably more satisfactory to himself than to anybody else. Birmingham is solely entitled to the credit of having brought the nickel manufacture to its present perfection.

We may here record a fact of interest to the manufacturing public, and which we have never seen published. The late Mr. Alexander Wright, a surgeon of Birmingham, discovered the value of cyanides of potassium and sodium as solvents for silver in electro-plating. The application was immediately patented, and the patent was afterwards purchased by Messrs. Elkington & Co. This application has proved of immense value to the electro-plater in every respect. Mr. Wright was led to this important invention from reading a passage in *Scheele's Chemical Essays* (pp. 405, London, 1786). So much for old books. At first, Mr. Wright received a royalty of 1*s.* on every ounce of silver deposited; but after his decease, which took place not long afterwards, a different arrangement was made with his widow. There is also another incident which deserves to be recorded, as it has now particular significancy in this time of patent law amendment agitation. The late Mr. Woolrych obtained a patent for the application of the voltaic current from the magneto-electric machine to the plating of metals; but then came the question of solvents, for Messrs. Elkington & Co. had not only secured the cyanides, but had obtained a patent in which Dr. Leeson had specified some 400 solvents. (A.D. 1842, No. 9,374.) It so happened that certain salts were not included in this list, because it was supposed that they could not be employed for the purpose — namely, the alkaline sulphites. Mr. Woolrych luckily found that this was an error, and claimed the use of these identical salts in his patent. Subsequently the patent of Mr. Woolrych became the property first of Mr. Evans, of the firm of Evans & Askin, and afterwards of Messrs. Elkington & Co. It is not improbable that, considering the skill, energy, and taste which this firm has displayed, and which are universally acknowledged, they would have attained equal success without having been nursed in a hotbed of monopoly.

Ores of nickel are exhibited by the manufacturers of German silver. Nickel has been found in small quantity in Cornwall. It has been largely produced in Hungary. In the Zollverein department nickel ores will be met with under the following numbers — 801, 786, 704, 619, 620. Magnetic iron pyrites, containing nickel, has been found in numerous localities during the last few years, and has been largely worked at Espedal, in Norway, by Evans & Askin, who have, however, abandoned this establishment. It occurs in Argyllshire, on the property of the Duke of Argyll. Specimens of such pyrites will be found in the Norwegian department, under Nos. 3, 13, 15. A large mass of similar pyrites is in the Italian collection, No. 66. The ore, we believe, is smelted on the spot, and the regulus obtained is sent to Belgium, where it is refined near Liége. It is singular that this species of iron pyrites should so frequently contain nickel.

Evans & Askin make an excellent display of their nickel and German silver, No. 100. There is a large ingot of nickel which a few years ago would have been regarded as a marvel, and well do we remember the time when it was considered an achievement to fuse a bit of nickel scarcely larger than a pea. Mr. Vivian established nickel works at Swansea a few years ago, and through the Swansea local committee exhibits the products of his manufacture, which, so far as inspection will enable us to judge, leave nothing to be desired. Those who are interested in nickel may study the following collections in the Zollverein department: — From Iserlohn, by Dr. Fleittman, No. 717; from the Mansfeld Copper Works, Eisleben, No. 786; and from Dillenburg, Nassau, Nos. 620 and 619. In the Swedish department is shown an alloy of copper and nickel in powder, which is stated to be a metallurgical product, No. 80; nickel and smelting products from Smaland, No. 37; and an alloy of nickel and iron, No. 5, of which we have not succeeded in obtaining the history.

Next in order comes cobalt. This is a metal which, chemically speaking, is very closely allied to nickel, but in some respects is widely different. Both metals are frequently associated in nature — so much so, that when one is present in an ore the other is usually looked for. It is not employed in the metallic state. In the state of protoxide it is the base of various well-known blue pigments of the highest importance in the arts, especially those of pottery and glass making. Its chief value is due to its property of forming beautiful blue colours when in combination with silica and potass; but it also yields blue colours when combined with certain other elements. Smalts is only the fine powder of a glass coloured with cobalt. This pigment was formerly the only one used in communicating a blue tint to ordinary writing paper; but it has been generally superseded by the cheaper material known as artificial ultramarine. It is still employed to produce the blue tint of starch. The Government works in Saxony once enjoyed a monopoly in the manufacture of this article[1]; but not so now-a-days. The preparation of smalts is always described in metallurgical works, and should, therefore, belong to Class I.; but it is excluded from that class in the present, as it was also in the last Exhibition, and so we dismiss it from consideration. Oxide of cobalt is now largely prepared for the use of the potter and glassmaker in Birmingham, where the manufacture was first introduced about twenty years ago, by Evans & Askin. The separation of nickel from cobalt was at one time regarded as a difficult problem, even n he laboratory of analytical chymists; but the late Mr. Askin was so fortunate as to discover a process by which the separation might be economically effected on the large scale. The ores which they were accustomed to employ in the production of nickel frequently contained cobalt, and, as the presence of cobalt in German silver is injurious, it was desirable to eliminate it on this account alone. By Mr. Askin's process it was obtained as oxide practically pure, and this oxide, which at first was virtually a *waste product*, was for some time sold to the potters at two guineas a pound! The present price is about one-fourth of that sum. Hence, as may be readily supposed, a considerable fortune was speedily amassed. The fine "flowing blue" on our china, which attracted much attention some years ago, was the result of the first application of this oxide. Two oxides are now articles of commerce — namely, the *black* or requioxide, and the *prepared* or protoxide. As secrets will out, so the firm of Evans & Askin were not long allowed to enjoy their monopoly undisturbed, and rival manufacturers started into existence, some of whom failed utterly in carrying out the process. We have seen the name of Louyet, a deceased Belgian chemist, coupled with this new process, as though he had been the inventor! He had no more to do with it than the man in the moon! He visited Birmingham and inspected one of the rival establishments above-mentioned, with the manager of which he was on terms of intimacy, and subsequently published what he had seen, whether with or without authority we do not know. We have availed ourselves of this opportunity of vindicating the claim of our countryman, Askin, as the inventor of the process in question.

Cobalt has only been sparingly met with in this country. Ores specially of cobalt will be found in the Zollverein department, under No. 811. They also occur in the United States and the western part of South America. Saxony might have sent specimens.

In 1860 cobalt ore was imported into England to the amount of 341 tons, and of the declared value of 13,895*l.*; and nickel ore to the amount of 14,000 tons, of which the value is not given (*Mineral Statistics*, 1861). The nickel ore, doubtless, contained a considerable quantity of cobalt.

Messrs. Evans & Askin show the products of their manufacture. Mr. Vivian also shows his; but among the latter we do not observe any specimen of "printers' blue," an article which, at one time, was largely produced for the potters' use by the first-named firm, by whom, indeed, a sample is now exhibited. — *The Times.*

THE TRUE PRINCIPLES OF AIR NAVIGATION EXPLAINED.

TO THE EDITOR OF "THE MECHANICS' MAGAZINE."

LETTER 3.

SIR,—Of the three principles, the most difficult one to contend with has ever been

THE MOTIVE POWER.

By carefully preparing a composition capable of supporting combustion gradually and uniformly in closed chambers, we may obtain by far the most economical and energetic motive power possible, because by the use of such composition its conversion into gaseous matter can be obtained by more compact mechanism than that required for any other controllable prime mover. For not only can we secure the whole of its gaseous matter, but by surrounding the combustion chambers with water the whole of the heat evolved during combustion is rendered also available by the generation of steam; and thus both the steam and gaseous matter collected in the steam space of the generating cylinder combines to produce the impelling force. To obtain an adequate conception of the relative value of this force we must compare the volume of gaseous matter and vapour evolved by equal quantities of gunpowder, water, and coals, and this composition, under the atmospheric pressure.

Grains, troy.		Volume of gas or vapour.
1	of the finest gunpowder (Hall's)	10 cubic in.
1·1	of water and coals (·1 gr. coals)	6·5 ,,
1	of composition, exclusive of water* . . .	3·2 ,,

The time required to convert these substances respectively into aeriform matter should also be taken into account; but as the conversion of any quantity of gunpowder would be instantaneous, and that of water dependent on the evaporating surface, that of the composition may be as quick or slow as we please; so that any comparison would be useless.

The great expansive force of gunpowder is entirely due to the liberation of the gases at a luminous heat, and the velocity of radiation of such heat being much less than the velocity of expansion of the gases. For if we overpower the instantaneous liberation of these gases, and consequently the velocity of expansion, we have these effects reversed; *i. e.* the radiation of the heat has the greatest velocity, and the expansion or liberation of the gases the least velocity. If we ignite a grain weight of gunpowder under a weighted piston, the keenest eye cannot follow the velocity of expansion, and the heat evolved, though intense, will scarcely increase the temperature of the cylinder. If, on the other hand, we ignite a similar quantity of composition under the same weighted piston, the eye can easily perceive the velocity of expansion, and the heat evolved will considerably increase the temperature of the cylinder. It is therefore probable that the same quantity of heat is evolved from equal quantities of these substances during their combustion, but in very different quantities of time; that of powder very suddenly, but that of the composition as gradually as we please. Here, then, is the great importance of this composition as the principle of power for our use, because the whole product of it is available for impelling the piston uniformly at any velocity and pressure we please; and it is rendered still further valuable by the circumstance of its constituents being nearly all recoverable for recombining for future use.

The next principle demanding our attention is

WEIGHT.

This we must have—unalloyed by buoyancy—for without weight the air cannot be compressed, or the third principle—

ELASTICITY,

or resistance to compression—developed. But this weight must not be excessive, or the power will be wasted, or its use for transmitting valuable cargo greatly diminished. The weight will, of course, depend upon the size of structure, but for one of the following dimensions, viz., 14ft. long, 7ft. wide, and 6ft. high, fitted with generating cylinder 16ins. diameter and 40ins. long, and with all other necessary apparatus, need not exceed half a ton; to which we may add 5cwt. of composition for generating and maintaining its power. If to this we add an equal weight as useful cargo, we then have a total weight equal to 1½ tons. By employing 4 propellers, each 4½ft. wide by 9ft. long, we have a total surface equal to 162 sq. ft. to raise and support this weight in the air.

Having therefore (as in the case of the birds, or in comparison with the female bird, a body of 2000 times the weight and doubtless the power), the weight of this body and the surface of the propellers for raising and maintaining such weight in the air, we have first to find the true velocity required of such propellers. As before, we have $\frac{P\times S}{W}=c$, and $\frac{V}{c}=x$; then $\frac{x}{a}=y$ is the number of actions required.

The atmospheric pressure on one square foot is $14\cdot5\times144=2088$lbs., or say 1 ton. By raising and depressing the propellers through an angle equal to 90° on each side of the body, we have this surface propelled through 180° of a circle 9ft. in diameter; therefore through a space equal to 14·14 feet at each stroke. Consequently,

* I have had no means of ascertaining what quantity of water can be vaporised by the heat evolved from a given quantity of this composition, but I think it not unreasonable to estimate its heat-giving power at one-fifth that of coals; if so, we have (from 5 grains, $3\cdot2\times5+6\cdot5=22\cdot5$ or) 4·5 cubic inches of gas and steam generated per grain.

$\frac{1\times162}{1\cdot5}=108$, and $\frac{1200}{108}=11\cdot11$ft. per second, the velocity required. Then $\frac{11\cdot11}{14\cdot14}=\cdot79$ stroke per sec. or 47·5 revolutions per minute. This velocity of the above surface will develope a resisting force from the elasticity of the air equal to 1½ tons, and therefore the impelling force on the surface of the pistons must equal 1·5 tons + 10 per cent. for overcoming friction of machinery, or a total impelling force of 1·65 tons. By employing two cylinders of 4ins. diameter each, we have a piston surface equal to 25 sq. ins., which will require a steam pressure equal to 150lbs. per sq. in. through the length of the stroke to equal 1·67 tons impelling pressure. To obtain this pressure we must produce 9,500 cubic ins. of gas and steam per minute, of a density or pressure equal to 10 atmospheres. Then as 1gr. of composition produces 4·5 cubic ins. of gas and steam combined, of a density equal to one atmosphere, the product of 10grs. will be 4·5 cubic ins. of the density or pressure required; and $9{,}500\div4\cdot5=2{,}111\times10=21{,}110$grs., or about 3lbs. per minute, is the quantity of composition required to be converted into a propelling force for raising and maintaining in the air a body weighing 1½ tons.

To estimate the speed, we may take the surface opposing forward motion as equal to its greatest cross section, or 6ft. by 7ft., equal to 42 sq. ft. As the impelling effect obtained from the upward stroke of the propellers is equal to the power expended in that motion, we have a progressive force equal to 3,375lbs. to be neutralised by the resistance to forward motion. Consequently, $42\times190^2\times\cdot0023=3{,}400$lbs., or a speed of nearly 130 miles per hour can be attained before the resisting and the impelling forces will become equal.

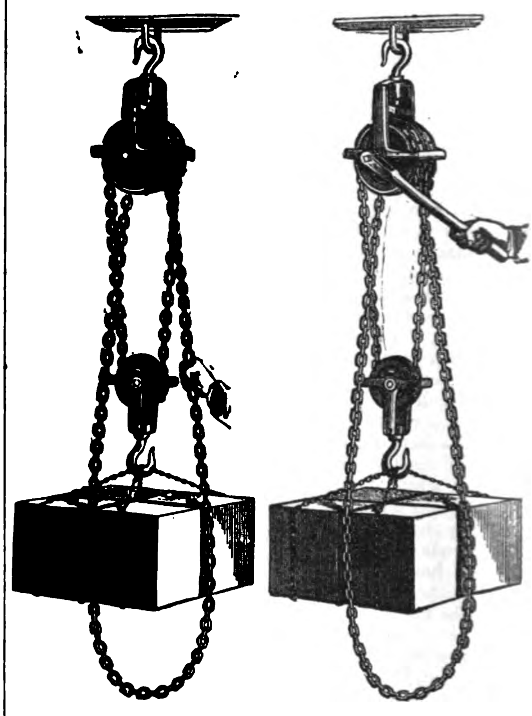
Birds, more conspicuously than any other animals, derive from the action of their propellers sufficient momentum for supporting and conveying them through a considerable distance after suspending all action of them; but we must guard against believing that during the time they are thus held suspended, the bird always descends by the force of gravity, for if they so willed they can and do ascend. This I have particularly noticed in order to decide this point. Continual action, therefore, is not required of them for their support, although they continue to rise and to proceed. This circumstance, as well as the rapid flights attained by various classes of birds, proves that their rate of progress does exceed the rate of motion imparted to their wings. It is evident that while the impelling effect obtained from the elasticity of the air by the upward stroke is equal to the bird's power expended in that motion, the resistance to its forward motion is the same as to that of a body projected longitudinally, and to which only the law of the square of the velocity is applicable.

Bishop Stanley states that "a pigeon flew 23 miles in 11 minutes, or at the rate of 125½ miles per hour." If we take the surface opposing forward motion (equal to the cross section of the bird's breast and anterior margin of the wings) at 7 sq. ins. or ·05 sq. ft., we have this extent of surface virtually resisting progression, and which at 125 miles per hour, or 183ft. per second, would meet a resistance $=183^2\times\cdot0023\times\cdot05=3\cdot8$lbs. We have seen that the elasticity of the air supplied a resisting, and, therefore, a progressive force equal to 1·3lbs. to the female bird's propellers. This bird was stronger on the wing than the male bird. If we suppose the bird that accomplished the above speed to have been stronger than this female bird, and that it could perform twice the number of strokes in the same time,—*i. e.* about eight strokes per second—and supposing their weights and the surfaces of their wings to be equal, then it would have developed twice the resistance to the surface of its propellers, or about 3lbs., and if the increasing momentum derived from its weight is taken at 25 per cent., which is not unreasonable in air, making the total $=3\cdot75$lbs., we have the resistance to forward motion, and, therefore, the speed satisfactorily accounted for; and that the bird would not (as according to the theory of some men) require to work its wings at the inconceivable velocity of 183 feet per second! (which is about three times the velocity of a locomotive engine) to obtain that rate of progress. Again, if we take the speed stated to be more generally attained by carrier pigeons, viz., 50, 60, or even 70 miles per hour, then the ordinary velocity of two or three actions per second would develope as much progressive force by the upward stroke as the resistance to forward motion at such speed would neutralise; 70 miles per hour, for instance, generating a resistance $=1\cdot2$lbs. only on an equal surface as the above.*

Yours, &c.,
W. Quartermain.

* A model, embodying the principles here advocated, can at any time be seen in the Polytechnic Institution, Regent Street, London.

WESTON'S DIFFERENTIAL PULLEY BLOCKS.



The peculiar merit attached to these pulleys is, that whilst they are more powerful than ordinary pulley blocks, they also possess the novel and invaluable quality of not "running down," under any circumstances, whilst the load is suspended to them.

The action of these pulleys may be thus explained:—The upper block has a double sheaf of two different diameters, with teeth gearing into the endless chain, which hangs from it in two loops, in either of which is placed the single block, having a hook for attaching the weight to be hoisted. If the toothed sheaves of the upper block were of equal diameters, the weight would remain stationary, whilst the endless chain was passing over them, owing to the same length of chain being drawn up on one side as was being pulled down on the other side; but as one sheaf is larger than the other, and as both sheaves being fastened together (or made in one piece) work together, the large sheaf takes up more chain than the small sheaf does, consequently the weight is raised proportionally. The purchase is about 22 to 1—that is to say, when 22 links of chain pass over the large sheaf, the weight is lifted the length of one link. This ratio is, however, varied in the different sizes and powers.

Each set has two speeds, a fast one—by pulling the chain—for light lifts and for running the tackle up or down to any desired point; and another—by using the lever and ratchet as represented, which gives a lifting power equal to an ordinary crab and blocks combined.

Lifting and lowering are effected by pulling opposite sides of the loops, either the slack one or that which bears the weight; or for the heavier weights, when using the lever, the motion is reversed by turning it over to work in an opposite direction.

A weight hung to the single block, in either loop, does not run back, even if the chain is suddenly let go, because the opposite sides of the loop pull against each other on opposite sides of the double sheaf.

These pulleys are exhibited at the International Exhibition (close to the Suez railway carriage), No. 2,020, Eastern Annexe, by Messrs. S. & E. Ransome & Co., Essex Street, Strand.

THE PARIS PERMANENT UNIVERSAL EXHIBITION.

WITHIN the precincts of New Paris, in the flourishing district of Auteuil, where Boileau gave poetic counsel to his gardener, where Molière composed his *chefs-d'œuvres* in the company of Racine, De la Fontaine, and De la Bruyère, Industry, the queen of our epoch, is raising, at this moment, a palace to modern genius. Its aim is to place upon a new footing exhibitions, the utility of which is incontestable. They began by being exclusively national and temporary. From being national they became universal. Henceforth the products of science, the arts, industry, agriculture, and commerce, will find a place in an universal and permanent exhibition. The splendid palace now building at Auteuil proves that the idea is leaving the realms of theory, and approaching realisation. Let us first examine the practical advantages of the scheme; we will then describe the building and its workmanship.

Persons are fond of repeating that distance is annihilated, that frontiers are disappearing, and that modes of international communication are being multiplied. It is true. They delight in exalting the marvels wrought by the union of science and labour, the grand modern discoveries, the admirable inventions of industry—and with good reason. But it is of the utmost importance to develope all the branches of human activity, and to expedite commercial transactions. The Universal and Permanent Exhibition offers these advantages, for its object is to bring together the producer and the consumer. It will save the one numberless researches—often unproductive. To the other it will offer a continual stimulus, and place at his disposal objects from all quarters of which he has need.

In periodical exhibitions one often sees exceptional works, true exponents of ability, but executed at great cost, and addressing themselves more to the curiosity of sightseers than the approval of practical men. These productions, which aim at effect, and are not meant for ordinary use, ought not to enter into competition with the samples of industrial labour. The Universal and Permanent Exhibition, on the contrary, will give satisfaction to industrial and commercial interests. It will tend to improve the welfare of the labouring classes, by leading the producer to unceasingly improve his work, until he at length attains a point combining excellence with economy. We are able to add that the scene of this specific tournament will be worthy of the city which Europe truly considers the capital, not only of France, but of the whole world.

The idea once conceived, its realisation was imperative. This is often the most difficult part. Happily for the project of universal and permanent exhibitions, it has found powerful support among large capitalists, who have undertaken to defray the cost of construction. When the building is finished, it will be placed at the disposal of exhibitors, a very long list of whom is already published. The programme is headed by those memorable words which were uttered by an august personage on a solemn occasion.—"Approach, all you who think that the progress of agriculture, the industry, and the commerce of a nation contributed to its general welfare, and that the more reciprocal intercourse is multiplied, the more national prejudices will be effaced." Also when this project was submitted to the Emperor, His Majesty was pleased to express to its authors his approbation of it, and the pleasure with which he should regard its realisation. Their Excellencies the Ministers of Finance, Agriculture, and Commerce, have accorded, by two official despatches, various permissions which show the sympathy of the Imperial Government with the idea of establishing in Paris an exhibition universal and permanent.

For a project of this nature the choice of site was of the greatest importance. Of course the founders would have greatly preferred to establish themselves in the centre of Paris. But they encountered insurmountable obstacles. How could they find in the heart of a great city an area sufficiently extensive (130,000 square mètres)? And even if they had overcome this first difficulty, the excessive value of the ground would have alarmed the greater number of exhibitors. At the same time, it was necessary that this site should not be too distant from business quarters, and that it should be united with the capital by rapid and economical means of communication. A large piece of land, situated on the verge of the Bois de Boulogne, between the gate of St. Cloud and the station at Auteuil, united all these advantages. It is now the property of a company, and the workmen are progressing with such rapidity, that already the plan of a monumental palace intended to receive the artistic and industrial products of the whole world is clearly defined.

When an edifice of this kind is required, its proportions must be colossal. The palace at Auteuil will present a *coup-d'œil* 500 mètres in length, that is to say, an elevation double that of the Palace of Industry in the Champs Elysées. The façade will extend along the new Boulevard granted by the city of Paris, commencing at the banks of the Seine, and terminating at the main street of Auteuil and the other ways of approach, which will complete the Parisian network. The effect will be magnificent.

Imagine one of these constructions invented by modern architecture, light, but solid, where iron and glass rest upon stone foundations. An entrance portal, in keeping with the grandiose character of the edifice, will give access to the centre of the building, which will be crowned by a dome more lofty than that of L'Hôtel des Invalides. At each end of the structure, elegant pavilions will complete the palatial effect, and will be accompanied on the right by a Machinery Annexe, on the left by a vast rotunda, intended for concerts and charitable fêtes. Such is the *tout-ensemble* of the building in course of construction by an army of workmen, under the direction of skilful engineers.

In the interior, the height of the building will be divided into two stories; but, by a happy arrangement, this division will not show externally, and one range of windows, extending the whole height, will give light to the treasures exposed in the galleries.

We hope (and the activity which presides over the work authorises us to entertain this hope) that the inauguration of the Universal and Permanent Exhibition will take place early in the ensuing year. Meanwhile, the enterprise is organised on a solid basis. The most influential representatives of universal industry have already sent in their adhesion, and head the list of exhibitors. This adhesion, however, does not at present imply any pecuniary contribution. The founders are liable for all expenses, up to the time when the exhibitors take possession. We may add, that during five days of the week, admission will be gratuitous, and that the detailed internal regulations will be settled by committees from the different nationalities.

Such has been the rapid advance of an idea, conceived in a liberal and straightforward manner. It deserved to be conceived and carried out in an epoch which has already accomplished such grand undertakings, and in a kingdom where industrial progress advances in concert with the national grandeur.—*Translated from "Le Constitutionnel," August* 28, 1862.

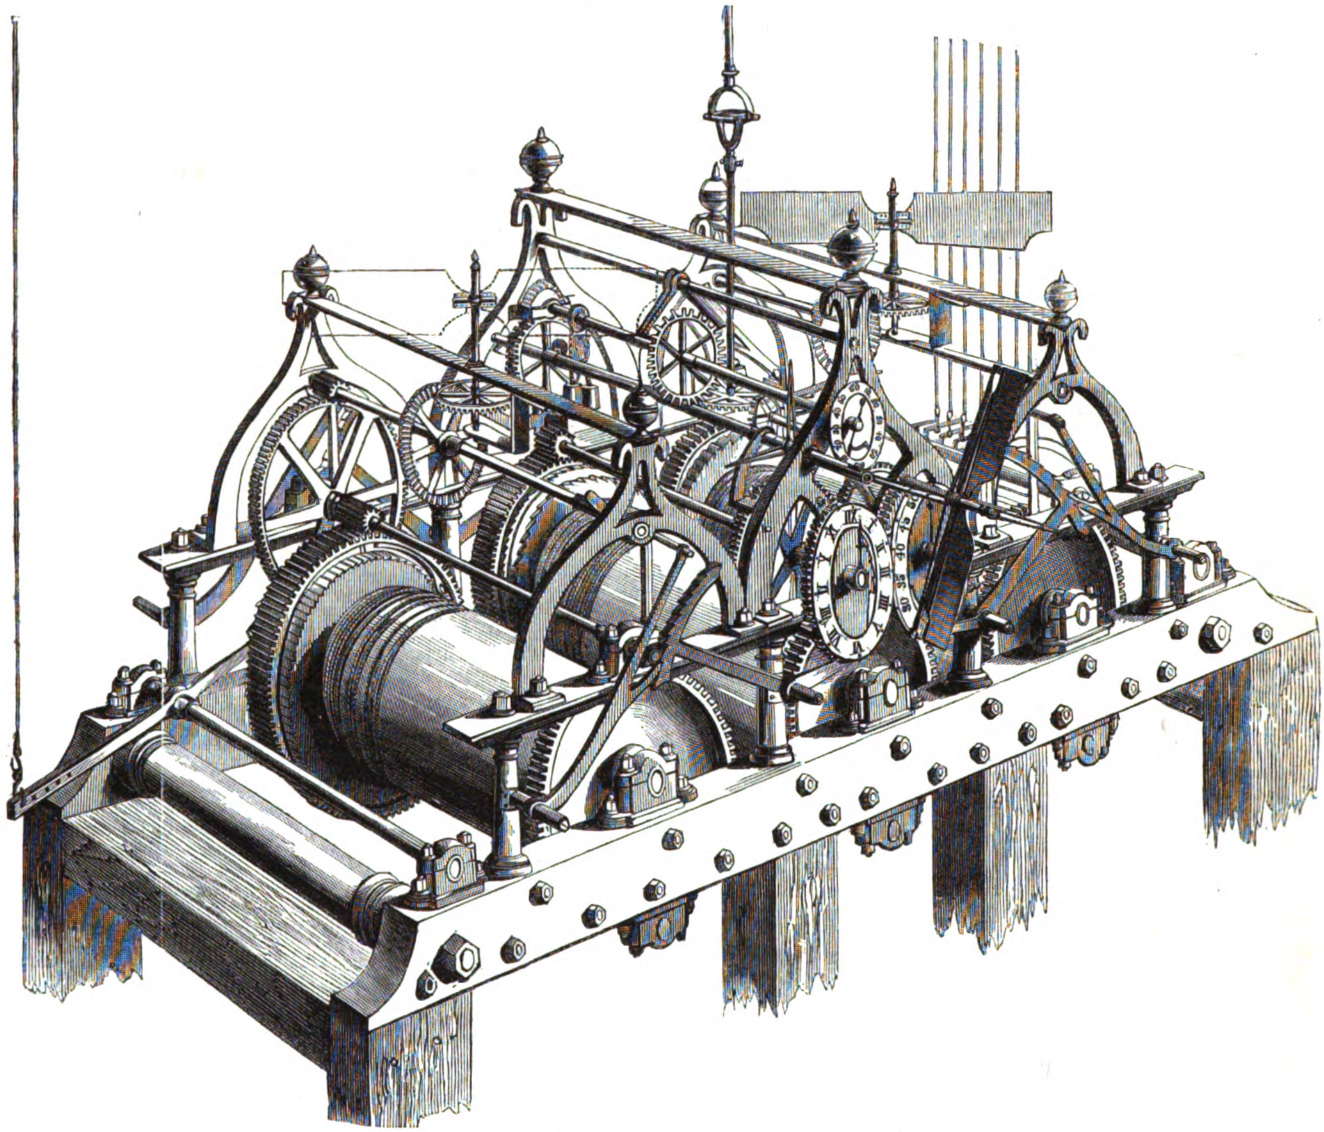
PHOTOGRAPHY ON MONT BLANC.

THE *Moniteur* contains an interesting description of an ascent of Mont Blanc, effected on the 11th ult. by M. Bisson, an eminent photographer, who had already performed the feat last year, but was desirous of completing his collection of views. His progress as far as the Grands-Mulets was not marked by any particular incident; he took various views from different points, and then proceeded to the Passage des Echelles, where he and his party crossed the ravines, some 300 feet deep, crawling on horizontal ladders one by one on their hands and feet. Their further progress to the Dôme de Goutté was, however, impeded by an unforeseen incident. A bridge of ice and snow, which had hitherto served as a passage to the Grand Plateau, had broken down, and they found a yawning abyss, from 45 to 155 feet in width, before them. No other passage seemed possible, and M. Bisson was on the point of giving up the adventure, when he was hailed by three of his men, who, unperceived, had sought a convenient place, and with their hatchets hewed out a path, by which they had succeeded in gaining the icy crest of the Mont Maudit. They soon descended the rocks on the other side, and threw ropes to their comrades, by which the luggage was hauled up. M. Bisson and the rest of the party followed the new but dangerous path, which brought them two hours sooner to the Grand Plateau. There new difficulties awaited them; they had to hew 800 steps, and ascend the side of the corridor, which in some places had an inclination of 50 degrees. On reaching the end of the corridor they were assailed by an icy cold wind. On arriving at the summit, after some further labour, M. Bisson found to his regret that the silver of his plates was crystallised, the temperature having suddenly fallen 10° Centigrade, although it was exactly noon. At 2 p.m. he descended from the summit, but visited it again on the 14th, and returned to Chamounix on the 15th without any further accident.

RAILWAY ACROSS THE PYRENEES.

ON August 21 the first railway train, drawn by locomotives, crossed the chain of the Cantabrian Pyrenees, over the northern division of the Tudela and Bilbao Railway, from the sea-port of Bilbao to the town of Miranda on the Ebro. The distance between these two towns is about sixty-six English miles, of which over forty are in ascending from the coast to the summit, 2,163ft. above the sea, being the lowest col or pass in the whole range of the Pyrenees. The average rate of ascent from the sea is 54ft. per mile; the maximum ascent is 76ft. The predominant curvature has a radius of only 300yds., and the curves are continually reversing. There are two points on the line at the entrance of the Basin of Ordima, distant only 600yds., measuring across the gorge or neck of the basin, which are fully 8¼ miles distant from each other in travelling along the line, and which differ 456ft. in level. The time taken in the transit is 2¾hrs.; and the scenery, as may be presumed from the locality and from the frequent change of direction on the line, is magnificent and varied. The last glimpse of the northern landscape the traveller has is over the Gujuli waterfall, and down to a depth of 400ft., to the bottom of the ravine into which it falls. The descent on the southern side is very gradual, the fall being on an average 24ft. per mile to the level of the Ebro. The total length of the railway is 155 miles—the length of the portion we have described being 66 miles, and the cost of these 66 miles more than 1,000,000*l.* sterling. The cost of the whole line, stations, rolling-stock, &c., was 2,500,000*l.*, all the capital being Spanish money, chiefly subscribed in Bilbao and its commercial connections. Not a share is held out of Spain or its colonies. A model of the passage of this railway across the Pyrenees is to be seen in the Engineering Court of the International Exhibition.

BENSON'S GREAT CLOCK IN THE EXHIBITION.



THE best time-keeper, when erected to its latitude with the necessary equation, is the sun-dial. But for obvious reasons we cannot have this time-keeper always at command, and men were driven to other shifts to measure day and night. The Romans had water-clocks for this purpose; the sand-glass was a time instrument, familiar to our own and other nations. But all such instruments were imperfect until the discovery of the pendulum, which, as everyone knows, depends for the regularity of its movements upon the law of gravity.

The discovery of the pendulum gave a certainty to the mechanical arrangements of time-measurers. It was now possible, after Galileo's discovery of the equal vibrations or pendulations of a body suspended by a string or otherwise from a fixed point, to measure time with greater accuracy than the best-constructed Clypsedron, hour-glass, or previous mechanical contrivance. But the best constructed clock gives only what is called *mean time*; that is, the clock exhibits 365 mean solar days, some odd hours and minutes, of 24 hours each, in equal parts. Consequently, the clock is sometimes in advance of true time, and sometimes is behind: hence the equation of time, and the directions given in almanacks to advance or retard the clock or watch in order to obtain true time.

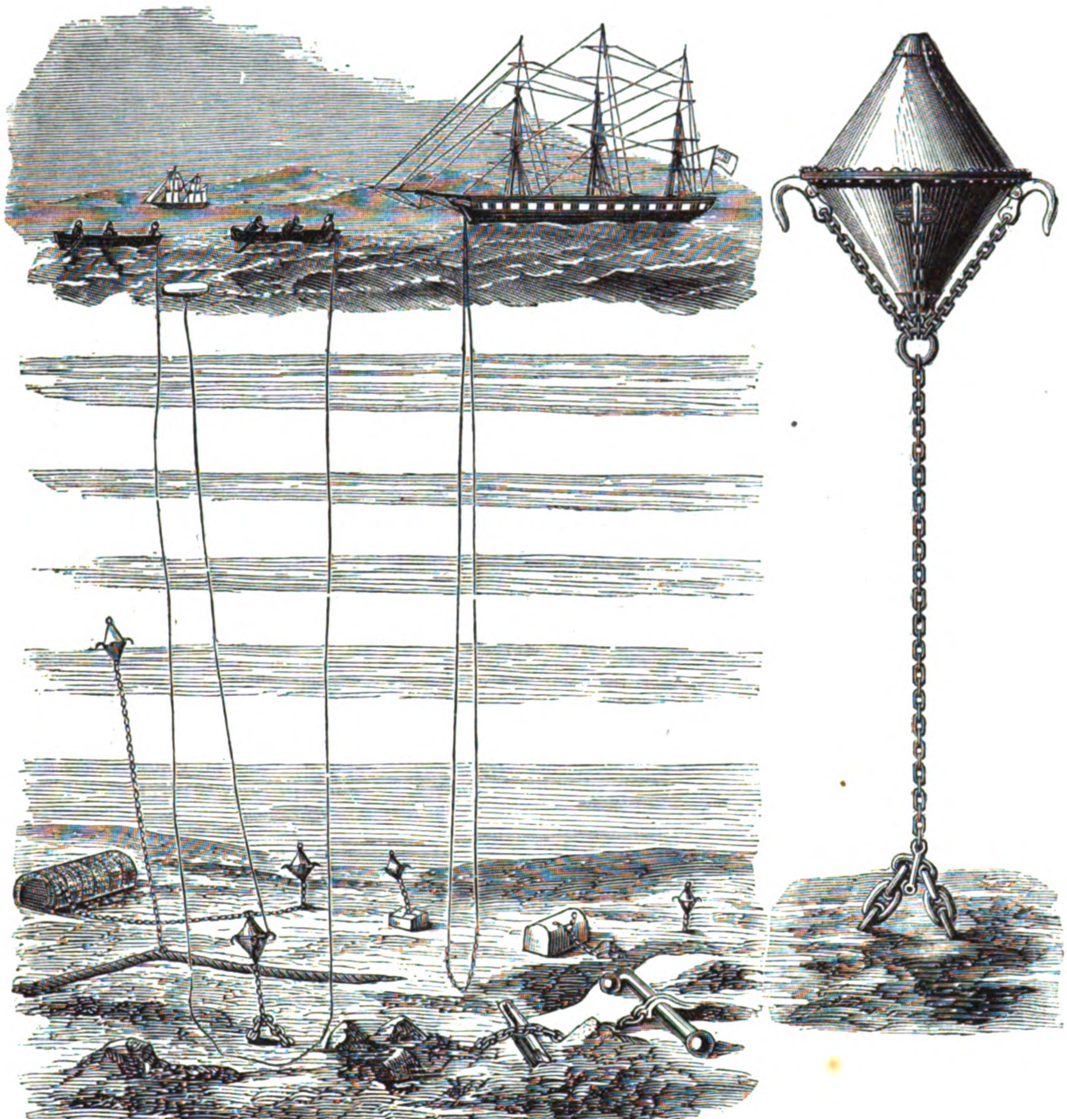
The pendulum clock is an advance upon the sun-dial, inasmuch as it does duty day and night, and, for ordinary purposes, does its duty well enough; but for the nice purposes of science, especially astronomical science, the pendulum cannot be entirely depended upon. The difference of a second may lead, in observing a heavenly body, to a mistake of tens of thousands of miles in distance. And so with the chronometer. This is not dependent on the pendulum, although the principle of the pendulum enters into it. Upon the accuracy of the chronometer depends the safety of the navigator and his crew. The variation of a few seconds might involve them in danger and shipwreck. We know to a mathematical nicety what ought to be the length of a pendulum vibrating seconds in any latitude. We can express in inches and decimals of an inch, extending to the moon and farther. The misfortune is that we cannot regulate the length of the pendulum without employing artifices: it has to be coaxed into doing duty, so to speak. The dull rod, like all of us, is affected by the heats of summer and the colds of winter. It is subject to temperature, and ever so nicely as we may measure its length in mean temperature, it is sometimes too long, at other times too short.

To keep the pendulum at a uniform length for a given latitude under every condition of temperature, has, therefore, been the grand attempt of mechanicians, and they have succeeded to such an extent that the year can now be measured out in equal portions so exactly, that there is scarcely the loss or gain of a few seconds at the close of it. The nearer we get mean time, the more valuable it is for all nautical and astronomical purposes. For example, a planet is due at a certain point in the heavens, according to true time; possibly, it has been retarded by the influence of other planets—disturbing forces have delayed it. As in the case of our own luminary, the moon, it keeps rather irregular hours It is by our knowledge of true time that we detect her shortcomings.

To describe the various artifices to keep the pendulum at its due length does not enter into our immediate purpose. The practical man has every detail at his finger's end; nor do we propose to ourselves the superfluous task of describing the machinery of a clock. There are, of course, different arrangements in the mechanism, but all depend on a common principle, and the end and object of every horological instrument is to tell mean time. Some of these instruments are better than others; some, too, are more ornamental and compact. The old-fashioned eight-day clock told the truth pretty well; his great-grandson tells the truth equally well, and is more of a dandy. Our fathers carried watches compared, for their bulk, to turnips. Watches are now made which a lady may carry on her finger-ring.

There are some most excellent specimens of horological contrivances in the International Exhibition. To name and describe them all would far exceed our limits. It is, perhaps, for the reason that large things attract rather than small, that so many people turn aside to view Benson's great piece of clockwork. It is certainly a marvellous achievement in clock making, both as regards the workmanship, and its capacity, under difficult circumstances, for time measuring. Its position in the Exhibition created a difficulty. We all know that the motive power of a clock is a weight, which ought to be near the machinery. In this case it is

TEMPLEMORE'S SUBMARINE RECOVERY BUOY.



200 feet from the machine, worked by pulleys under the floor. The frame of the clock is a wrought-iron bed of 9ft. 2in., with an upper bed of cast-iron 7ft. in length. The three principal driving-wheels are 2ft. in diameter, made of gun-metal 2 inches thick, and are a fine specimen of wheel cutting by machinery, the teeth of these as all the wheels being left untouched from the cutter. The liftings in the hour and quarter trains, are direct from the main power, thus securing accuracy and certainty of operation. One speciality in this large clock deserves notice. In case of wear, or derangement in any one of the large wheels, it may be removed without disturbing the others, as the gun-metal bosses are fitted in plummer blocks, being the first application of this convenience to clock-work. The length of the pendulum is 15 feet over all, and vibrates or sways once in two seconds. The weight of the oblong "bob" is 2 cwt., and the power of the clock nearly equal to that of Westminster. The efficacy of the machinery, and the time-keeping qualities of the clock, are due to the double lever *remontoir*, applied to Graham's dead-beat escapement, in which the mechanical arrangements are so disposed as to gain what is called "uniformity of pendulation." Hence, notwithstanding the difficulties under which the clock is placed, its error is within a second a day. The impulse of the motive-power does not swing the pendulum as women were wont to rock a cradle, but the motion is so uniform, that the arcs of pendulation are equal. The exactness and nicety of finish of the wheels would surprise anyone who learns that they are cut by machinery, without being in any way supplemented by hand-work. The ordinary observer notices the teeth of one wheel biting into those of another; he hears clickings, he sees parts disengage, revolve, and stand fast, and he is apt to look upon the clock as a complicated piece of machinery; but really the machinery or mechanism here is very simple, and, what is more to the purpose, it yields what we desire — a straightforward account. We ask "what's o'clock?" and the dial gives us the answer.

We say the dial; but in Benson's clock there are four dials, answering to the four sides of a church tower; and there is a fifth dial, which intimates the time of day to people in Cromwell Road. When we consider that this fifth dial is 70ft. above ground, and is worked by shafts distant from the machine some 300ft., we must admit the great achievement which has been here accomplished in clock-making.

We believe that Mr. Benson has a factory at Croydon, where all the heavier parts of his clock-work are cast and finished by machinery worked by steam power. The wheels are cast in gun-metal, the pinions are manufactured in steel. Here and at the workshops in the city, there are employed nearly 150 men. The number of watches produced at Ludgate Hill is something enormous, touching 15,000 yearly, manufactured on the most approved principle of division of labour, under the personal superintendence of the principal. The firm, as we understand, does not profess to make watches at the lowest price, but the best watches at the price; and from the magnitude of their business, and the necessity for more extensive premises, we may fairly judge that they have received the impress of public approval.

We would recommend the visitors to the Exhibition to do as we did — interrogate the attendant at this clock "trophy," whom they will find attentive and intelligent, and whose explanations will make an examination of this large clock both interesting and instructive.

TEMPLEMORE'S SUBMARINE RECOVERY BUOY.

Mr. Elton Templemore, connected with the Master Attendant's Office at Madras, has lately invented a Submarine Recovery Buoy, which has been patented in England, France, and other countries.

The patentee being engaged, during the year 1861, in recovering lost property, consisting principally of anchors and cables, in the Madras Roads, for the Madras Government, and being aware of the great expense which is necessarily incurred in all submarine operations, and the objections to diving on account of the danger to human life, and the limited

depth of water in which operations can be carried on, he has provided a plan by which for the future anchors and cables, and all submerged property, may be preserved from actual loss, and be recovered at any time without the aid of divers or any extraneous expense whatever.

The objections to the usual plan as applied to ships' moorings which the invention removes are these:—It is at times necessary, when a ship or other floating body is at anchor, to cut or slip the moorings, but before the moorings are let go, a rope and surface float is attached to the mooring chain near the hawser hole of the ship, or other floating body; the rope is of sufficient length to allow the buoy to float on the surface of the water. In this case, if the ship returns soon to her moorings, it is well and good, but if a longer time is allowed to elapse, she will find on her return that the buoy has disappeared, or what is invariably the case, the rope is in such a rotten state as to be completely useless for the purpose of raising the cable: the result of this is, the loss of the ship's moorings and the aid of the divers to seek it; but if it so happens that the anchorage ground is of soft yielding sand, the anchor and cable is irrecoverably lost, in consequence of its being buried out of sight under the surface of the ground; the same reasons hold good for jettisoned cargo.

In the case of lost property being submerged in a soft yielding sand, such as the Madras Roads, we have the subject in its most difficult bearing, the patentee assuming for granted that if successfully applied in this case it will overcome all difficulties eleswhere.

The practical experience of the patentee has shown him the insecurity of the present surface buoy, whether attached to a rope or chain. He therefore adopts a buoy to float under the surface of the water, which shall be free from all the objections with regard to the safety of the surface buoy. This buoy, which the patentee denominates a "submarine recovery buoy," is attached to a short piece of chain, by which it is shackled on to the ship's cable in the place of the ordinary buoy rope. The buoy has three hooks on its circumference, and, being of sufficient buoyancy to float itself, it will consequently remain floating near the surface of the anchorage ground, in a position suitable to be caught by the sweeping rope when required. For convenience and expedition in finding the exact spot, it may be attached to the ordinary rope and surface buoy; if this should disappear, the cable may still be recovered.

The patentee applies the buoy to all submerged property; if the articles are comparatively light, they may be recovered by the aid of the buoy fixed on the package itself; or, if heavy, a piece of chain of length sufficient to reach the surface of the water, and of sufficient strength to support the weight of the package, to the end of this chain the buoy is placed and let go, when it will remain in the position shown in the engraving.

Testimonials of its efficiency have been given by Sir William Denison, Governor of Madras, by the Master Attendant, and all the nautical authorities, as well as the journals of India, and by the undersigned:—

I can with pleasure endorse the opinions of the Superintendent of Marine on the general usefulness of Mr. Elton Templemore's submarine recovery buoy, and more especially for its invaluable use in saving anchors and cables slipped from in gales. It may also, while in soundings, be a certain means of saving treasure from the capture of an enemy.

H. D. E. Dalrymple,
Master Attendant and Conservator of the Port of Madras.

Having examined Mr. Elton Templemore's submarine recovery buoy, I have the pleasure to record my opinion of it as an invention likely to be useful in the recovery of articles from the bottom of harbours and roadsteads, but more particularly of anchors and cables, which may have parted or may have been slipped in soft mud or shifting sand.—(From J. J. Franklin, Esq., Superintendent of Marine, Madras, May 19, 1862.)

Mr. Lynall Thomas has induced the War Department to give him permission, at the cost of about 2,000*l.*, to manufacture a gun of 16 tons weight, on his principle, at the Royal Arsenal, Woolwich.

THEORETICAL FORMULÆ FOR THE MOVEMENT OF AIR IN CONDUIT-PIPES.

By Gen. A. Morin,

Academy of Sciences of Paris.*

(Concluded from p. 128.)

Introduction of the External Air by the Heating Apparatus.—By examining in a theoretical point of view the conditions of the introduction of air by hot-water apparatus, into the wards of the Hospital Lariboisière, and introducing the data from observation into the formulæ obtained, we obtain the following results:—

The temperature of the air furnished by the stoves being respectively

32°, 26°, 22°, 21° (Cent.);

the values of the velocity of inflow of the air into the wards were found

	mèt.	mèt.	mèt.	mèt.	
by the formulæ,	1·29,	1·21,	1·18,	1·17,	per second.
by experiment,	1·14,	1·04,	1·13,	1·15,	„

If we take into consideration the uncertainty which may exist as to the dimensions, and especially the obstacles sometimes inevitable, such as mere spider webs, which are too often found in the conduits and stove-pipes, it will be without doubt admitted that the accordance of the formula with experiment is at least sufficiently satisfactory to allow of its being taken, with some latitude, for an approximative rule for the arrangement and proportions to the apparatus in analogous cases.

The formula which is applicable to the cases just mentioned shows this remarkable circumstance, that the temperature of the air which traverses the stoves, which, it may be remarked, is very moderate, has much less influence over the velocity of that air during heating than the air of the ward at its normal temperature. This is the consequence of the slight height given to the stoves.

This result shows the necessity of giving to the stoves as great a height as possible.

As to the introduction of the air in summer, the same formula shows the insufficiency of the orifices offered by the stoves, and I recall in my memoir the easy means of remedying this, which I had already noted on other occasions.

Application to the Apparatus for Ventilation by Draught of the Hospital Lariboisière.—The work which I present to the Academy contains, moreover, a complete application of the principles exposed to the effects of ventilation which are produced in the wings of the Hospital Lariboisière, which are ventilated by draught. It is known that each one of these wings has three stories, each composed of a ward containing thirty-two beds, and a small chamber of two beds. The vitiated air is drawn off from the wards of each story by nineteen discharge-chimneys, which unite under the roof at the base of a general discharge-chimney, in which is the reservoir of hot water intended to stimulate and regulate the draught.

Taking into consideration all the circumstances of the movement of the air in these complex circulations, the mean velocity of discharge in the general chimney may be calculated, and we thus obtain a formula into which, introducing the data of observation of five experiments made, the first two in the winter season, when the temperatures of the external air were — 5° and 2° (Cent.), and the last three in summer, at an external temperature of 18·3° (Cent.), then, comparing the results of calculation with those of direct experiment, we reach the following results:—

	Temperatures of the air			Velocity in chimney	
	External	Wards	Chimney	Formula	Experiment
	Cent.	Cent.	Cent.	Mètres	Mètres
Jan. 11, 1861	−5°	15°	19°	1·465	1·39
„ 20, 1861	−2	15	18	1·334	1·24
Aug. 31, 1861	18·3	21·5	38·1	0·949	0·95
		22	41·2	1·051	0·94
		22	40·9	1·041	1·07

The examination of these results shows that, even for cases as complex as those here considered, the principle of living-forces or work, leads to formulæ which accord as well with practice as could be expected in such applications.

This comparison also shows the enormous influence exerted by the losses of force and resistance of the walls, upon the effects which the difference of temperatures would naturally produce. These two causes conjoined reduce the velocity of discharge in the chimneys to about 0·33 of what it would have been if they could have been avoided; which shows the importance of all the arrangements which diminish these effects, which, however, cannot be entirely got rid of.

Finally, the application of which we have discussed the results, shows that in the denominator of the fraction placed under the radical of the expression for the velocity, the term which depends on the loss of living-force enters for 0·864 of its value, and that arising from the resistance of the walls to 0·136 only; which shows the importance of avoiding complicated circulations.

Application of the Discussion of the Experiments made at the Conservatoire des Arts et Metiers.—Besides the application of the theoretic formulæ to the practical apparatus for the circulation of air, others were made for the discussion of the direct experiments which M. Tresca and myself had executed during an investigation into the chimneys of steam engines.

These experiments, which we propose to resume immediately, were tried under three different conditions:—

1st. Upon a zinc chimney of 0·24 m. diameter and 11 mètres high, entirely open at its two extremities, and under which were successively lighted one, two, three, and four gas-lights.

2d. Upon the same chimney surmounted by an elongated conical ajutage, of which the upper opening was made to vary by cutting it off, and giving to it successively the diameters 0·10 m.; 0·14; 0·18; 0·21.

3d. Upon a cylindrical chimney of 0·25m. diameter, surmounting a very conical base placed over a chandelier of 34 burners, and terminated by a conical ajutage, the edges of which were inclined 45° to the axis, and which had successively diameters of 0·210; 0·200; 0·180; 0·158; 0·182; 0·115; and 0·080 mètres.

In all these experiments were observed the external and internal temperature range and the velocity of the air in the pipe, or at its upper termination; the results of these observations were compared with the theoretical formula

$$V_1 = \sqrt{\frac{2\,g\,a\,H\,(t - T)}{1 + \left(\frac{1}{m} - 1\right)^2 + \left(\frac{m_1 A_1}{A}\right) + \frac{2 8\,L}{D}\beta}}$$

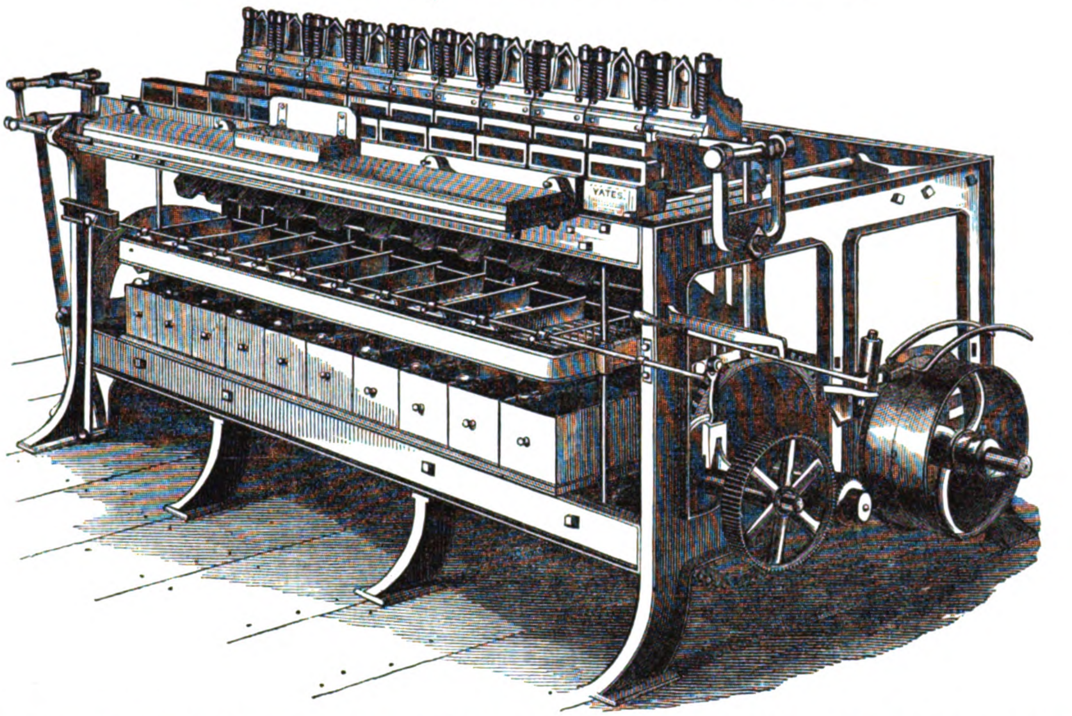
This comparison shows that, in these three series of experiments, the results of observation follow, as in the preceding cases, the law of the formula. But as this formula does not take into consideration the losses of heat produced by the thin metallic walls of these chimneys, it is necessary in every case to apply to it a coefficient of reduction, the mean value of which differs very little from 0·8; which shows within what limits the exactness of the theory explains the natural effects.

If the difficulties of the question and the uncertainties of the observations are taken into consideration, and if it be remembered that the greater part of the theories of applied mechanics, and especially that of water-wheels, often do not offer so regular an agreement with observation, it will be no doubt admitted that the formula which we have reached may be employed in the study of ventilation with as great a degree of exactness as the requirements of the art demand.

Graphic Representation of the Formulæ and of the Experiments.—When we remark, moreover, that for each peculiar arrangement in which the material data remain the same, and for a determinate mean external temperature, the preceding formula may be put under the form $V^2 = N\,(t - T)$; which is the equation of a parabola, or, more simply, that of a straight line passing through the origin of the coordinates, the abscissæ of which are the difference of temperatures $(t - T)$, and the ordinates, the squares of the velocities.

* Translated for the Journal of the Franklin Institute, U.S.

YATES'S BRISTLE-ASSORTING MACHINE.



It may be concluded that, as this straight line may be determined by means of a single well-made observation, we shall thus have, by graphic construction, all the velocities corresponding to the different temperatures, and reciprocally; which conclusion will permit us to solve, without calculation, several interesting questions of application.

Conclusion. — It is seen by this analysis of the researches which I have the honour to present to the Academy, that the application of the principle of living-forces, or of the transmission of work to the movement of the air in chimneys, or apparatus for ventilation by draught, leads to formulæ which, in very different cases, are found in accordance with experiment. These verifications are relative: —

1st. To the practical formula which observation had led M. Guerin to adopt for ordinary ventilation chimneys.

2nd. To the introduction of hot air by the stoves of the wings of the Hospital Lariboisière, heated by the circulation of water.

3rd. To the ventilation in general of these wings, both in winter and summer.

4th. To three sets of direct experiments made on metallic chimneys.

From this general accordance of the formulæ with the results of experiment, it appears, therefore, allowable to infer that we may, without fear of notable error, calculate beforehand the effect of different systems of ventilation by draught, and deduce laws which will be useful in building.—*Comptes-Rendus de l'Académie des Sciences*, February 24, 1862.

YATES'S BRISTLE-ASSORTING MACHINE.

One of the most interesting and ingenious pieces of mechanism in the Western Annexe of the International Exhibition is a machine invented by Mr. W. S. Yates for assorting bristles. It is generally at work, and invariably surrounded by an enquiring crowd of spectators. There is scarcely a machine in the Annexe which has secured more attention, or which deserves more. Having desired Mr. Yates to send us a description of the machine to accompany the illustration, he sent us the following:—

Sir, — In order that you may more perfectly understand the relation of the bristle-assorting machine to the brush trade, I may observe that bristles as imported are in a mixed state, and require to be separated into lengths or sizes, and sometimes into diameters with regard to the strongest bristles.

Before the introduction of this machine, it was done exclusively by hand, the workman holding the bristles in one hand, and with the finger and thumb of the other dividing them as required, requiring long practice to enable him to do this efficiently—a most tedious and unprofitable process, and exhibited the trade in a state far behind the mechanical requirements of the age.

A visit to the last Exhibition, 1851, caused me to ask what could be done for the brush trade (that being the business with which I was originally connected)? I saw that there was great need of better tools; that, as a trade, it presented some of the most difficult problems, in the solving of which, years of study and experiment would be required, but, when accomplished, would be to the advantage of the business, economising the cost of production, enlarging the market, and enabling the workman to obtain better and more constant employment. I determined to try what I could do, and began with the beginning—the dressing of bristles, and, like too many young mechanics, attempted too much. Experience soon made me wiser; and, after three years of close application, I succeeded in trying my first machine. I had the pleasure of seeing it separate the bristles into ¼in. lengths, and deposit them in appropriate receptacles. In order fully to test the machine, I began to dress bristles for the trade in my native town, and charging the men's price, but allowing a discount of 10 or 15 per cent., according to the amount of work required. By so doing, I was enabled to test the working capabilities of the machine in relation to almost all kinds of bristles, and, in 1856, obtained testimonials from the trade, in Leeds as well as other places.

I had great difficulty in carrying out my purpose, the men declining to work the machine, though I offered to guarantee that, individually, they should not earn less wages. I was compelled to teach strangers the entire process of bristle dressing, and also the use of the machine. As a body, the union men still refuse to work the machines.

About three years ago I exhibited a small machine in Whitechapel, and obtained the written approval of many manufacturers, but only one order. Since then I have had the satisfaction o sending out one of my largest machines to Russia, the first, I believe, ever sent there or elsewhere. It has been in operation rather more than two years, and has obtained entire approval.

The machine at the International Exhibition is the fourth, and embodies the experience of many years of study and experiment, and separates bristles into ten lengths, varying from each other ¼in. It can also be adapted, if required, to separate these lengths into their respective diameters.

To do this, a series of nippers, arranged side by side on a rocking frame, are made to open and close by the rotation of cams, suitably constructed for that purpose, operating through rods having at one end studs and bowls working in the grooves of the cams, and steadied by V slides, the other end being attached to the nippers; the frame to which the nippers are secured is then made to move backwards and forwards by crank arms.

In front of the nippers are situated two long V slides, containing a series of gill-combs secured to sliding carriages, which, when charged with bristles, are made to pass successively before the nippers, and each nipper, being a little in advance of the other, takes hold of the bristles within reach; the rocking frame, receding, draws out the lengths thus secured; the jaws of the nippers then open, and deliver the bristles on to a number of tin carriages, which, as the frame moves forward to its original position, gives a separate and distinct motion to these carriages, gently disposing the bristles thus separated upon a number of corrugated tables, which are afterwards raked off by the rakes attached to a long rod in front of the machine, a suitable motion being imparted by its connection with a slotted lever, and also a shorter one, with pin and bowl, working in a cam groove on a wheel attached to the main shaft of the machine.

The bristles thus find their way into the chambers connected with the before-mentioned corrugated tables, which, when full, are opened, and the bristles slide down in a body into the boxes below, and are ready to be removed.

An intermittent motion is communicated to the gill-combs and carriages by a twisted wheel attached to the preceding end of the main shaft of the machine; in this wheel a suitable cam-groove is made, imparting an oscillatory motion to a lever arm; to the upper end of this lever is connected a rod, which is carried through the end of the frame

underneath the slides containing the holders, and also through the frame at the opposite end; and at each end a paul is attached, which, acting against the ends of the carriages at proper times, causes them to move forward a stage; they are thus in succession made to pass before the nippers.

To prevent the need of an attendant at each end of the slides, one to insert the holders containing the bristles, and the other to receive the same when empty, another motion has been attached to the machine; two little carriages are made to wait upon each holder as they are in rotation pushed out of the long V slides before named, and are then conveyed to the opposite line of rails, and remain opposite to the openings of the same until the paul has had time to propel the holders out of this transfer carriage into the long slide or rails: in this way a constant change of position is secured, and the machine almost made entirely self-acting. With this addition, two boys would be able to dress as many bristles as would require at least eight men by the old process. The combs containing the bristles are caused to stand before the nippers sufficiently long to secure the whole of each length being properly drawn out; the number of draws to each length being governed by change wheels in communication with the main shaft of the machine. W. S. YATES.

PREVENTION OF COLLIERY ACCIDENTS.

AT the close of the late session of Parliament an Act was passed to amend the law relating to coal mines. This Act provides for every mine two shafts or outlets. It is now enacted that it shall not be lawful for the owner of a new mine, and after January 1, 1865, it shall not be lawful for the owner of an existing mine, to employ any person in working within such mine, or to permit any person to be in such mine for the purpose of working therein, unless there are in communication with every seam of the mine, for the time being, at least two shafts or outlets at work, separated by natural strata of not less than 10 feet in breadth, by which shafts or outlets distinct means of ingress and egress are available to the persons employed in the mine; but it shall not be necessary for the two shafts or outlets to belong to the same mine, if the persons therein employed have available means of ingress and egress by not less than two shafts or outlets, one or more of which may belong to another mine. The provision is not to apply to opening a new mine for the purpose of searching for or moving minerals, or to any working for the purpose of making a communication between two or more shafts, so long as not more than 20 persons are employed at any one time in the new mine or working. If the owner of an existing mine object to the Secretary of State that, by reason of the nature of the mine, or from other special circumstances, he cannot comply with the new law, a reference is to be made to arbitration, and an extension of time may be granted, or the owner required to make two outlets for the safety of the workpeople or otherwise. Further, the Act provides a summary proceeding, by way of injunction, to restrain the owner working a mine to which there are not two shafts or outlets. Any of the courts of equity or common law may, upon the application of the Attorney-General, acting on behalf of the Secretary of State, prohibit by injunction the working of any mine in which any person is employed in working or is permitted to be for the purpose of working in contravention of the provisions of the Act, and may award costs; but the section is to be without prejudice to any other remedy permitted by law for enforcing the Act. No person is to be precluded by any agreement made before the passing of the Act from doing anything that may be necessary for providing an additional shaft or outlet to a mine where the same is now required, nor be liable under any agreement to any penalty or forfeiture for doing what may be necessary to comply with the present Act. The powers now given are to be construed with the Principal Act; and it is fervently to be hoped that, by the exercise of the authority now vested in the Government, there will be no further sacrifice of human life by accidents in coal mines.

Correspondence.

THE TRUE PRINCIPLES OF AIR NAVIGATION EXPLAINED.

TO THE EDITOR OF "THE MECHANICS' MAGAZINE."

SIR,—I regret to observe that Mr. Quartermain has resumed the discussion of this subject with views not very greatly improved, and upon one point precisely the same as they were on the former occasion, when I took the liberty of explaining to him that they involved the principle of perpetual motion. The point to which I allude does not end in that absurdity, but it is a serious error, and it lies at the very foundation of his project. In bringing forward the elasticity of air as affording the resistance to compression, on which propelling efforts in flying, or in balloon directing, are to act, and in ignoring the mobility of air which would be destructive of his hypothesis, he fundamentally errs in the physics of his subject. He is not singular in this sort of error. Even the most able of mathematicians, consummately skilful in handling the instruments for forming didactive trains of thought, do sometimes egregiously fail in reference to the practical character of their conclusions, because not apt at inductive investigation, and not disciplined to its peculiar order and habits of thinking, they forego correct physical conceptions of their subject in favour of imaginary modes of acting. The celebrated Euler, for instance, was as puerile and impotent in physics as he was powerful in mathematical analysis. He found it easier, and more manageable, too, for subsequent treatment, to feign things out of his own head, than to go to nature for instruction and ideas. Mr. Quartermain, therefore, finds himself in good company; but as similar errors require similar treatment, I propose to send him to experiment and observation for the correction of his opinions.

Let him take some light material in his hand, say a foot square of pasteboard, and force it against the air with the greatest velocity he can give to it, when he will convince himself, roughly yet quite sufficiently, by the very slight resistance he will perceive, that a wing surface of only 41¾in., with a velocity of only 3½ft. per second, will never raise a bird weighing rather more than 1¾lb.; and yet this is the conclusion, avowedly, to which his theoretical phantasy brings him. To be more precise, I refer him to Hutton's table of experiments, from which he may ascertain that the air will oppose to such a wing surface a resistance of about one-tenth of an ounce! Again, let him check suddenly the motion of his board of 144in. surface, and he will not perceive the slightest elastic rebound from the compression of air; but if he will take an air syringe, even of only one inch area, close the exit-valve and send down the piston with the same velocity, he will perceive that compression and elasticity are ready enough to give evidence of their reality, by producing a powerful resiliance when practically they do exist; and that restraint, or non-restraint, upon the mobility of the air in the two cases makes all the difference. Still, it is possible that compression and elasticity come into play with very low velocities of a moving body, but the fact is not sensible, and can have practical effect only in the very great velocities of military projectiles.

Mr. Quartermain's calculation of the resistance which air opposes to a wing surface of 41¾in., urged with a velocity of 45½ft. per second, though based on correct principles, and therefore oppugned by him as producing incredible results, is not accurate, because he takes for datum a plane surface of that dimension. The amount of resistance should be doubled, because of the concavity described by him of the under surface of the wing, and therefore the velocity which he assigns to it as necessary should be reduced in the ratio of 1·414 to 1. The calculation is faulty again, in taking the average velocity and resistance of the wing, instead of the mean of the resistances, due to the squares of the velocities of the respective portions of it. He also assumes that the upward and downward strokes of the wing are equally timed, which I believe is not the fact, at least in all cases, particularly in the slower motions. Thus the 50 strokes per second, which he thinks so incredible, could be reduced to 25, and yet be equally efficient if the velocity of the down strokes were increased in the ratio of 1 to 1·414. The time saved would be given to slight pauses between the strokes, and to a slower movement of the upward strokes. This number (25) being further reduced in the ratio of 1·414 to 1 on account of the concave surface of the wing, namely, to 17, and again reduced for the other reason mentioned, we should arrive at a number of strokes per second not at all extraordinary. At any rate, be what they will, and however we may stumble in calculation, a resistance of the air proportional to the square of the velocity, or a little beyond it, and a series of absolute resistances determined by experiments, and which, perhaps, for sundry reasons, are somewhat greater in fact than are given in Hutton's tables, especially for the higher velocities beyond their range, but deducible from them—are the only legitimate data on which projects can be founded.

Yours, &c.,
BENJ. CHEVERTON.

Sept. 1.

Gossip.

Dr. Robert Angus Smith, of Manchester, writes to us as follows:—"The experiments at Liverpool on petroleum, spoken of by you two weeks ago, are, no doubt, very valuable, as a portion of a number to be made, but if taken by themselves they seem to establish nothing. You did not inform us of the evaporating point of the oils, and we do not, therefore, know definitely on what substances the experiments were made. If the oil burnt on the cold ground, it must have been a very dangerous specimen. The absence of very violent explosion is not remarkable. Explosion takes place when the vapour is mixed with air, and this occurs chiefly when there is evaporation in an enclosed space. Experiments made in the open air do not necessarily cause explosions. The two great facts to be remembered respecting the volatile petroleum are: 1st. That the vapour rising at the ordinary temperatures ignites readily, and when mixed with air explodes. It mixes with air like gas, and in this lies its hidden danger. 2nd. When water is thrown on the oil, the oil floats on the water and still burns; whereas, spirits mix with water, become diluted, and cease to burn. Having made many trials of these oils, I thought it well to guard against some of the conclusions drawn from the experiments alluded."

The iron trade of South Staffordshire continues to show some degree of improvement. The demand for ship-building plates is good, and there is a fair supply of orders for sheets, which, however, it is feared, may prove only temporary. Common bars are being sold at a very low rate by the second-class makers; but even for this kind of iron there are decidedly more orders than there were. The fine weather has a beneficial effect; and if it continue, we may hope for a slight improvement in the trade, though not a great one, while the American war and the consequent depression of the cotton districts, continues. The works at Wednesbury, engaged in the manufacture of railway wheels and axles, are rather better supplied with orders than they were. The pig iron manufacturers are again seeking an advance of prices. As yet buyers set their faces against any such augmentation, although no doubt the prices of pigs are low; but this is equally true of finished iron.

On Wednesday week a granite column, 31ft. long, and weighing nearly 35 tons, was brought from one of the quarries of Messrs. W. & J. Freeman, to their polishing works, Penryn, Cornwall. It was drawn by a team of forty horses, assisted by two hundred workmen, and attracted a large number of spectators. This block will form the shaft of a memorial column to the late Duke of Wellington, to be erected at Strathfieldsaye, by his son, the present Duke, who has intrusted Messrs. Freeman with the execution of the work. The design is by Marochetti, and includes a granite pedestal weighing over 40 tons, supported on steps of large dimensions. There will also be elaborate mouldings in polished granite, the whole being surmounted by a bronze statue of the late duke, by Baron Marochetti.

In July 1860 we exported goods worth 12,522,698*l.*; in July last year these figures dropped to 10,094,260*l.* In July this year they rose to 12,131,801*l.*, thus showing that the American war does not materially affect our prosperity. We export more cotton goods than anything else, next come woollen goods, and then follow our iron and steel manufactures. We do a larger trade in pickles than in furniture, more in butter than in books. Our horses seemed to be prized abroad, but not so much as our hats. Our leather is more sought after than our rifles, our gunpowder, or our bayonets, even in these days of war. We export considerable quantities of fish, beer, and bacon. In productions of art and articles of taste we import rather more than we export.

The works at Lossiemouth, N.B., for effecting the drainage of the Loch of Spynie, are now being carried on with energy. A strong cofferdam has been constructed to keep out the flood tide, and a turning sluice made at the bottom of it. This will enable the excavations to be made deeper for the foundation of the stone bridge, that is to be built within the cofferdam across the canal, a little above the high water mark. The bridge is to be founded upon piles and concrete. A few yards above the bridge four large self-acting sluices are to be placed on a flooring of stone.

We are given to understand that there is a good deal of activity just now in the Dolgelly district of Merionethshire, and expectation is on tiptoe about this auriferous region. St. David, at Clogau, has inspired the people with the conviction that gold is to be found everywhere in the neighbourhood, and gold can be washed from the soil in very fine dust on the top of Berthwyllyd Mountain, Cae Mawr, and Cefn Coch. Gold is also found in quartz at Cwmheisian; in lead at Tydyndwadis; in the alluvial on the bank of the Mawddach river; at North Dolfrwynog and West Dolfrwynog; again, attached to the roots of moss on the Tyddyndwaddis side, not far from the beautiful waterfall of Pistil-y-cain. It was found very rich in quartz and galena, at the Old Dolfrwynog, and has been discovered in other localities. Fine specimens were also found in quartz at the Glasdir Mine. A quartz vein, with visible gold in it, has recently been discovered at Ganthllwyd, about seven miles on the Maentwrog road from Dolgelly. The Cambrian Mine, on the Barmouth road, is producing rich gold in blende; and the neighbouring mine of Garthgell expects it shortly on the same lode on the opposite side of the river. The Prince of Wales Mine last week produced nearly 2lb. of gold from 7cwt. of ore; and St. David gave its weekly contribution of 160oz., 140oz. of which was obtained from 7½cwts.

Messrs. Brocklebank, of Cumberland, have launched a splendid new ship, 803 tons new, and 900 tons old measurement. Her length between the perpendiculars is 192ft., breadth of beam 32ft., and depth of hold 21ft. 6in. She is flush built, is to be ship-rigged, and will have two of Cunningham's patent reefing topsails main and fore. She is sister ship to the Comorin and Arracan, the latter of which made the passage to Calcutta in 84 days. The same day the Messrs. Brocklebank had the keel and part of the frame of a 660 ton ship cut out, ready for laying on the Burdwan's blocks, and a fine first-class coaster, now approaching completion in their yard, is expected to be launched next month.

The *Cumberland Pacquet* says: "We are glad to find that Mr. John Kennedy, the author of the beautiful model that has been attracting so much public attention and interest for the last few weeks, has resolved upon testing the Nautilus war screw, which he proposes to introduce for the double purpose of propulsion and steerage. Machinery adapted for the testing of the screw has been completed, and we believe the experiments are intended to be made in the Harbour here on Thursday (yesterday), when there will doubtless be a large assemblage to witness the proceedings. We may add that since we last adverted to the subject, Mr. Kennedy has been closely engaged in overcoming some difficulties that presented themselves against the practicability of his newly-designed motive power, which he has now entirely overcome, and his invention promises to be attended with the most complete success."

The Calcutta and South-Eastern Railway was opened for passenger traffic in January last. Other works of importance are being executed in India. The Piallee bridge is rapidly approaching completion, although the execution of the work has been delayed in consequence of the scarcity of labour. The Eastern Bengal Railway, and the two great iron bridges across the rivers Gohamuttee and Coomar, are nearly finished.

The *Court Journal* announces that the Prince of Wales has given directions for re-embellishing and fitting-up the Adelaide frigate, on Virginia Water, in a style of elegance similar to the Victoria and Albert yacht. The Belvidere is also being fitted up as a residence for Commander Welch. This fort was originally built by the old Duke of Cumberland, brother to George III., but, after his death, was suffered to go into decay, till George IV. had it put into its present state of repair.

At a recent meeting of the Academy of Sciences, some observations were made on a specimen of clay, sent M. Marcel de Serres, on which there was produced, by artificial means, impressions of rain similar to those of the antediluvian world which are described by geologists.

The arrangements for the formation of the fleet of the future for China are being pushed forward as rapidly as possible by Mr. Lay, who represents the Chinese Government in this country, and Captain Sherard Osborn, C.B., who takes the command-in-chief. The Amoy screw gunboat, late the Jasper, and purchased from the Admiralty, is under orders to leave Portsmouth, under the command of Commander Salwell, for the Victoria docks, where the squadron will assemble and complete their outfit prior to sailing for China. Captains Sherard Osborn, Burgoyne, and Allen Young will proceed at once to Devonport to take possession of the Mohawk and Africa screw gunvessels, which have been placed at the disposal of the Chinese Government by the Admiralty. The Africa is a new vessel fitted to carry four guns, has a tonnage of 669 tons, and is fitted with screw engines of 150-horse power, nominal. The Mohawk has been in commission, but is a very fine vessel of her class. She is of 670 tons, fitted like the Africa to carry four guns, and has seven engines of 200-horse power. The purchase of the Nimrod screw vessel at Portsmouth has been declined by Mr. Lay and Captain Osborn, owing to her defects having been found to be far more extensive than had been anticipated. Mr. John White, of the Medina dock and building-yard at West Cowes, has been commissioned to build for Captain Osborn's fleet a paddle wheel steamer of the Psyche class, but of rather larger tonnage and horse power of engines. She is estimated to realise a speed of 18 knots per hour. Messrs. Laird, of Birkenhead, have also been commissioned to build two improved gunvessels, their sides to be covered with shell-proof armour plating.—*Times.*

A chambered tumulus, which was discovered a short time since in a partially-ploughed field at Nympsfield, Gloucestershire, was opened on Saturday, under the superintendence of some gentlemen connected with the Cotteswold Naturalists' Club. The longitudinal area of the sepulchre was defined by eight massive unwrought slabs of great oolite, laid in pairs, and varying from three to four feet in width. The entrance was at the east end. It became obvious, from the distvrbed state of the interior, that at some remote period the barrow had been broken into and plundered. A great number of bones of both sexes were strewn around, indicating that the tumulus was the burying vault of some family or tribe, and not, as was at first suspected, the sepulchre of heroes. Altogether thirty-four femora were discovered, together with a skull, 22in. in circumference, some jaw bones, several of which evidently belonged to children, a piece of half-burnt pottery, some flint flakes, a boar's tusk, some pigs' bones and incisor teeth. The whole of these objects were removed, and will be deposited, *pro tempore*, in the museum of the Agricultural College at Cirencester, where they will be open to inspection.

The special jury appointed to decide the dispute between the Government and Mr. Thistlethwayte, in relation to the land for the erection of Portsdown Forts, has awarded that 95,200*l*. be given to that gentleman. His claim was considerably in advance of the sum awarded. Mr. Montagu Smith, Q.C., presided as assessor.

The next meeting of the British Association for the Advancement of Science will be held at Cambridge, commencing on October 1. The Rev. R. Willis, M.A., F.R.S., will preside, and the reception room will be at the Town Hall.

The drift gallery of the Attock Tunnel, India, is 1,505·5ft. in length. It is said that this gallery is experimental, and that on its successful issue, which is now almost certain, the main gallery, 44ft. lower, will be commenced. The east shaft of this latter will be 200ft. from the surface, and the west shaft 129ft. The bed of the river will be 75ft. from the main shaft, at the nearest point, and 109ft. at the most distant.

A scientific balloon ascent is shortly to be made under the auspices of the Berlin Academy, after the plan of Mr. Glaisher's successful attempts, which have created considerable interest among scientific societies abroad.

A fine collection of objects, collected by M. E. Renard during his sojourn in Phœnicia, has recently been deposited in the Palais de l'Industrie, Paris. This comprises a large number of jewels, with gold and precious stones; works in glass, clay, bronze, and marble; no less than sixteen large sarcophagi of white marble, or alabaster; and a great mosaic, more than 30ft. long and 20ft. wide. This has the usual border of foliage, but of unusual width; it is divided into sections of oblong form, containing heads of men or divinities, and is supposed to be of the Roman period.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 438, 441.

BOILERS AND THEIR FURNACES, &c., 406, 423.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 411, 416, 433.

SHIPS AND BOATS, including their fittings, 400, 410.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 427, 434.

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, *None.*

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 408, 414, 419, 420, 425, 437, 450.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 403.

LIGHTING, HEATING, AND VENTILATING, 439, 444.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 404, 415, 426, 446, 448.

METALS, including apparatus for their manufacture, *None.*

CHEMISTRY AND PHOTOGRAPHY, &c., 429, 443, 449.

ELECTRICAL APPARATUS, &c., 413.

WARFARE, &c., 409, 432.

LETTER-PRESS PRINTING, &c., *None.*

MISCELLANEOUS, 401, 402, 405, 407, 412, 417, 418, 421, 422, 424, 428, 430, 431, 435, 436, 440, 442, 445, 447.

400. J. H. JOHNSON. *Improvements in machinery or apparatus for propelling ships and boats.* (A communication.) Dated Feb. 14, 1862.

This consists in the use of two shafts or strong rods sliding longitudinally to and fro in suitable bearings, placed near the bottom of the ship or vessel, and inside the same, such shafts or rods being parallel with each other and with the kelson, one being placed on each side thereof, and the ends of the two passing out through stuffing boxes at the stern, situate respectively on each side of the dead wood. Near the outer extremities of each of these shafts or rods is fitted a pair of hinged blades or wings, carried on a block secured to the propeller shaft, and so arranged as to be capable of expanding when pushed forward by the resistance of the water, and of closing again by the same resistance when drawn back, both propellers being wholly or partially submerged. In combination with each propeller are two movable stops or cross arms, made capable of adjustment longitudinally upon the propeller shaft by suitable coupling rods passing into the interior of the ship, the object of such arms or stops being to form a support for the wings to bear against when opened or expanded. The object of having two of such stops or arms placed one in front and the other in the rear of each propeller is to enable the propellers to act in either direction, and so propel the ship either "ahead" or "astern," as required. For this purpose it is only necessary to bring one or the other of the arms close against the wings, and to move the opposite one away therefrom, so as to allow the wings to expand either at the forward stroke (when the stops or arms are in a position close up behind them) or to expand at the back stroke, when the opposite stops or arms are brought close up to the wings. The two propellers are moved to and fro alternately, so that a constant propelling action is maintained. *Patent completed.*

401. W. F. SMITH and A. COVENTRY. *Improvements in, and applicable to, lathes for turning and cutting screws.* Dated Feb. 14, 1862.

This consists in employing three or more dies or cutters, but the inventors prefer to use three arranged round the article to be cut at a distance of 120° apart; these dies are cut in a similar manner to those for ordinary screw cutting with stocks and dies, and are carried by a stand, which is fixed to the slide carriage of the ordinary screw-cutting lathe, arranged so that the slide carriage can be quickly detached from the screw giving motion to it, and traversed on the bed independently of the screw. *Patent abandoned.*

402. H. COLWELL. *An improved truss for hernia, prolapsus uteri, and prolapsus ani.* Dated Feb. 15, 1862.

Provisional protection has not been granted for this invention.

403. T. RENISON. *Improvements in water-closets.* Dated Feb. 15, 1862.

This invention is not described apart from the drawings. *Patent completed.*

404. J. H. JOHNSON. *Improvements in timekeepers.* (A communication.) Dated Feb. 15, 1862.

This relates to a peculiar construction of what the inventor terms a "galvanic chronometer with centrifugal regulator," and consists: 1, of a peculiar construction and arrangement of electro-magnetic machine for actuating the works of the chronometer, and of which it forms a part; 2, of a peculiar construction and arrangement of centrifugal regenerator for controlling the speed of the electro-magnetic machine, and so regulating the movements of the chronometer. *Patent abandoned.*

405. W. Avery. *Improvements in machinery for the manufacture of screws, a part or parts of which improvements may also be used in the manufacture of pins, rivets, and nails.* Dated Feb. 15, 1862.

This invention is not described apart from the drawings. *Patent completed.*

406. G. H. Law. *Improvements in the construction of steam and other boilers.* Dated Feb. 15, 1862.

This consists in constructing the bottoms and those portions of steam and other boilers which are the heating surface thereof, as far as practicable, in the form or manner of pyramids, or halves, quarters, thirds, or other definite portion of pyramids, or as triangular, or approximatively triangular, troughs, or as cones, conoids, or the approximation thereof, or in manner of the forms and figures the reverse of these, or in honeycomb form. *Patent abandoned.*

407. J. Wall and T. Dodd. *Improvements in the construction and arrangement of apparatus for regulating the flow or passage of fluids.* Dated Feb. 15, 1862.

This relates to an equilibrium three-way tap so planned that, by movement of the spindle, a supply of fluid is permitted to flow through in one direction, and on movement the contrary way, the supply is closed, and the same fluid returned through the same tap or apparatus, and finally passed off or discharged by a third way. This tap has a rigid spindle, on which is a button or other valve fitted to close against suitable seatings. *Patent abandoned.*

408. C. Turner and J. Shaw. *Improvements in felted fabrics.* Dated Feb. 15, 1862.

This consists in the introduction of threads or yarns of wool, or any suitable materials, betwixt the layers, sheets, or films, transversely or crosswise, of the fabric, the whole being felted or wrought together into a compact substance or body by the usual process of felting, whereby felted fabrics are very much strengthened, or rendered more adhesive in their texture. *Patent completed.*

409. T. Horsley. *Improvements in apparatus for turning and closing the cartridges of breech-loading fire-arms.* Dated Feb. 15, 1862.

The cases of these cartridges consist of cylinders of pasteboard closed at one end with a metal disc; the charges of powder and shot, separated by a wad, are introduced into this case, which is then closed at the end by means of another wad, which is held in its place by turning over it the edges of the pasteboard cylinder. The present invention consists in apparatus for pressing down the wads into their places, and for securing the upper one. *Patent abandoned.*

410. J. Cooke. *Improvements in marine propulsion.* Dated Feb. 15, 1862.

This consists in certain improved methods of arranging screw and other propellers, whereby a high rate of speed may be attained with a comparatively small expenditure of power, such results being effected by pressing or forcing the water to the sides of the ship or vessel to be propelled. For these purposes the patentee uses either screw propellers of any of the known kinds, or any other propellers which may be adapted for the purposes of the invention, which does not consist in the form, but in the arrangement and disposition of the propellers with regard to the hull of the vessel. In order that the water may be pressed or forced into the "rim" of the ship or vessel, meaning thereby all that part of the vessel which tapers towards the stern, he places the screws or other propellers at certain convenient distances from each other in the rear of the mid-ship section, the same being arranged at such angles as to effect the purpose before-named, and being supported, when necessary, by bearings on the exterior of the hull. The screws or propellers are thus placed on each side of the hull opposite or nearly opposite to each other, and are driven by a shaft extending along the ship or vessel in the ordinary way, and actuating the whole system of screws or propellers by means of suitable gearing. *Patent completed.*

411. D. D. Kyle. *An improved method of communicating or signalling in and with railway trains.* Dated Feb. 15, 1862.

This consists in the production and maintenance of a continuous sound or alarum in any part or parts of a railway train, and in effecting the communication or signal by the interruption or stoppage of this constant sound or alarum. This is effected by forcing air or steam through a tube or tubes, which acts upon whistles or other suitable apparatus. *Patent abandoned.*

412. R. Bunting. *Improvements in the manufacture of bolsters and scales, and in machinery employed therein.* Dated Feb. 15, 1862.

This consists in cutting ornamental bolsters and scales of various designs in horn, bone, ivory, wood, pearl, tortoise-shell, gutta percha, india rubber, and all other materials adapted to the making of hafts or handles for cutlery, and especially for spring cutlery, table knives, bowie knives, and lock knives. The machinery consists of a table or bed, upon which are fixed bearings for supporting a shaft carrying fast and loose pulleys; a circular saw is keyed on the shaft for the purpose of cutting up the material, also a wheel or roller having the pattern cut on the face thereof, which it is desired to produce on the bolster or scale. The pattern roller is made to revolve, and the bolster or scale being held on a rest against it, the pattern is cut thereon. *Patent completed.*

413. J. Chatterton and W. Smith. *Improvements in telegraph cables.* Dated Feb. 15, 1862.

The inventors claim: 1, coating or covering the wires or strands of wires which are to be used for the external protection of the insulated conductor or conductors in telegraph cables with lead or other soft metal or alloy, whether such wires be previously tinned or coated with an adhesive compound or not. 2, coating or covering strands of wires, each strand composed by preference of three wires, to be used for the external protection of the insulated conductor or conductors of telegraph cables with an adhesive compound and gutta percha. 3, coating or covering such strands of wires as aforesaid with a mixture of marine glue or other suitable adhesive compound and fibrous material. 4, coating or covering such strands of wires as aforesaid with marine glue or other suitable compound mixed with fibrous material or not, and with one or more coatings of tape or other like suitable fibrous material. *Patent completed.*

414. R. Bell. *Improvements in treating fabrics or articles composed of animal and vegetable substances for the purpose of separating one class from another.* Dated Feb. 15, 1862.

This consists in subjecting fabrics or articles composed of animal and vegetable substances to the action of muriate or hypochlorate of manganese, and afterwards to the action of urine or chloride of sodium, and to the process of washing in rain water, or in water containing an alkali, by which means the vegetable substances are dissolved or washed away, and the animal substances are separated and retained for use. *Patent abandoned.*

415. A. H. Harrison. *An improved under-garment for gentlemen and ladies' wear.* Dated Feb. 15, 1862.

This consists of an under-garment, in which are combined in one article the two garments known as the under-vest or "jersey" and the "drawers." The patentee makes the garment open down the front, and also behind upwards from the fork of the drawers as far as the waist, and he fastens the same by buttons or other fastenings. He makes the sleeves and legs (by preference) of half length, and the garment may be composed of cotton, linen, silk, woollen, or other material. *Patent completed.*

416. J. Green. *Improvements in the method of, and apparatus for, signalling, which improvements apply to signals used with steam ploughs or cultivators.* Dated Feb. 15, 1862.

This consists in the use of a cord or rope formed of wire or other material, through which signals from the ploughman or anchorman can be made to the engineer. In order to effect this the inventor attaches one extremity of the cord or wire to a pulley or drum, which is fixed on the framework of the engine or windlass in any suitable way. The other extremity of the wire is attached to the anchor and plough, and, consequently, will be extended from one side of the field to the other. By this means the ploughman and anchorman can signal to the man in charge of the engine or windlass. The wire or cord is kept at the required tension by two cog-wheels of suitable diameter, with corresponding pulleys or drums acted on by a weight. This last apparatus is fixed on the engine or windlass, and is connected with a whistle or bell for attracting the attention of the man at the engine or windlass. *Patent abandoned.*

417. J. Russell. *Improvements in the method of raising sunken, submerged, or stranded vessels.* Dated Feb. 15, 1862.

The patentee claims the introduction into the interior and between the beams of the vessel of floats, pontoons, caissons, air barrels, or such like apparatus, and also bags or floats of a flexible nature, as described, and the introduction of air into the inside of these floats, &c., thereby displacing the water out of the hold and between decks of the ships operated upon. *Patent completed.*

418. F. W. Gerish. *Improvements in pumps.* Dated Feb. 17, 1862.

Here, in order to obtain a reciprocating right-line motion to the pump rod, a fixed toothed wheel is employed, and the shaft which gives motion to the pump rod passes through and rotates within the centre of the fixed cog wheel. On this shaft is a crank, on the crank pin of which is mounted a pinion, the teeth of which gear into the teeth of the fixed cog wheel. To the pinion the end of the pump rod is attached at a distance from its centre, corresponding with the radius of the crank; hence, by the rotation of the shaft, the crank will carry the pinion round with it; and as the teeth of the pinion at all times gear with the teeth of the fixed wheel, the pinion is caused to rotate on the crank pin, so that, supposing the pump barrel to be vertical, the pump rod will at all times be vertical, and will, when at its highest point, cross the centre of the fixed wheel, which, by preference, is formed with internal teeth. The barrel of a pump may, when desired, be in a horizontal or other position. *Patent abandoned.*

419. H. J. and R. Crawford, with R. Templeton. *Improvements in looms for weaving.* Dated Feb. 17, 1862.

The patentees claim, 1, the arrangement, construction, and combination of parts forming the self-acting movement or mechanism for actuating the rotatory shuttle boxes of looms for weaving, so that, when the weft in the shuttle becomes expended or broken, the shuttle-box is shifted round, and a new shuttle is brought into operation, as described. 2, the arrangement and construction of shuttles with spring spindles and lateral springs; also the forming of pirns with end recesses to be used with such shuttles, so that, when the weft is exhausted, or nearly so, the lateral spring is liberated, which brings into action the movement by which the shuttle-box is shifted round a cell, as described. 3, the system or mode of causing the rotatory shuttle-boxes of looms to be moved round to the extent of one cell, upon the weft breaking or becoming exhausted, which is accomplished by mechanical movement or combination of parts connected with the weft-fork or protector, as described. 4, the system or mode of letting back the "take-up motion" one or more teeth of the ratchet wheel while the loom is weaving, which is done by the arrangement and combination of parts described. 5, the system or mode of weaving checked, striped, figured, and other similar fabrics, by the mechanical arrangement or combination of parts for bringing the cells of the shuttle-box round in the required succession, as described. *Patent completed.*

420. J. Hodgkinson and D. Greenhalgh. *Improvements in machinery or apparatus for preparing or combing cotton, wool, and other fibrous materials.* Dated Feb. 17, 1862.

This consists, 1, in the use of one or more stationary knives in conjunction with a brush for pressing the fibrous materials into the comb. 2, in the use of an endless travelling apron for the purpose of removing the waste from the comb. The apron is composed of wire or bristles, set in canvas or other suitable material, or upon metal lugs, hinged together and working over the ordinarily chain wheels, and is kept clean by a revolving or oscillating stripper. *Patent completed.*

421. J. Whitaker. *Improvements in machinery or apparatus for pulping roots.* Dated Feb. 17, 1862.

Here the inventor employs a number of shafts mounted with cutters in a spiral direction, and gives to each shaft and cutters a compound revolving motion. All the shafts are placed upon a revolving frame, and each shaft turns on its own axis in a similar way to the well-known "sun and planet" motion, by means of toothed pinions gearing into a stationary spur wheel. The roots are placed in a box or case, and are pulped by coming in contact with the aforesaid compound revolving action of the cutters. *Patent abandoned.*

422. J. J. Van den Berg. *An economical fire-kindler.* Dated Feb. 17, 1862.

This fire kindler is composed of chips of cork and resin. *Patent abandoned.*

423. E. T. Hughes. *An improved method of, and apparatus for, collecting the gases given off from furnaces.* (A communication.) Dated Feb. 17, 1862.

This invention is carried out in the following manner: At the top of the furnace, and surrounding its opening, there is a metal casing having apertures for allowing the furnace to be fed, and also formed at the top so as to support the gas pipe or chimney, the bottom of which is at such a distance from the top of the furnace as to offer no obstruction to the feeding of the material. At the edge of the opening of the furnace, and at the bottom of the chimney, there are conical rings which support a cap or cover when the space is required to be closed. The cap or cover has a balance-weight for raising or lowering it with facility. When raised, the furnace can be fed, but when lowered, the space is effectually closed by the cover which collects the gases, and allows them to escape only through the gas pipe or chimney. At the top of the gas pipe there is a safety-valve, which opens when there is excess of pressure, but which is much higher than when the operatives are engaged. *Patent completed.*

424. T. and J. Birdsall. *Improvements in preparing hides or skins for tanning.* Dated Feb. 17, 1862.

Here the patentees employ a solution of hydrochloric acid, diluted to about one thousand and ten specific gravity, in which the hides or skins are submerged, which, in a short time, kills the lime, and opens the pores of the hides or skins, the residuum being afterwards worked out or extracted by the usual means. *Patent completed.*

425. J. Combe. *Improvements in machinery for winding cops, and in the treatment of cops, for warps and other purposes.* Dated Feb. 17, 1862.

This invention is not described apart from the drawings. *Patent completed.*

426. H. E. Quant, G. H. Fisk, and W. Davies. *Improvements in securing the ends of steel or other materials used for crinolines.* Dated Feb. 18, 1862.

Here the inventors use a skeleton metal receiver into which the ends of the steel or other material are inserted, and they are held or retained in this receiver by being pressed against a chequered or roughened surface or surfaces formed in the receiver, similar to the surface of an ordinary culinary grater, the necessary pressure being obtained in some cases by a curved flat spring of a similar length and breadth to the inside of the receiver, and which is inserted (upon the steel) through or under collars or clips left or formed upon the ends of the receiver. *Patent abandoned.*

427. J. H. Hastings, J. Freezer, and J. Woods, Jun. *Improvements in ploughs.* Dated Feb. 18, 1862.

This relates to the double furrow plough to be worked by two or more horses, according to the depth of the work to be done, and so constructed as to be capable of being set to any width or depth of work desired, and also of being adapted as a subsoiler when required for that purpose. The handle of the plough is similar in form and construction to that ordinarily used, and the beam is carried by standards or loads similar to those now in use. The frame is made of wrought iron, the side pieces being connected together by screwed rods, so as to be capable of being set to the desired width. A complete plough is attached to each side of the frame, one being in advance of the other. For ploughing turnip grounds or other similar purposes two cast breasts or plats are used to turn the mould over, and for ploughing wheat stubblers, instead of the two cast breasts, two wooden boards are used to leave the mould open to the atmosphere as much as possible without turning it over. For subsoiling the ground, the foremost plough is removed from the frame, and a subsoil-head is fixed on in its stead, which subsoil-head, being provided with one or two points or cutting shares, enter the ground. *Patent abandoned.*

428. R. Watkins. *Improvements in producing light in oil and spirit lamps, parts of which improvements are applicable to lamps generally.* Dated Feb. 18, 1862.

This relates in part to lamps of all kinds, and in part, and more particularly, to that class of lamps in which the light is produced from the gas or vapour evolved, generated, or raised from and by the application of caloric or heat to volatile oils, spirits, compounds, or liquids, suitable for the purpose, and consists in improvements in the form and construction and mode of fitting the burners movable, and other parts of lamps, and in admixing and compounding in the various specific proportions the oils, spirits, or liquids to be used therein. *Patent completed.*

429. C. D. Segoffin. *An improved apparatus for looking at photographic cards—"microphore."* Dated Feb. 18, 1862.

This consists in the construction of an apparatus of a rectangular form, three sides of which are closed, the fourth being partly open for the admission of light on to the card placed at the back, the smaller side opposite having a magnifying glass which allows of a good view of all the details of the photographic card. For viewing proofs that are placed in albums the inventor makes the apparatus without a back, so that all that is required to be done is to place the apparatus over the proofs to see them distinctly. The sides of these instruments are formed with stiff or flexible materials, and of a bellows form, that is to say, with parts folding on themselves. To these small apparatus he has given the name of "microphore." *Patent abandoned.*

430. J. Lees. *An improved trap for catching rats, mice birds, and other animals alive.* Dated Feb 18, 1862.

This consists of a box or case formed with open ends and top, or, in other words, a box formed with a solid bottom and sides lined with sheet metal; the top (if the trap be for catching small animals such as rats, mice, birds, &c.) may be formed of wire, or wire and sheet glass; one end also may be of strong glass; at the other end is a door or flap hinged to the upper part of the trap, the said door or flap having a spring bolt affixed to the outside thereof, so as to project beyond the bottom edge of said door or flap, the point of the said bolt taking into a hole in the bottom of the box or case. Within the said box or case, and at a short distance from the glass end thereof, a wire frame covered or laced with twine is suspended from the top of the trap; the top of said wire frame has a hook affixed thereto, which projects above the top of the trap, the said hook being used to keep the door of the trap up, when set for use, by a spring rod fixed to the said door, the other end of the rod being lightly adjusted and held by the aforesaid hook. *Patent abandoned.*

431. W. Clark. *Improvements in gas apparatus used for lighting cigars and other tobacco.* (A communication.) Dated Feb. 18, 1862.

This consists of a hollow metal tube fixed to a handle by means of a socket. The lower end of the first tube carries a tube of smaller diameter, serving for the filtration, and for the burner of the gas. The upper end of the hollow metal tube has a screw thread for the purpose of fixing a metal stopper therein, which is slightly fitted so as to allow of a small jet of gas escaping between the tube and the stopper. This stopper has an opening at its centre carrying a rod, having a valve at its lower part, and a hook at the upper part. This valve is

formed of several round balls forming a weight, which opens and closes hermetically the opening in the stopper. The hook at the upper part of the rod is attached to a cord of less length than that of an india rubber tube, which encloses the whole, and serves to conduct the gas. *Patent abandoned.*

432. M. HENRY. *Improvements in cartridges.* (A communication.) Dated Feb. 18, 1862.

Here the inventor employs a tube or case of metal, or other impervious material or substance not porous to damp, wet, or air. He preferably forms this case tubular or cylindrical, or as a short tube, and closes one or both ends by a plug or stopper of cork, india rubber, or gutta percha, and to one or both of which he sometimes fixes a disc or plate of larger diameter. He prefers also placing a collar round the tube to prevent its slipping too far down the barrel of the arm. He manufactures an improved ball cartridge thus: he inserts the ball into such tube, pushes it part of the way down therein, introduces the powder, and closes the tube with the stopper. He packs the groove of grooved projectiles with hemp, or the like soaked in or covered with tallow, &c. *Patent abandoned.*

433. W. BUSH. *Improvements in omnibuses and other carriages.* Dated Feb. 18, 1862.

This invention consists in constructing omnibuses and other carriages with parts thereof double, so that the bottom sides and top may, when required, be drawn out and afford increased accommodation. An ordinary omnibus, for instance, is built to hold twelve persons inside; by this invention the inventor proposes, that when required it shall contain twenty persons inside. The fore part of the carriage is immovable, but all that part commencing just in front of the hind wheels, together with the hind wheels and axle, are capable of being drawn say six feet from the fixed part, the space being occupied by duplicate parts, over which the parts of the carriage drawn out have been made to slide. The invention applies also to vans and other long-bodied carriages. The invention also consists in constructing the frames for omnibuses, trucks, and other carriages of angle iron, and in screwing, bolting, or riveting to the angle iron, for forming parts of the framing, two other angle irons, with timber fixed between the two last-named angle irons, to which timber the panels and other required parts to complete the carriage are screwed or otherwise secured. Thus the whole of the framing and skeleton of the carriage are formed of angle iron and of two angle irons with timber between them. The invention further consists in constructing trucks and carriages in such manner that they may be used on rail or tramways and in common roads. For this purpose the inventor fits a plate or plates under the fore part of the truck or carriage, free to turn upon a pivot, and connects the front axle and wheels to this plate. If travelling upon a rail or tramway, he bolts the plate so as to prevent its moving, but when the carriage is to run upon ordinary roads, he releases the bolts, when the plate and "fore carriage" are free to move about the pivot, and thus allow of the carriage turning. The wheels are such as will travel upon rails or trams as well as upon common roads. *Patent abandoned.*

434. W. FIRTH. *Improvements in machinery for digging or turning up soil.* Dated Feb. 18, 1862.

This invention is not described apart from the drawings. *Patent completed.*

435. C. T. MARZETTI and J. WATSON. *Machinery or apparatus for raising, lowering, and otherwise moving or disposing casks and other heavy bodies.* Dated Feb. 19, 1862.

This consists in using a tangent wheel and screw, or worm and worm-wheel movement, in combination with a winding barrel or shaft, upon which is wound the chain or rope, to the one end of which the cask or other body, or the object to be raised, is attached by a sling and hook or other means, whereby a considerable economy both of labour and space is effected. *Patent completed.*

436. J. T. PENDLEBURY and G. PENDLEBURY. *Improvements in machinery for doubling, folding, or plaiting cloth.* Dated Feb. 19, 1862.

These improvements consist, under one modification, in placing on each end of a sliding table one or more pairs of jaws, each jaw being attached at one end to a lever having its fulcrum between the points of attachment, the said lever being movable about the said fulcrum; each pair of jaws is connected together by a cross bar hung upon studs or centres, the upper jaw being longer than the lower jaw. A tappet is fixed on the said lever, or on a shaft forming the said fulcrum, and is acted upon by another tappet actuated by a spring for the purpose of keeping the said jaw or jaws open or shut as required, another tappet being situate on the said shaft for the purpose of opening or closing the said jaws as needed. Above the sliding table is placed a shaft having a longitudinal aperture, the sides of the said aperture being for the purpose of holding the cloth in the right position for the jaws to take hold of it. At the ends of the said aperture a wheel is attached, the said wheel being moved by a rack actuated by some part of the machine. On the ordinary doubling table a lever carrying a roller or rollers is so placed that when the lever moves upon its fulcrum, the said roller or rollers are elevated or depressed. The last-named roller or rollers come in contact with another roller, whose circumference projects a little above the surface of the said doubling table. At the other end of the doubling table to that where the sliding table is situated, a fixed or revolving disc, or a projecting arm, acts upon the cloth in the middle of its width, and doubles the same, the said cloth being then passed through or between the before-named rollers, and through the before-named longitudinal aperture, and over the edge of one of the said sides forming the aperture, is secured by the jaws, and drawn along until the sliding table arrives near the end of its stroke, when the rack and wheel before-named being acted upon by a projecting stud or other part of the machine, cause the shaft containing the aperture to so move that the cloth which is doubled or folded over one of the sides before-named shall be so situate that the said jaw or jaws, which are now open, being acted upon by a catch, and one of the before-named tappets, shall shut or close and secure the cloth at or near the end of the stroke of the said sliding table; the said sliding table will now return and carry the cloth along with it, and another part of the said cloth being folded over the other side forming the aperture before-named, will, by a similar motion to that before-named, be brought in a position for the jaws at the other end of the sliding table to secure it, and when the jaws open the cloth is brought down on the table in any convenient way. The edges of the said sides are notched to enable the jaws to secure the cloth. *Patent completed.*

437. H. B. BARLOW. *Improvements in carding or otherwise preparing cotton and other fibrous materials and in machinery employed therein.* (A communication.) Dated Feb. 19, 1862.

The object of this invention is to dispense with the use of the carding engines now employed; and it is particularly suitable for preparing cotton or other fibrous materials for the combing machines. In performing this invention, a lap is prepared by a blower and lap machine of the usual construction, or in any convenient way, and the lap so formed is placed at the back of the machine, and the fleece of fibrous materials passes between fluted rollers to a roller covered with card teeth working in a trough. This roller delivers the fibres to a large drum, also covered with card teeth, the fibres are forced between the teeth of the large drum by a current of air passing under the trough above referred to; the card fillet of the large drum is put on in annular rings, or in spirals, with a space between them, and the fibres are collected by the teeth of the cards until a certain thickness has accumulated; the large drum is then turned round in the reverse direction and the narrow fleece or fleeces of fibres are drawn off by a pair of fluted rollers or otherwise; these fleeces are then passed through drawing rollers, and are then ready for the combing machine. *Patent abandoned.*

438. J. NASMYTH. *Improvements in the method of obtaining motive-power, and of applying it.* Dated Feb. 19, 1862.

This consists in placing in the centre of a stationary cylinder a socket, in which turns a rod or shaft, passing through the cover of the cylinder at a suitable distance from the centre of the cylinder. The patentee places in it a movable solid circular substance, or a movable tube with an arm or arms fixed in the shaft, which shaft passes through the cover of the cylinder. The movable solid circular substance, or the movable tube with its arm or arms, circulates steam-tight between the top and bottom of the cylinder and the said movable solid substance, or the said movable tube. He places a plate of any appropriate material, which plate he calls a piston, and fixes it to the said solid circular substance, or the said movable tube. He then introduces steam or any elastic or non-elastic substance on the surface of the plate or so-called piston, by which the movable solid circular substance, or a movable tube with its arm or arms, moves inside the cylinder through a door attached by hinges or other means to the cylinder, which door is opened by the piston as it passes and is shut and kept shut by a spring fixed in a recess of the cylinder, or by the pressure of steam. *Patent completed.*

439. F. BARNETT. *An improved lamp or lantern for street lighting and other purposes.* Dated Feb. 19, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

440. W. B. ADAMS. *Improvements in springs and their arrangement for moving and stationary purposes.* Dated Feb. 19, 1862.

This invention is not described apart from the drawings. *Patent completed.*

441. N. SYMONS. *Improving the power of steam-engines by a different form of piston, internal top and bottom of cylinders, also for increased strength and lightness for all kinds of wheels, framework girders, blades of blowing fans, and paddle wheels.* Dated Feb. 19, 1862.

This refers to a mode of increasing the surface and motive power of pistons, internal top and bottom of cylinders, by means of corrugations, indentations, or grooves, or in any other form or shape that will increase the superficial area without increasing the diameter of cylinders. *Patent completed.*

442. J. TURNER. *Improved machinery for mixing, mincing, and pounding.* Dated Feb. 19, 1862.

This consists in constructing machinery so that motion is imparted to a cross-head by side levers and two sets of cogged or toothed wheels. Two of these are keyed on to a horizontal shaft, supported by a frame, the other wheels being connected with the levers. A mixing receiver, surrounded by a toothed band, and supported by a frame capable of being tilted, is situated beneath the cross-head, and is made to revolve on a centre point by a screw in the shaft. The whole may be fixed to a bench or dresser by a clamp or other means. The utensils may be attached to the cross-head aforesaid, and be either fixed or free. *Patent abandoned.*

443. W. HINTON. *Improvements in barometers.* Dated Feb. 19, 1862.

Here the patentee makes the dials or indicators of any description of barometer, especially of wheel barometers, either of glass ground, or of glass having paper, linen, calico, silk, or other similar substance attached thereto, with the various indications marked, printed, or transferred thereon; thus the dials would have a semitransparent appearance, and when placed in suitably-constructed framings facing the sea, could be observed from a distance. At night a light or illumination is to be placed behind the said dials, which being semi-transparent, will allow of their being raised to higher situations than usual, and thus permit of the various indications being seen with facility and accuracy, even from a great distance. *Patent completed.*

444. W. DAVIS. *Improvements in increasing the illuminating effect of coal gas, and other gases.* Dated Feb. 19, 1862.

The patentee claims: 1, increasing the illuminating power of coal gas and other gases by hydro-carbons, or carburetting materials, or enriching, or auxiliary agents, conveyed continuously from their receiver or holder, while the combustion of the gas under treatment is going on, to a receiver, holder, or part in such proximity to the burner at which the gas is undergoing combustion, that the heat produced by such combustion shall evolve vapours from the hydro-carbon or carburetting material, or enriching or auxiliary agent, which vapours shall combine with the gas under treatment, and thereby increase its illuminating effect. 2, the mode of increasing the illuminating effect of gas by hydro carbons or carburetting materials, or enriching, or auxiliary agents, contained in a holder below the burner, from which holder they are gradually raised to the neighbourhood of the burner by capillary action or other means, so that the heat transmitted from the burning gas shall evolve vapours from them which combine with the gas and increase its illuminating effect. 3, the mode of applying threads of cotton or other fibrous material for re-using the hydro-carbon or carburetting material, or enriching, or auxiliary agent, according to which the threads carried from the holder of the said hydro-carbons or agents are coiled or wound in the neighbourhood of the burner for the purposes set forth. 4, the mode in which the hydro-carbon or carburetting material, or enriching agent, is raised to the centre of the burner below the part where combustion is going on, so that it may give off vapours which combine with the burning gas, substantially as described. *Patent completed.*

445. J. PATERSON. *Improvements in means or apparatus for reburning animal charcoals.* (A communication.) Dated Feb. 19, 1862.

For this purpose the retorts, which are of a cylindrical form, may either revolve continuously in one direction, or partly in one direction and then in the other, and instead of being placed with their axes in a horizontal direction, they are inclined, and they receive the charcoal to be reburned at their higher ends through suitable channels, and then by the revolution of such retorts the contained matter will progressively traverse to the lower ends thereof, where there are vanes or cups, or other suitable means adapted to take up such matter and discharge it into a receiver projecting inwards from such lower ends, and having a communication with the cooling apparatus. Series of such retorts are also arranged to work together, each being caused to revolve, and being inclined from the feeding to the delivery end, as stated, with the delivery end of the first discharging by a suitable way into the feeding end of the next, and so on with the succeeding retorts of the series. The feed and discharge pipes are connected to the respective ends of the retorts in manner to admit of the retorts revolving. The charcoal from each retort, or from the last of a series of them, is conducted into suitable coolers before exposure to the atmosphere, and a jet or jets of water are used to operate upon the external surfaces of the cooling chamber, or the passage or passages to them to facilitate the cooling process. The lifting means at the ends of the retorts may be separate and operated by mechanical means. The patentee arranges the retorts when in connected series, so that the last of the series is that to receive the most heat, and the next less, and so on to the first, which receives the last. The gas or vapour generated during the process is allowed to flow back and escape by the feed-pipe, so as to avoid remixture with the manufactured or reburned charcoal. *Patent completed.*

446. J. GREGORY. *Improvements in candlesticks.* Dated Feb. 19, 1862.

Here, in order to hold candles of different sizes at different times securely in the nozzle and socket of a candlestick, and yet not interfere with the candle being raised therein, a grip or holder is applied within a suitable chamber or recess in the nozzle or upper part of the candlestick. It is preferred that this grip should be formed in two parts or lever jaws, with a space between them suitable to receive the smallest size of candle when the lever jaws are closed. These lever jaws are capable of being separated more and more, according as it is required that a larger candle should be placed between them. The lever jaws are pressed towards each other by a spring or springs, so that a candle when held between is pressed on both sides by the two lever jaws. Each of the two jaws turns on its own centre or axis. One end of one of the jaws passes out to the exterior of the nozzle of the candlestick, so as to admit of its being moved a distance by the finger when the two jaws are to be separated to admit of a candle being introduced between them into the socket; and the lever jaws are so combined that, by pressing the part of the one which protrudes, the other is also moved away, so as to enlarge the space or opening between the two jaws. *Patent abandoned.*

447. G. T. BOUSFIELD. *Improved modes of protecting iron boilers, tanks, and vats from wear arising from galvanic action.* (A communication.) Dated Feb. 19, 1862.

This consists, 1, in interrupting the galvanic action which is produced in iron boilers, tanks, vats, &c., by their connection with pipes, pumps, condensers, faucets, or other fixtures of brass, copper, or other metals electro negative to iron, by the use of insulating joints, by which the two metals are separated by a packing of india rubber or other con-conducting substance. 2, in arresting and depositing from the water, before it is admitted to the boiler tank or vat, the copper or other metallic salts held in solution by it, which it has taken up in its contact with the copper or brass fixtures through which it has passed, by first passing the water through a vessel containing zinc in small pieces, or its equivalent in galvanic properties, on which the copper or other metal negative to iron will be deposited, and not be carried into the boiler or tank to produce there a galvanic action, so destructive to the iron vessel. *Patent completed.*

448. J. WILCOX. *Improvements in the manufacture of frills or ruffles, and in the machinery or apparatus employed therein.* (A communication.) Dated Feb. 19, 1862.

The essential peculiarity of these frills, ruffles, or trimmings, is that the folds or plaits are crimped in one direction, and transversely to the cloth in a perfectly even and regular manner, and secured by stitches, in lieu of the fabric being puckered or gathered in the ordinary way. Another peculiarity is, that the hem or hems, or selvages, on one or both edges of the fabric, are crimped simultaneously with the intermediate portion. *Patent completed.*

449. G. P. LEE. *An improvement in tourniquets.* (A communication.) Dated Feb. 20, 1862.

This consists in the use of an arterial or compression pad, connected by a non-elastic band with an adjustable counter-acting pad, so that the flow of blood in any particular artery may be stopped without interrupting the flow of blood in the veins. The required pressure is applied and regulated by an elastic band attached to the end of the former (non-elastic) one, wound round upon, and itself securely fastened. *Patent completed.*

450. J. FRIEDLAENDER. *Improvements in machinery for scutching, breaking, and preparing flax, hemp, jute, and other fibrous materials.* Dated Feb. 20, 1862.

In a suitable framing, the patentee mounts a revolving shaft, on which is fixed a series of sets of lifting arms, which operate on tappet pieces fixed one on each of a series of vertical rods, mounted and working in guides fixed to the framing of the machinery, there being as many separate sets of lifting arms aforesaid as there are separate rods and tappets; the lower end of each of the aforesaid rods has a piece of wood or beater affixed thereto, and another piece of wood of the entire length of the series of beaters is also fixed to the bottom of the machinery; the bottom edges of the aforesaid beaters are formed rounded, and there are corresponding grooves made in the aforesaid solid piece of wood. One portion of the operations of this machinery is as follows:— The beaters being raised, the flax or other fibrous material is placed upon the grooved piece of wood aforesaid; the machinery being then set in motion, the lifting arms, as they rotate, release the beaters, and allow them to fall on the flax or fibrous material beneath, thereby breaking the straw and softening the same in a speedy and efficient manner without breaking the fibre. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated April 17, 1862.

1132. S. Rideal, railway carriage builder and engineer, Manchester, and R. Shepherd, gentleman, Great Grimsby, Lincolnshire. Improvements in railway break apparatus.

Dated July 15, 1862.

2029. A. Couvreux, 333 Rue Saint Martin, Paris, contractor. An improved centrifugal apparatus for breaking stones.

2031. A. Couvreux, 333 Rue Saint Martin, Paris, contractor. An improved centrifugal apparatus for casting stones and other materials, and in forming embankments and other structures.

Dated July 21, 1862.

2069. J. W. Green, 2 St. Paul's Buildings, Little Carter Lane. An improved method of cutting sheet and plate glass to any given design, giving the finished form the brightest polish possible. (A communication.)

Dated July 24, 1862.

2109. M. Henry, 84 Fleet Street. Improvements in apparatus for retarding and stopping carriages, especially applicable to railway carriages, and in disconnecting apparatus for carriages. (A communication.)

Dated August 2, 1862.

2191. E. B. Wilson, Parliament Street, Westminster, engineer, and M. Picard, Lyons, engineer. Improvements in the manufacture of iron and steel.

Dated August 5, 1862.

2200. M. J. Roberts, Esq., Pendarren House, near Crickhowell, Brecon. Improvements in means or apparatus for spinning and preparing wool and other fibrous substances.

Dated August 7, 1862.

2209. M. A. F. Mennons, 24 Rue du Mont Thabor, Paris. An improved self-inking hand stamp. (A communication.)

2213. J. H. Johnson, 47 Lincoln's Inn Fields, gentleman. Improvements in blast furnaces. (A communication.)

2217. B. Coombe, 30 Mark Lane, manufacturer. Improvements in apparatus or machinery for cleaning and decorticating wheat and other grain.

Dated August 8, 1862.

2219. E. Hall, Butts Green, Luddenden Foot, near Halifax, corn miller. Improvements in means or apparatus for preparing foreign grain for grinding.

2221. F. M. Jennings, Cork, merchant. A composition for coating ships' bottoms to prevent fouling.

2223. N. J. Amies, Manchester, manufacturer. Certain improvements in the manufacture of bearings, "journals," and "steps," employed in machinery, and for carriage and other axles.

2227. J. Tatham, Rochdale, machine maker. Improvements in machinery or apparatus for preparing, spinning, and weaving cotton and other fibrous materials, parts of which improvements are also applicable to other mechanism, in which an uniform or variable rotatory motion is required.

Dated August 9, 1862.

2228. J. Mackintosh, North Bank, Regent's Park. Improvements in obtaining and applying motive power.

2229. R. Fowler, Glasgow, timber merchant. An improved manufacture of woven, plaited, knitted, and other fabrics.

2231. Sir J. S. Lillie, Knight and Companion of the Most Honourable Military Order of the Bath, 105 Pall Mall. Improvements in carriage ways and footways.

2233. A. J. Moreau, chymist, and A. E. Ragon, gentleman, Bernard Street, Russell Square. Improvements in the mode of and apparatus for treating bituminous and carbonaceous substances for the purpose of obtaining the various products, volatile, liquid, and solid, which they contain, and also in the treatment and application of such products.

2235. T. De la Rue, 84 Westbourne Terrace. Improvements in the manufacture of pigments and writing inks.

Dated August 11, 1862.

2237. H. B. Barlow, Manchester. Improvements in machines for weaving, warping, sizing, and dressing. (A communication.)

2239. W. E. Newton, 66 Chancery Lane, civil engineer. Improved machinery for compressing powder for cartridges. (A communication.)

2241. T. Holdsworth, Shaw Lodge Mills, Halifax, manufacturer, and J. Crossley, Bank Bottom Mills, Halifax, machine maker. Improvements in means, machinery, or apparatus for warping, scouring, sizing, stretching, measuring, cooling, drying, and beaming yarns for weaving.

2243. N. J. Amies, Manchester, manufacturer. Improvements in the manufacture of bearings or steps employed in machinery and railway and other carriages, and in a composition to be applied thereto.

2245. M. H. Champion, 15 Passage des Petites Ecuries, Paris. Self-closing buttons fastening without thread or needles.

2247. J. Combe, engineer, and J. H. Smalpage, woollen draper and tailor, Leeds. Improvements in the action and arrangement of machines for winding cops, and in apparatus for holding and receiving such cops when used for warps or sewing thread or other purposes.

2249. A. J. Martin, High Street, Bow, J. Goss, Prospect House, Bow Road, and J. Bush, Bow Common, Bromley. Improvements in apparatus for distillation.

Dated August 12, 1862.

2251. W. Macnab, Greenock, engineer. Improvements in steam boilers and in apparatus for feeding the same, and for effecting circulation therein.

2253. J. Dickson, 66 Tollington Road, Holloway, gentleman. Improvements in treating zinc ores and solutions of zinc to obtain zinc therefrom.

2255. L. Serbat, Valenciennes, France, gentleman. Certain improvements in lubricating machinery.

2256. C. A. Wheeler, Swindon, Wilts. Improvements in machinery for perforating paper.

2257. A. Delrue, Dunkirk. Improvements in compositions for preventing and removing incrustation in boilers.

2259. J. Langran, Kimbolton, Huntingdonshire, millwright. Improvements in apparatus for driving agricultural machinery.

2261. A. B. Childs, 481 Oxford Street, engineer. Improvements in machinery for cutting veneers. (A communication.)

2263. G. Sanders, Nelson Place, Old Kent Road, gentleman. Improvements in domestic fire-escapes.

Dated August 13, 1862.

2265. J. Dickson, 66 Tollington Road, Holloway, gentleman. Improvements in the manufacture of chlorine for commercial purposes.

2267. J. Cooper, Town Malling, plumber. Improvements in valves and buckets for pumps, and in valves or cocks for other uses.

2268. J. Smith, Regent Street, Mile End Road, engineer, and J. S. Rayment, Rayment Road, Grove Road, Mile End, builder. Improvements in apparatus for generating steam and for regulating its flow, part of which improvements are applicable also to other purposes.

2271. W. L. Boyle, California; Eastbourne Terrace, dentist. Improvements in the construction of chairs and foot stools for the use of dentists, and in chairs, couches, and beds for invalids.

2273. H. Twelvetrees, Bromley, manufacturer. Improvements in rat and mice traps.

2275. L. D. Verstraet, chemist, and E. M. Olivier, proprietor, 29 Boulevart Saint Martin, Paris. A new process of manufacturing carbonate of soda by the application of sulphuret of sodium, and in apparatus for the same.

2277. W. Schnell, 63 Charlotte Street, Fitzroy Square. Improvements in extracting the sulphur and sulphurous acid from the oxy-sulphuret of calcium, which is contained in the residues or waste material obtained in the manufacture of soda. (A communication.)

Dated August 14, 1862.

2279. E. J. Dagnall, Point Pleasant, Wandsworth. An improved tray or receptacle adapted for wash-hand stands for holding tooth-brushes, tooth-powder, and nail-brushes.

2281. J. Irvine, Patshill, Salop, musketry instructor, and J. W. Hand, Beckbury, Salop, builder. A new or improved rifle rest.

2283. G. Welch, Birmingham, manufacturer. Improvements in inkstands, metallic pens, and penholders, and other instruments and appliances used in writing and marking.

2285. W. Beatson, Rotherham, stove grate manufacturer. Improvements in the manufacture of stoves.

2287. D. P. Marques, Barcelona. Improvements in apparatus for cleaning the bottoms of ships and vessels. (A communication.)

2289. J. Petrie, Jun. Rochdale, ironmonger. Improvements in machinery or apparatus for blowing and exhausting air.

2291. J. Hopwood, Ashton-under-Lyne, mechanic. Improvements in machinery or apparatus used for collecting fibrous material and dirt from the carriage boards and roller beams of mules and other similar machines used in spinning.

2292. J. Hearn, Hatford, Berks, clerk. Improvements in apparatus or appliances for raising sick or bedridden persons in their beds, and for lifting their bed-clothes.

2293. W. Soutter, Birmingham, coppersmith. Certain apparatus for raising and planishing metals.

2295. J. S. Blockey, Hyde Park, Leeds. Improvements in the manufacture of colouring matters.

2297. C. E. Spagnoletti, Telegraph Department, Great Western Railway, Paddington. Improvements in apparatus for signalling trains on railways.

Dated August 15, 1862.

2301. T. Carvin, Landport. Improvements in screw propellers.

2303. J. Newman, Birmingham, jeweller. Improvements in machinery for the manufacture of metallic tubes.

2305. J. H. Johnson, 47 Lincoln's Inn Fields, gentleman. Improvements in electro-magnetic time-keepers. (A communication.)

Dated August 16, 1862.

2307. H. Garside, Coupland Street, Manchester, engineer and machinist. Improvements in machinery or apparatus for marking, etching, or engraving on cylindrical and other surfaces.

2309. T. Knowles and W. Robinson, Manchester, machinists. Improvements in racks for window blinds.

Dated August, 18, 1862.

2313. F. Barnett, 164 Rue de Rivoli, Paris. An improved lamp or lantern for street lighting and other purposes.

2315. J. T. Oakley, Grange Road, Bermondsey. Improvements in heating stoves employed for drying and other purposes.

2319. H. Melton, Regent Street, hatter. Improvements in the manufacture of hats and caps.

Dated August 19, 1862.

2321. V. F. Cleuet, 182 Rue d'Allemagne, Paris, engineer. An improved self-acting apparatus for supplying boilers with water, applicable also to the raising and to the measuring of liquids.

2323. S. Boucher, Warchin, near Tournai, Belgium, flax spinner. Improvements in flax spinning, which improvements are also applicable to spinning of tow and hemp.

2325. T. H. Falkiner, Dublin, engineer. Improvements in the permanent way of railways.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

2343. C. Monson, Connecticut, United States. A new and useful repeating rotary engine. *Dated August 22, 1862.*

2345. E. S. Ritchie, Massachusetts, United States. A new and useful improvement in the mariner's compass. *Dated August 22, 1862.*

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

1132. S. Rideal and R. Shepherd. Railway brake apparatus.

1151. A. P. Tronchon. Walls, palisades, and other similar constructions.

1153. E. H. C. Monckton. Preparation of metal to be used in the construction of cannon.

1163. A. Dixon. Knife and fork cleaning machines.

1165. C. C. Creeke. Drain and other pipes.

1166. T. Lea and J. Smith. Alarms or indicators.

1171. A. Warner. Construction of vessels of war, and in floating or other batteries.

1180. W. Carpenter. Printing in colours.

1183. W. Fear. Joining the saw plates of veneer and other saws constructed in segments.

1191. J. Endean. Cocks, taps, and valves.

1194. J. Bond. Projectiles attached to vessels for war purposes.

1197. G. Davies. Manufacture of matting.

1200. G. W. Belding. Harrows or cultivators. (A communication.)

1204. R. Zimara. Heating and ventilating.

1216. J. Aspinall. Apparatus for the safe conveyance from sea to land of ship's papers, documents, money, and other valuables.

1219. A. Applegath. Printing in colours.

1226. T. U. Brocklehurst. Reeling singles, trams, organzines, and sewing silks.

1228. J. G. N. Alleyne. Iron and steel.

1233. A. Boyle and T. Warwick. Manufacturing hair pins.

1252. W. Clark. Preserving animal and vegetable substances. (A communication.)

1268. G. Davies. Electric apparatus. (A communication.)

1269. G. Davies. Nails, screws, and other analogous articles in malleable cast iron. (A communication.)

1293. W. Bodden and W. Mercer. Machinery for slubbing and roving cotton and other fibrous substances.

1295. R. Walker. Malting.

1299. R. A. Brooman. Superheating steam. (A communication.)

1301. M. Paul. Windlasses and capstans.

1324. P. V. Lefebvre. Fountain pens.

1333. F. Marrel. Forming wrought-iron bars for the manufacture of armour plates.

1353. W. Clark. Buckle or fastening. (A communication.)

1368. J. Combe. Machine for spreading and drawing into slivers flax, hemp, jute, and other fibrous substances.

1528. W. Petrie. Vessels for boiling chemical products.

1883. C. Cochrane. Manufacture of aluminate of soda and potash.

2025. F. M. Parkes. Manufacture of gas.

2135. T. Cook. Manufacture of envelopes.

2230. G. Hazeltine. Carriage wheels. (A communication.)

2256. C. A. Wheeler. Machinery for perforating paper.

2343. C. Monson. Reaping rotary engine.

2345. E. S. Ritchie. Mariner's compass.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

Note.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5*s*. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

THE

MECHANICS' MAGAZINE.

LONDON, FRIDAY, SEPTEMBER 12, 1862.

ENGINEERING SUMMARY.

Our readers will remember that three or four months since we announced that the Lords of the Admiralty, at the instance of the Atlantic Telegraph Company, ordered the steam-surveying vessel, Porcupine, to be prepared for taking soundings of a portion of the bed of the Atlantic on which the Atlantic cable was laid. We also announced that experienced officers had been appointed to undertake the survey, and that no doubt some valuable information would be obtained. The Porcupine has returned, and a fragment of a side-wind report has appeared in the *Times*. This report, which will be found in another column, says: "It is believed that, with the present limited "extent of telegraphic science, there is no "means of transmitting a message rapidly "through a great length of wire. One word "is said to overtake another, and it is averred "that the force requisite to be exerted by the "batteries for sending the fluid so great a "distance, must involve injury to the wire "by the necessary intensity of the electric "spark."

This is an absurd statement, and rests, we believe, upon no better or more solid opinion than that of an officer who, notwithstanding that by lecturing and otherwise he had prejudged the case, and shown himself a partisan of the Arctic or North-Atlantic scheme, before the Admiralty had complied with the request of the original Atlantic Telegraph Company, was yet permitted to accompany the expedition. His views, however, will have little weight, as his objections have long since been contradicted by such men as Professor Wheatstone, Dr. Thomson, Mr. Varley, Mr. Fleming Jenkin, and Mr. Thomas Allan, all of whom state in the most positive terms that a line, efficiently laid between Newfoundland and Ireland, will work at a speed of from eight to sixteen words per minute. Moreover, Messrs. Glass, Elliot, & Co., the contractors, have offered to guarantee the efficient working of such a line, under heavy penalties. As to large battery power being required for long lengths of cable, this objection is equally unsupported by fact. We happen to know that the Toulon and Algiers cable, which is 600 miles in length, is most efficiently worked with a power not exceeding sixteen small cells of Daniell's battery.

We may soon expect to find the Atlantic Telegraph enterprise again the subject of enquiry and speculation. We have heard that Mr. Cyrus Field is once more on his way to this country, and that he brings with him an additional proposal from the United States Government for uniting the two continents by telegraph. We hope that so great and so necessary a project will meet with sufficient cooperation in England to soon render it an accomplished fact. Governments as well as peoples would gain by a successfully-laid cable; and, consequently, Governments as well as companies should encourage the work. We shall have more to say on this subject soon.

The question of the fouling of iron ships has not attracted the attention of the Admiralty and of scientific men as it deserves; and if some remedy be not found for the evil, it becomes questionable whether iron ships are improvements on wooden ones. We find that the bottom of the Resistance, when placed in the dock at Portsmouth, on Tuesday last, was in an extraordinary condition; in fact, it was as foul as if the vessel had gone on a long commission instead of being on the home station. The entire bottom was covered with weeds and grass, patches of mussels were on the port side, together with a good sprinkling of barnacles. On the starboard side the barnacles extended from stem to stern, with weeds and grass in some places three feet in length. The mussels extended fore and aft, with barnacles as large as a child's head. It is, in fact, surprising how such foulness could have accumulated in so short a space of time. It was not because precautionary measures had not been taken. The ship's bottom was originally coated on each side with different protective compositions. On one side the composition was entirely destroyed, and patches of rust, more particularly under the quarter, had eaten their way through. It may be well said, that if the waters of the Medway thus foul our iron ships, despite the protective coverings given them, it is no place for the construction of docks and basins for their special reception. A few thousand pounds expended on scientific experiments would certainly throw some useful light on this important question. Mr. Mallet has some valuable information to communicate on the subject, and our readers know that we have more than once urged the Lords of the Admiralty to experiment on Mr. Grantham's plan, which has been so strongly recommended, and which no doubt would assist in solving a most difficult problem.

From an announcement in a San Francisco paper, we learn that ten floating batteries on the plan of the Monitor, with turrets, are in process of construction, and that workmen are employed on them night and day. They are all to be larger than the Monitor, and with such improvements as experience has thus far suggested. A Californian correspondent says that these vessels are intended for operation on the Atlantic coast, and are but a tithe of the measures, offensive and defensive, in progress in the East. The boat for San Francisco is to be built there, and to cost 120,000*l.* The wooden portions are to be constructed of Californian timber—oak or laurel—probably of both. She is to be an improvement on her prototype—the Monitor of Ericsson. She is to have a turtle-back deck, and to have hot water arrangements for scalding boarders. The systematic misrepresentations of America and American institutions and habits by the press of this country, have already produced their natural fruits on the other side of the Atlantic. The hatred against England is as strong in California, according to the *Times* correspondent, as it is in New York. The Northerners *everywhere* appear to be animated by one passion—that of intense hatred towards England. We sincerely hope that this feeling will not last, and that when Americans reflect on the calm and dignified attitude of our Government they will meet with something like contempt the calumnies of many of our public men and the majority of our newspapers. The "leading journal," which has done the most to produce this bad blood, is pretty sure to suit its tactics by the general events of the war. When the Southerners were successful, about twelve months since, the Northerners were sneered at; when the tide of fortune turned in favour of the North, the North was respected, and even complimented, for their "extraordinary vigour" and "multitudinous "efforts on land and water." Immediately M'Clellan was repulsed, the old spite against the North and everything northern manifested itself in malignant intensity. Should the Southern forces be again beaten, a different standard of criticism will be adopted. Success, as usual, will be worshipped. Our only hope is that the fratricidal war will soon be terminated; and, when terminated, we should like that both North and South, whether divided or united, may say that, during the mighty strife, both the English Government and the English people remained neutral in their conduct, and impartial in their criticism.

The accounts of the Metropolitan Gas Companies for the year 1861 have just been issued, pursuant to the 41st section of the Metropolis Gas Act. They show that the total paid-up capital of the thirteen companies amounts to 5,647,900*l.* The total income derived from the sale of gas was 1,385,592*l.*, being a considerable advance upon that of the previous year; and it is believed that the present year will exhibit a still further increase of revenue. The principal item of expenditure, that of coals, was 728,552*l.*; but this sum was reduced by 335,302*l.*, or 46 per cent., by the sale of coke, tar, and ammoniacal liquor. Several of the companies return their bad debts and allowances at 5,108*l.* on a rental of 574,901*l.*, being less than 1 per cent. The dividends which the companies have been enabled to pay have ranged from 6 per cent. the lowest to 10 per cent. the highest. It should seem that the companies are all in a highly prosperous condition; and the only one of them that appears in the creditable position of having given the consumer the benefit of its prosperity is the South Metropolitan, which is supplying its customers at 4s. per 1,000 cubic feet. It is evident that gas of great purity and of a high illuminating power ought to be supplied at a cheaper rate; and it is hopeful to find that several of the companies are approaching that point in the accumulation of reserve funds, which will bring them within the operation of the limitation clause of the Act, when gas consumers will be enabled to share in their prosperity.

The attention of the scientific world has lately been called to the balloon ascents of M. Glaisher, and several interesting facts have been brought to light which deserve to be recorded. It appears that when the voyagers reached the clouds, they found themselves surrounded with a dense mass of moisture, about two thousand feet in thickness, which, being passed through, a beautiful clear blue sky presented itself, with the mass of clouds floating below. After this, being above a mile and three-quarters from land, they could not perceive any clouds, but the air seemed to possess such expansive power that the balloon shot up very rapidly, so that M. Glaisher failed to obtain a photograph of the scene below. Several pigeons were thrown out, but dropped as heavily as a stone. Blindness began to be felt at five miles' altitude, and M. Glaisher's last entry of the thermometer was *minus* five, or thirty-seven below the freezing point. Subsequently he saw, but was unable to register, the barometer at 10°, after which he became almost unconscious; and when they had attained an altitude of six miles Mr. Coxwell's hands turned black and he began to faint. M. Glaisher then recovered sufficiently to hear his companion say, "I have lost the use of my "hands: give me some brandy to bathe them." The temperature was then below zero; and the water in the vessel supplying the wet-bulb thermometer was one solid mass of ice. At this point, the aeronauts seemed to incur great risk; for while M. Glaisher could not move,

Mr. Coxwell was seized with intense cold, and everything seemed now to depend upon the latter gentleman, whose self-possession and ease seemed wonderful. M. Glaisher says, "it "was quite characteristic of Mr. Coxwell," for he had never seen him without a ready means of meeting every difficulty when it has arisen; and so it proved, for just at this juncture, as the hoar frost surrounded his neck, and his hands were helpless, he seized the line between his teeth and pulled the valve open until the balloon took a turn downwards.

The height attained was certainly unprecedented, and from the description which has appeared in the daily papers, written by M. Glaisher himself, it seems to have been attended with no ordinary danger. M. Glaisher wisely concludes his interesting scientific notations by observing, that "it would seem from "this ascent that five miles from the earth is "very nearly the limit of human existence. "It is possible, as the effect of each high "ascent upon myself has been different, that "on another occasion I might be able to go "higher, and it is possible that some persons "may be able to exist with less air and bear a "greater degree of cold; but still I think that "prudence would say to all, whenever the "barometer-reading falls as low as 11 inches, "open the valve at once; the increased in-"formation to be obtained is not commensurate "with the increased risk."

MILITARY TRAINING IN FRANCE.

France is unquestionably the greatest military power in the world, whether judged by the number or the efficiency of the men she is able to bring into the field. Every man is more or less a soldier, and every soldier undergoes a system of training calculated to develope the highest physical and mental qualities of which he is capable. In her nine establishments for military education, she has constantly a large staff of officers and men undergoing a system of education of the highest order in every department of military study, and from these institutions she is continually sending forth to the various stations in which her immense army is located bands of well-trained men and officers, whose duty it is to impart the benefits of their special education to every officer and private of which this vast army consists. There is one branch of military knowledge in which every French soldier excels; and whether we look upon it in a sanitary point of view, or as rendering the soldier in the highest state efficient when called into active service, or as exhibiting the high developement of which the grand human machine is susceptible, its study is equally interesting and important: we allude to the gymnastic exercises of which the French soldier is capable, as the result of well-regulated systematic training. The attention of our high military authorities has been called to this subject, but, so far as our knowledge goes, there is little or no improvement upon our old drill routine. The mortality in the English army is said to be greater than that of any in Europe. Why should this be so? True it is the climate of some of our colonies is unfavourable to the health of the European, but the increased mortality is not confined to those regiments which are sent on foreign service. We have certainly the best fed, the best clothed, the best housed, and the best paid army in Europe; and if regular diet, regular discipline, and regular hours do not produce a lower rate of mortality in military than is found in civil life, we should seek out the cause and provide, if possible, the remedy; and we are decidedly of opinion that the adoption of some such system of gymnastics as that practised in France would not only tend to make our soldiers much more active and self-reliant in a campaign, but greatly to diminish the present rate of mortality. We will, therefore, furnish an outline of the system pursued at the Ecole Normale de Gymnastique, at the Redoute de la Faisanderie, near Vincennes, where three professors of the science and art of gymnastics, under a commandant, regularly train about 300 men and officers, the course extending through a period of six months, these men and officers acting afterwards as "monitors" or instructors in their respective regiments and battalions.

The gymnastic exercises are divided into five lessons, of which the first and second are elementary, and the last three, gymnastics applied to special purposes. The men are divided into three classes, the third consisting of recruits, the second of men who have passed the elementary course of a fortnight, which every recruit undergoes, but are not sufficiently proficient to commence the extended course of the first class. The following is a standing regulation:—"None but the "prescribed exercises are permitted by the "instructor; he must never allow the men to "attempt any extraordinary or exaggerated "feats of strength or dexterity that might "cause accidents or injure the soldier. His "aim must be to develope the strength, agility, "and dexterity of the soldier by a wisely re-"gulated exertion, and inspire him with that "self-confidence and energy which the various "occasions of his military life may demand. "He must strive to rouse the pluck and emu-"lation of the men by rendering the exercises "as agreeable and as easy as possible, taking "all necessary precautions to prevent them "from injuring themselves or becoming dis-"couraged. He must never forget that the "perfect safety of the soldier under training, "the pleasure of the various exercises, and, "above all, the soldier's own desire to excel, "are the first and secret elements of suc-"cess in gymnastics. Harsh treatment must "be carefully avoided, much more anything "like turning his efforts into ridicule when he "fails, or punishing him for involuntary "awkwardness. Nor must he be required to "maintain a strictly military attitude in these "exercises, which will only uselessly fatigue "him, as far as our object herein is concerned; "nor must we check too severely those spon-"taneous manifestations of enjoyment and "humorous delight which he may betray, "since they are but the natural and, indeed, "fortunate results of the exercises when pro-"perly directed. In conclusion, we must not "expect more than regularity, precision, and "relative perfection in these exercises, to "which a military form has been given merely, "to facilitate their study and their application "to the whole army."

The men being drawn up in fatigue dress, and in squads of ten or fifteen, commence with those exercises calculated to impart suppleness to the entire body. They consist of turning the head to the right or left, forwards and backwards, and *vice versâ*, the body always maintaining the erect position. Then the body is bent forward, the arms are raised vertically and sideways with and without bending them, flung out singly and together with fists clenched, or circles are described from the shoulder, the arms being the radii. It has been said that French soldiers march more easily than those of any other nation, and this is attributed to the superior training which they undergo. There are three cadences or rates of marching in the French army. 1, The moderate cadence, consisting of seventy-six movements per minute; 2, the quick cadence of one hundred and fifty; and 3, the running cadence of two hundred movements per minute. In all the marching exercises the head, arms, and body have to be kept perfectly in their natural position; and the great desideratum sought is by bringing the toes to the ground first, to avoid that shaking of the spine and its consequently distressing action on the brain and lungs which invariably happens when the weight of the body is thrown upon the heel; a rhythm is given to the performance and a beneficial action exerted upon the chest by the men being made to repeat *one, two,* as each foot respectively touches the ground. The maintenance of the equilibrium is secured by causing the soldier to stand alternately on the right and left leg, bending in each case the other against his body with locked fingers, standing on one leg with the other bent behind, or by coming slowly to the kneeling position, then springing up smartly, flinging the arms suddenly above the head, the nails turned inwards, and, lastly, by bending forward or backward, or to the right or left, on one foot. The full developement of the muscles is secured by a variety of means. At the word of command the men smartly strike the breast with the left and right hand alternately—strike out as in boxing—support cannon-balls in one or both hands with arms extended—fling an iron bar grasped in the middle—support, poise, and swing a heavy club in every variety of position. As a preliminary to leaping exercises, they are made to hop on the right or left leg singly, and then alternately on both, to walk on the heels alone or on tiptoe, and to give the body its proper inclination in ascending and descending, by being carefully trained to throw the weight of the body in the former on the toes, and in the latter on the heels. Wrestling in every possible form is systematically taught. The men, provided with short cords, to the ends of which appropriate handles are attached, pull against each other in pairs or in groups; or two sit on the ground, close the legs feet to feet and sole to sole, and then, with the cord just mentioned, strive each to raise the other. The victors then go through the same exercise with each other, until only two remain, the strength of whom is ascertained by a dynamometer, and the results are carefully noted. The last preliminary exercise consists in causing the men to pull against each other, in pairs or groups, against a fixed point or a dynamometer which will indicate the force of the combined pull. Most of these exercises admitting of a rhythm or cadenced sound, such a practice is encouraged, which not only imparts animation to the scene, but tends to increase the power of the chest; and, as the harmonious utterance of martial sentiments and patriotic songs tends greatly to promote the *morale* of the soldier, singing is systematically taught in the French army; and it is said that even difficult concerted pieces are so accurately sung, that an eye-witness of one of these exercises declared "that the whole seemed, as it were, an organ "of human stops, alto, tenor, and bass har-"moniously blending."

The preliminary exercises being mastered, the men are next drilled in "applied gym-"nastics," and here, if possible, still greater caution is exercised to preserve the men from the danger arising from imprudent efforts, an unhealthful spirit of rivalry by emulation, and the discouragement apt to follow from repeated failure. No leaping requiring violent effort is permitted in cold weather, nor is any

man not perfectly disposed required to practise leaping at any time. The object of the leap must be increased gradually, and a downward leap must never exceed sixteen feet.

At the word "attention" the soldier prepares for the exercise, at the word "forward" he closes the points of his feet, then at the word "leap—*one*," he stoops in his lower extremities, slightly raising the heels, stretching his arms to the rear, with the fists clenched; he then rises again, his arms hanging naturally down. At the word *two*, he repeats the movement. At *three*, he recommences the same movement, vigorously stretches the hams, throws his arms forward, leaps the distance or over the obstacle, falls on the point of his feet in a stooping posture, and then resumes the position of attention. The same principle is observed in all leaps, the position of the arms simply being changed according as the leap may be to a height, downward, or forward and downward. The running leap is similarly performed, the pace being quickened up to the moment of making the spring, which, where excellence is obtained, usually carries the body a distance of from fifteen to twenty feet. This power acquired, it is practised by the men in heavy marching order, that is, with their arms and baggage; but in such cases the downward leap is restricted to thirteen feet, and great care is taken so to adjust the arms that neither they nor the men may be injured. Advanced to this stage, the very difficult exercise of leaping from or to a body in motion, or both bodies in motion, is taught, the principle being that the body in oscillation must be quitted as it is rising, and that the leap to a body in motion should be made as it is sinking.

The soldier is familiarised with nine rules, which he is taught to apply spontaneously in those circumstances where leaping may be required unforeseen, and prompt decision rendered necessary. 1. To form a rapid judgement of the obstacle, and also of the ground on either side of it. 2. During the leap to restrain the breathing, and to make the expiration of the air with which the lungs have previously been filled the moment he reaches the ground. 3. In leaping where width and height have to be overcome, to fling out the clenched fists in the direction the body is to take, so as to augment the impulse given by the legs. 4. In downward leaps to raise the arms vertically as soon as the body begins to descend. 5. During the whole time of the leap to keep the arms in the parallel position they have at its commencement. 6. In forward or wide leaps to incline the body forward. 7. To fall on the point of the feet, the legs close together, bending all the articulations of the body from above downwards. 8. To avoid too rough a fall, by giving to all the articulations a general and supple setting up, so as to make a light bound on landing. 9. On landing, to avoid all useless motion, and allow the muscles to relax, as their continued contraction and rigidity would interfere with the equilibrium of the body. Leaping with poles is practised, the shortest being about the length of a rifle, and the longest about twelve feet. Skill in this style of leaping depends upon the energy of the effort and the length and rapidity of the run. Perhaps one of the most useful exercises to the soldier is that training which enables him to suspend the body by the hands, the elbow, the legs, or by one hand, one leg, or even one finger; great strength of muscle is the necessary result, apart from its advantages in certain military operations. Raising himself up a rope "hand over "hand," walking, running, poising, meeting and passing on horizontal beams, raised at different heights from the ground, without a balancing pole, with the beam inclined or set in motion, are parts of the every-day drill in the French army. Little Nathalie and Blondin's are only extraordinary manifestations of what every soldier in the French army is taught as a necessary part of his military education. The principles of the art of swimming are so successfully explained, the various positions and motions the body should assume and make in the water, that it not unfrequently happens the men can swim the first time they enter the water.

Great scaling ability is essential to every soldier, and in this matter particular attention is paid to the education of the French army. By nine different modes the men are taught the use of the scaling ladder, whether of wood or rope, and, where such ladders are not at hand, to apply the tent-pole, or any other pole, as a means to enable them to scale the walls of an enemy; nay more, as a result of the strength imparted to the muscles and joints by the suspension-bar exercise, they are trained to mount the parapet of an enemy by means of the feet, hands, and fingers alone. The walls of every beleaguered city, or the front of any battery that has been stormed, will be sure to present on its surface indentations produced by the shot, shell, and bullets of the besiegers. By means of these holes the French soldier is taught to raise himself like a cat or a monkey, so as to mount the parapet and commence the hand-to-hand encounter with his foe; nay, should no such *points d'appui* present themselves, then the men are trained to overcome the obstacle by making pyramids of themselves, and mounting, "in the twinkling of an eye," by means of each other, to the point so honourable in the soldier's estimation. The trapéze of the acrobat has been introduced as affording an excellent means of strengthening the arm and the eye, and imparting that very necessary quality self-reliance, and it is said that some of the swinging leaps made by the men are simply "prodigious." A soldier is required not only to be capable of bold daring and rapid movement, but also to undergo laborious exercises of another character. These are not overlooked in the gymnasium. The men are trained, by judicious gradations, to carry at the top of their speed all the implements of war, such as fascines, sand-bags, gabions, projectiles, &c., or sacks filled with sand, each sack weighing fifty pounds; also ladders, beams, caissons; to drag gun-carriages, to improvise litters, to carry with rapidity and skill the wounded from the field. They are also practised in the elements of boxing and fencing, and in sword and bayonet exercise. The cavalry are, moreover, drilled to leap on their horse from the rear whilst galloping, to leap over a hedge or barrier together with him, the man being on foot and holding the reins: few, perhaps, attain to this, but those who aim high never hit low.

It is some such system as this we should like to see adopted in our own army, and applied, with certain modifications, as a necessary part of physical education in our colleges and public schools; nay, we would go farther, and urge the erection of suitable gymnasia in all our large towns, and, where the district is sufficiently populous, in the various townships of the country. *Cui bono*? it may be asked. What are the advantages which would accrue? These we will now consider, both as regards the soldier and the civilian.

1. As regards the soldier: As before noticed, it has been said the mortality is greater in the British than in any other army in Europe. There is no need that it should be so; in fact, if such be the case, it is a national disgrace. No soldier is better fed, better clothed, and, we may say, owing to our recent barrack improvements, better housed, than the British. Why, then, this mortality? Considered merely in a sanitary point of view, we think the adoption of a judicious system of gymnastic training as an essential element in military education would have a tendency, not only to develope the physical powers of the soldier, but greatly to prolong his life. What is the present routine of a soldier's life in barracks, at home at least? A few hours' drill a day, parade, and then many unemployed hours, the *ennui* of which the soldier seeks to remove by a visit to the canteen, or to the lowest class of beer-houses, and even to still more questionable places of resort. That very great and important steps have been taken by the authorities to improve the physical and moral condition of the soldier is undeniable; such as the formation of camps, the establishment of schools, libraries, and savings' banks; and great good in special instances has no doubt resulted: but temptation follows the soldier to the camp, and much money that might, under an improved physical training, be saved, is squandered in yielding to these temptations. Book-lore can never become a general object of pursuit in the army; the men who enlist are generally from that class who have not had the advantages of elementary education in early life, and have, consequently, little or no taste for learning; moreover, those who may, have but a very faint gleam of hope of being able thereby to raise themselves from the ranks, let their acquisitions be never so varied and solid. All soldiers, however, would delight in those exercises which would give them a physical superiority; they would recognise in them objects worthy of a soldier's best study; they would strive to excel; their minds would be relieved from that *ennui* which now oppresses them; and, in the same ratio, the temptations of the canteen and the town would become weakened. Men so trained would be physically stronger, morally elevated, and, as a necessary consequence, longer lived.

But the three hundred various gymnastic feats and practices in the French army are pursued with the direct object of specially qualifying the men for the possible and probable casualties of war, and they succeed in imparting to the men that self-reliance, and that important self-conceit of their own powers, that, believing themselves to be the best soldiers in the world, they invariably enter upon the field of battle with the conviction that they can conquer, and, with such a consequent determination to do so, that the victory with such men is half gained ere the din of battle has begun.

In ancient warfare, the hand-to-hand struggle decided the conflict. The invention of gunpowder and the use of artillery subsequently caused battles to be fought at an increased distance between the combatants; but it is now more than probable that the very perfection to which *armes de precision* have been brought, will render it necessary either to limit the use of the rifle and rifled field-pieces, or to trust more and more to the daring, skill, and, comparatively speaking, independent action of the troops. Accuracy and long range are the great advantages of modern arms; but these have been purchased at the expense of a flat trajectory and greater penetrative qualities at short ranges. The great curvature of the trajectory renders an exact estimate of the distance an absolute necessity in the use of the rifle. Amidst the din, confusion, and smoke of battle, the air filled with the yells of the combatants, the shrieks of the wounded, and

the groans of the dying, he must be more than man who can coolly sight his object and take that deliberate aim which the rifle requires; nor will it be practicable so to train any body of men as to calculate the shortening of the distance between them and their enemy by the movements of the latter, or their own, as to insure a fatal fire. "The modern arms," said the Emperor of the French in the Italian war, "are dangerous only at long distances." Such a distance may be overcome by a variety of stratagems before the opposing force has time to obtain the range; whilst, supposing the range to be obtained, and a volley fired, a re-adjustment of the sight would be necessary preparatory to a second discharge; and how is this to be done when the enemy, perhaps shrouded in smoke, is momentarily changing his position? It has been said that a body of cavalry dashing down upon a square would be advancing, when 500 yards distant, at the rate of four yards per second, and that *seven seconds* would suffice to carry them over the *dangerous space*, supposing the commander of the square to order the rifles to be sighted for 500 yards! It is clear, therefore, that the advice of General Trochu in the Italian war was sound. "If "you are charged by cavalry, wait till they "come up to forty paces, then fire and be ready "with the bayonet." Now, that soldier will be the best qualified to act under such circumstances that has, in addition to a judicious and sound course of training in the use of the rifle, been made most self-reliant and skilfully active by such a course of gymnastics as is prescribed in the French army.

2. As regards the civilian, the advantages will be at once apparent; leaving out the pipe-clay, or what is purely professional, would not the establishment of gymnastic institutions, as we have recommended, be an advantage to the country at large? Instead of the constantly-rising complaint, that owing to the injurious effects of many of our manufactures upon the health of our artisans, and the physical deformity and premature decrepitude consequent upon the children of the working classes being sent too early to injurious trades, we should be able to pride ourselves upon a stalwart, athletic race, with an increase of that self-reliance which is the glory of our countrymen, the bills of mortality would show increased longevity, and the morals of the people would be improved.

MILITARY DRAWING AND SURVEYING.*

It is no longer possible to obtain a commission in the army by means of wealth or influence alone. Every candidate must qualify himself for the profession by a course of study by no means light. Among other subjects which it is compulsory upon the candidate to know, are military drawing and surveying; the latter cannot be readily or efficiently acquired without a knowledge of the former; moreover, surveying requires practical instruction, whereas drawing may be acquired by the silent teaching of clearly-defined principles and rules, accompanied by well-executed examples. Such a work has been provided by Captain Patterson; and young gentlemen preparing for the army cannot possibly have a better guide to aid them in the work of self-instruction in this most important branch of their studies. To such we recommend the work, and, at the same time, take the opportunity of saying, that everyone studying the delightful art of sketching, either as a pastime or with a view to its exercise as a profession, apart from military life, will derive much instruction from the lucid observations of the gallant author.

* A Treatise on Military Drawing and Surveying, with a Course of Progressive Plates. By Captain William Patterson, Professor of Military Drawing at the Royal Military College, Sandhurst. Trübner & Co., London, 1862.

HORTON'S TIMBER, STONE, AND SUPERFICIAL TABLES.*

Architects, surveyors, and all persons requiring readily to ascertain the superficial or solid contents of unequal-sided, square-sided, octagonal-sided, or round masses, will find these tables exceedingly useful. They have been calculated with great care, are printed in bold clear type, and form, with the rules, explanations, &c., a compact small 8vo. volume of 319 pages. The errors of previous formulæ are distinctly pointed out, and the work is destined to supersede the erroneous books now in use, in which the popular work by Hoppus must be included. Everyone requiring such tables should at once purchase the book; and we endorse the opinion of Rees, quoted in the introduction, that as "Government has, in some instances, come forward to fix a standard of measure, as in corn, coals, land, &c., and as old prejudices can never be so successfully combated as by the authority of enlightened legislators, it is to be hoped that we may some day find this, and other topics of a similar nature, become the subject of Parliamentary investigation." The work is dedicated by permission to the Right Hon. Milner Gibson, M.P., &c., which is in itself a guarantee of its intrinsic value.

* The Complete Measurer. By Richard Horton. London: Weale, 1862.

THE ATLANTIC TELEGRAPH.

The *Times* of Monday last contained the following paragraph:—

"It will be recollected that some months since, at the instance of the Atlantic Telegraph Company, the Lords of the Admiralty ordered the paddle-wheel steam surveying-vessel Porcupine, 3, to be prepared for sounding that portion of the bed of the ocean, near Ireland, on which the electric cable, laid by Sir Charles Bright, is supposed to have broken. Officers of experience were appointed to undertake this important duty, and an efficient crew was selected from the surveying-ship Fisgard, 42, at Woolwich. The Porcupine was supplied with ample sounding machines, including those of the Bulldog pattern, which bring up some of the bottom each time they are used, and with a donkey steam-engine on deck for hauling them on board. The Porcupine left Plymouth for the scene of her labours on June 22, arrived at Galway on July 9, and departed therefrom on the 21st. She proceeded to what is termed the Cliff, about 200 miles west of Galway, and during her operations there experienced a heavy gale of wind, which carried away her rudder head. The Porcupine put back to Galway on July 26, had her rudder repaired, and on August 6 sailed for Rockall Bank, some 500 miles north-west of Donegal Bay, where she arrived on the 14th, and after remaining two days went into Killibeg's Harbour, Donegal, for fuel, and departed on the 24th for Queenstown, which was reached on the 30th. After staying till the 3rd inst., she returned to Plymouth. One of the objects of visiting the Cliff was to ascertain the exact nature of its declivity, considered to be above 1,200 fathoms in eight miles, or a fall within that distance from a depth of 550 fathoms to a depth of 1,750 fathoms. It is stated that the officers by sounding crossways have also discovered what the seamen term a 'gap,' through which a wire could be laid with less risk than where Sir Charles's wire was laid. They also discovered a steeper cliff, which they have named the Porcupine Rock. Some of the soundings extended to a depth of 2,500 fathoms. The visit of the steamer to Rockall on August 14 seems to have been prompted by a desire on the part of the Lords of the Admiralty to be able to judge by a knowledge of its depth and character of the expediency of dropping a cable across this bank, for the purpose of connecting Ireland with Iceland and America. On the ridge of the bank soundings varied from 90 to 160 fathoms; fish were most abundant; the bottom consisted of mud and sand. It is reported to be the opinion of several of the officers on board the Porcupine that a line of communication which can be established without the necessity of so long a wire as that direct across the Atlantic will be much more likely to succeed. A system of comparatively short lengths can be repaired with less difficulty in case of injury, besides which it is believed that with the present limited extent of telegraphic science there is no means of transmitting a message rapidly through a great length of wire. One word is said to overtake another, and it is averred that the force requisite to be exerted by the batteries for sending the fluid so great a distance must involve injury to the wire by the necessary intensity of the electric spark. The diagrams, returns, and reports from the officers engaged on board the Porcupine leave this afternoon for Whitehall for the consideration in the first place of the Lords of the Admiralty, after which communication will be made by their Lordships to the directors of the Atlantic Telegraph Company. The vessel is now at Keyham steam-yard, where she will disembark her sounding gear and machinery, and re-ship the deck-house, or office, displaced for the purposes of her recent duty. She will probably leave on Wednesday for Woolwich."

THE INTERNATIONAL EXHIBITION.

Fuel.

All substances used as fuel are of vegetable origin. There are three distinct varieties of fuel—namely, wood or other vegetable matter, peat, and coal. Everyone has seen a peat bog, which is obviously the result of the accumulation and natural decay of various plants. The bogs of Europe are chiefly formed of certain species of mosses, but in India and some other localities peat is derived from other kinds of plants. If a bog is examined it will be found that the degree of decay is proportionate to the depth: thus, at the surface the peat may consist of the tangled and only slightly altered remains of its component plants; while at the bottom, especially if the bog is deep, it may be a black earthy compact mass, presenting no sign of vegetable structure. Now, it may be shown that all coal, like peat, is the product of the natural decay of vegetable matter. It would be easy to select a series of analyses of peat and coal of various kinds which would illustrate in the most striking manner the gradual change in composition from wood to anthracite, which is the ultimate stage of decay, and consists almost wholly of carbon. Vegetable matter may be regarded as *virtually* composed of water, carbon, a small quantity of hydrogen not in combination with oxygen, and about 2 per cent. of ashes. Part of this water is only present like water in sponge, and may be easily expelled by heat; but the rest exists in combination as an essential part of wood. It is not, however, pretended that the oxygen and hydrogen forming this latter part are actually combined in the state of water. The heat produced by the combustion of wood is derived solely from the carbon, and from the hydrogen in excess beyond what is required to form water with the oxygen present. All the water supposed virtually to exist even in the driest wood not only does not yield heat, but occasions considerable loss of heat, inasmuch as it must be evaporated during combustion at the expense of the heat developed by the burning of the carbon and the excess of hydrogen above-mentioned. These remarks apply equally to peat and coal. It has been ascertained by experiment that the oxygen in these fuels may practically be considered as in combination with hydrogen in the state of water, in so far as relates to generation of heat. The ultimate products of the *perfect* combustion of fuel in atmospheric air are water and carbonic acid; but, if the combustion is not perfect, various secondary products are formed, such as tar, hydro-carbons, &c. When wood, peat, or coal is exposed during a sufficient time to a red heat in a close vessel, like a retort, combustible gases and vapours are driven off, leaving a black residue, which in the case of wood and peat is termed charcoal, and in

the case of coal is termed coke—substances with which everyone is familiar. Even in open fires charcoal and coke are always formed after short ignition. When charcoal or coke is burnt in atmospheric air, carbonic acid is immediately formed; but when this gas passes through a stratum of redhot carbon more than a few inches in depth, it takes up a portion of carbon, and is converted into twice its own volume of a combustible gas termed carbonic oxide, which burns with a beautiful blue flame, producing carbonic acid. Hence, in any furnace or closed fireplace having a grate at the bottom, and containing red hot fuel, carbonic oxide will always be formed, for there is a continuous current of air upwards through the grate, and, as has been stated above, carbonic acid is always the immediate result of the contact of atmospheric acid with incandescent carbon. Carbonic oxide gas gives out on combustion a very large amount of heat, and is now applied with the greatest advantage to many important purposes. If, through an imperfect supply of air, much of this gas is allowed to escape into the furnace chimney, as is frequently the case, there will be a great waste of fuel. We are anxious to fix particular attention on this gas, as in the sequel we shall have occasion to point out very valuable applications of it in metallurgical operations connected with iron. We cannot in these columns enter into much detail on the subject, however important it may be, but we earnestly advise our metallurgists to lose no time in studying what has recently been written on the matter.

The first subject which naturally presents itself for special consideration is peat. Not much is to be learnt from the display of mere lumps of raw peat; yet in the present Exhibition there are several illustrations connected with peat of great practical interest. There is only one metallurgical process in Great Britain in which, so far as we are aware, peat is directly applied as fuel, and in that only partially—namely, the smelting of lead in the "ore-hearth." This method is extensively employed in the North, and in the case of rich ores is maintained by some experienced smelters to be superior to every other. It is a singular circumstance that in former times it was practised successfully in Derbyshire, where it became extinct; and that attempts to reintroduce it into this county have signally failed.

In the state in which peat is usually obtained after desiccation in the air, it is quite unfit for the smelting of iron and various other metallurgical operations. It is a light, porous substance, which, in comparison with other kinds of fuel, contains only a small quantity of combustible matter in a given volume. Very numerous attempts have been made to render it more generally available as a fuel, both in this country and on the continent; and the records of trials which have been published on the subject are not a little conflicting. Peat has an extensive literature of its own, which is amusing as well as instructive. All attempts hitherto made to render peat suitable as a fuel for metallurgical purposes have had reference either to its condensation, by compression or otherwise, or to its carbonisation. In order to effect the compression of peat, numerous contrivances have been devised, and, as usual, patented; and at the present time much attention is directed to the compression of peat. The peat is reduced to pulp in a sort of pug-mill or other suitable machinery, and is afterwards drained and moulded into brick-shaped pieces, either with or without pressure. The peat thus acquires great solidity and a much higher specific gravity. But this treatment is necessarily so expensive as to render its adoption impossible where coal abounds. In some countries, however, such as Sweden and Bavaria, it is practised with success. In Bavaria, peat bricks are extensively used under locomotive boilers, and in Sweden Ekman has long employed peat in his gas-welding or reheating furnaces; it is fashioned into bricks, and subsequently dried by artificial heat at a temperature almost sufficient to cause incipient charring. Under No. 21, in the Swedish department, will be found specimens of iron manufactured in such furnaces, with prepared peat as the fuel, by Baron Hamilton, Nericia, at whose works the annual consumption of peat for this purpose is between 600 and 700 tons. In the Italian department, Gregorini exhibits steel made in a gas-puddling furnace with peat and lignite as fuel, No. 52. Furnaces constructed on this principle, whether for the use of peat or other kinds of fuel, are well worthy the attention of our ironmasters and other practical metallurgists who are interested in economising fuel. We have a strong belief, which has grown with the experience of many years, that these furnaces will one day—and that not far distant—play an important part in the metallurgy of this country. Without the aid of diagrams it is impossible, we fear, to present such a description of them as shall be satisfactory to the general reader. We will, however, make the attempt; but we must assume that he is acquainted with the form and action of a common reverberatory furnace, such as may be seen in operation in many parts of England. Instead of the usual fire-place, there is what is called the "gas generator." This consists of a circular chamber of fire-brick several feet deep and two or three feet in diameter, closed at the bottom, and having a hopper at the top, through which fuel is supplied. This chamber, at a certain height from the bottom, is in direct connexion with the body of the furnace, so that flame may issue as freely from it as from the fire-place of an ordinary reverberatory furnace. In the sides of the generator, at a certain distance from the top, are a series of three or four small round holes on the same level, and at some distance lower down is another similar series of round holes. These holes are for the passage of the air intended to support combustion in the interior of the generator, which is blown in either by a fan or some other convenient blowing machine. Now, when the generator is full of incandescent fuel, and air is injected through the lateral holes, carbonic oxide gas is copiously produced and passes into the furnace, as there is no other place of egress, the hopper at the top being supposed to be shut. As it escapes from the generator, it is met with a current of heated air, or, as it is technically termed, "hot blast," which is injected downwards from the roof of the furnace at or near its junction with the generator, either in several jets or in one continuous sheet. The carbonic oxide while still hot is thus burnt, and the heat developed is sufficiently intense even to melt wrought iron by the hundredweight. The air which supplies the generator is also previously heated; and, in the Swedish furnaces, the apparatus for heating the blast consists of a series of cast-iron pipes fixed at the lower part of the stack. Hence, only the waste heat of the furnace is employed for this purpose. It is usual to place a hollow cylinder of iron round the generator, so as to leave a closed space between its internal surface and the exterior of the generator; and into this space the hot blast is introduced, whence it passes through the two rows of holes previously described into the interior of the generator. The atmosphere of such a furnace can be rendered either reducing or oxidising at will by regulating the amount of blast. At the bottom of the generator is a door, by means of which the ashes or clinker from the fuel may be withdrawn. These furnaces can be so modified as to suit any kind of fuel. We have the conviction that they would be well adapted for the free-burning coal slack of South Staffordshire and South Wales, of which enormous quantities continue to be wasted, and especially for anthracite. This kind of coal gives intense local heat; but this inconvenience might easily be remedied by introducing along with the air into the generator a certain proportion of steam. This steam would be decomposed with the formation of carbonic oxide and hydrogen gases, and some carbonic acid, and a considerable reduction of temperature would be the result. But the heat thus removed from the chamber would be subsequently restored in the body of the furnace by the burning of the combustible gases derived from the decomposition of the steam; so that there would be no loss of heat, but only a transference of it from the generator, where it is not wanted, to the furnace where it is applied. We are induced to occupy so much space with this subject, because we believe it to be of great practical importance to this country, and because ineffectual attempts have been previously made to attract the attention of ironmasters and others to its consideration. The fact is, our mineral fuel has been so abundant, and so easily accessible, that it has been most cruelly wasted. But matters are not quite so smooth as they used to be, and necessity is beginning to compel attention from our ironmasters to the subject of economising fuel in every possible way. The old reverberatory furnace is only a clumsy sort of gas furnace; but in those such as we have just attempted to describe, the fuel is converted into combustible gas, which may be applied under most advantageous conditions. It would be possible to generate carbonic oxide to any extent at a cheap rate, and to lay it on to houses for use as fuel, much in the same way as coal gas is now supplied for illumination. Indeed, it is daily so applied in many of our large ironworks, and with the best results. There would, of course, be many practical difficulties to overcome in rendering it subservient to domestic use; but there is no reason to apprehend any insurmountable obstacle. It would be probably necessary to have numerous gas generators distributed here and there in the case of large towns. It must be borne in mind that this gas has no offensive odour like that of coal gas. Fancy a smokeless London! The smoke of London is chiefly caused by domestic fires. This is not a mere chimerical notion. We believe the thing to be possible, and that one day this desirable result may be attained through the agency of gaseous fuel, though we may not live to see this devoutly-to-be-wished-for consummation. But a patent stops the way. Some years ago a monopoly was granted for such an application of gaseous fuel to an individual, who, we will venture to affirm, has never made an experiment on the subject from that day to the present, if, indeed, at any time before. Suppose any enterprising person were to succeed in bringing that scheme to a successful issue, and to apply it practically, the patentee, armed with all the terrors of the law, might pounce like a vulture on his prey, and carry off the spoil. Such is our present patent law, which, it is to be hoped, will be purged from its manifold defects during the next Session of Parliament.

Many attempts have been made to substitute peat charcoal for wood charcoal in the smelting of iron; and some time ago we were informed that an experiment of this kind was about to be again tried in Ireland. We examined some of the charcoal, which was dense and resisting, and yielded a white residue on incineration. The promoters of this undertaking were sanguine of success. We sincerely hope they will not be mistaken, though we must confess that under the existing relative conditions of Great Britain and Ireland we have strong misgivings as to the result. The machine which it was proposed to employ may be seen in operation in the Western Annexe, No. 1,562. It is described as Brunton's in the official catalogue; but the attendant assured us that it was the invention of a Mr. Buckland, formerly of the Maesteg Iron Works, South Wales. It consists of a solid obtuse iron cone, having a spiral groove on its exterior, and revolving vertically within a hollow cone of iron plate perforated everywhere with small round holes just like a colander. The peat is put into the space between the solid and hollow cones, and by the revolution of the former is forced in worm-like pieces through the holes in the latter. Thus prepared it is fashioned into bricks by any convenient machine, of which one is shown in juxtaposition. The bricks are artificially dried, and portions of them which are exhibited are solid and resisting. Peat charcoal prepared from them is also shown. A series of these specimens will be found in the Eastern Annexe, No. 43. Moulded peat charcoal and various products obtained from the destructive distillation of peat are exhibited in the same Annexe, No. 240. Some years ago, it may be remembered, very sanguine views were entertained and promulgated as to the great industrial advantages which were likely to accrue to Ireland by the manufacture of paraffine and other products

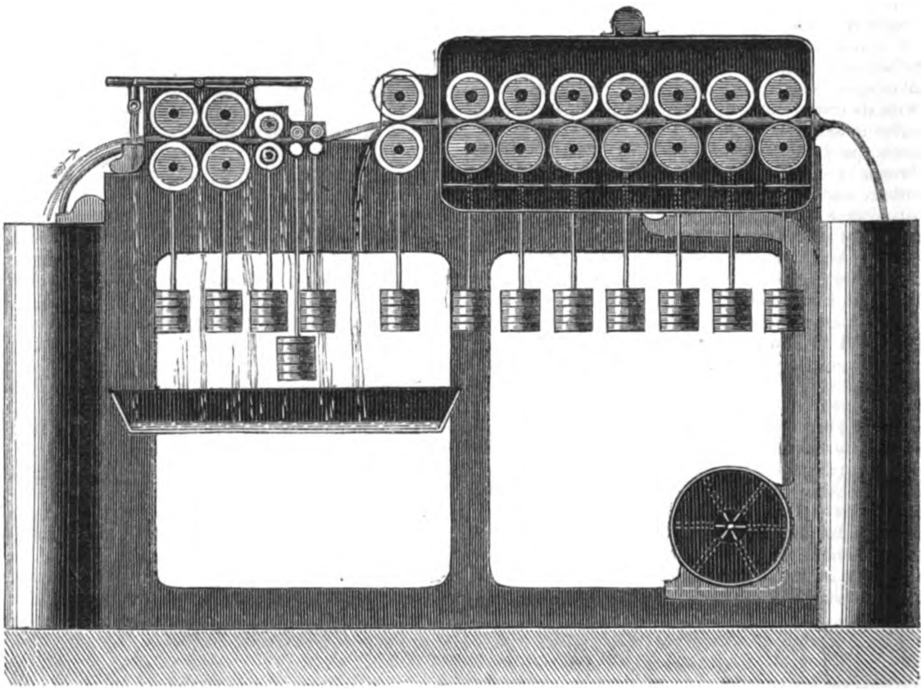
from peat. The present Exhibition is rich in examples of this exquisitely beautiful substance, which is delicately white, inodorous, and insipid, and which is now extensively employed as a substitute for wax in candles. It is obtained from certain varieties of coal, such as *cannel*, by distillation at a low temperature; and, though some might be produced by similar treatment of peat, yet the quantity would be very minute compared with what would be yielded by the above-mentioned varieties of coal. Attempts were actually made on a considerable scale in Ireland to manufacture this and other substances from peat, and the result was, commercially at least, unsuccessful. Anyone who wishes to inform himself on this subject may consult a small Parliamentary blue-book, with the following title:—"Report on the Nature and Products of the Process of the destructive Distillation of Peat, considered specially with reference to its Employment as a Branch of Manufacturing Industry. Made to the Right Honourable the Chief Commissioner of Woods, by the Director of the Museum of Irish Industry. April 8, 1851." In this period of crippled trade and cheap money, all sorts of schemes of "profitable investment" may be proposed to the British public, and among them, possibly, peat-bogs may be presented as inexhaustible sources of wealth. These bogs are often very extensive and deep, and in the present condition of this country with respect to mineral fuel are more likely to swallow up treasure than to yield it.

We now pass to the consideration of coal. Everyone fancies that he knows what coal is, but let anyone try to define it, and he will find himself immensely puzzled. In proof of this difficulty we may refer to the famous Torbanehill case, which was tried at Edinburgh in 1853. The published report of this trial occupies 246 quarto pages, and the point at issue was a definition of coal. A host of witnesses were examined, including many of the leading scientific men of the United Kingdom, and never was testimony more hopelessly conflicting. An agreement as to the exact meaning of the term coal was quite out of the question. The Judge took the commonsense view of the case, and properly ignored the so-called scientific evidence altogether. Some men of science, it is to be regretted, are too apt to present themselves in courts of justice as advocates, and not as impartial witnesses. This ought not to be. That which is a duty on the part of a legal professional advocate is a disgrace to men of science. We have heard evidence given by so-called men of science, sworn to speak the truth to the best of their knowledge and belief, which made us blush for their dishonesty. It is high time that the true followers of science should combine to put an end to the disreputable practice which at present exists. We have discussed this subject with members of the Bar, and even of the Bench, and we find that a strong opinion prevails as to the necessity of alteration. But what is to be done? Would it be desirable that the Court should appoint its own scientific witnesses, instead of relying upon the too often interested testimony of the witnesses subpœnaed by principals in an action at law? There are, no doubt, objections to such a course, but we venture to raise the question, which is one of great importance, especially in connection with patent law amendment.

Some years ago we were present at the Geological Society of London, when a discussion arose as to the definition of "coal." Sundry bad jokes were made, such as references to *Burns' Justice*, *Coke upon Littleton*, &c., when the distinguished Professor of Geology at Oxford put an end to the debate by stating—"Gentlemen, what we call coal in Yorkshire is raised from the bowels of the earth, is used as fuel, and sells for 5*s.* a ton."—*The Times.*

Three reefs have just been discovered amongst the Friendly Isles in the Pacific; two were discovered by Her Majesty's sloop Pelorus, and the other by a whaler. The sea is quite warm in the neighbourhood of the reefs, and sometimes appears like a boiling cauldron, which proves subterraneous fires are near.

MARSHALL'S MACHINE FOR THE PREPARATION OF FLAX, &c.



The object of this invention is to effect a better and finer division or separation of the fibres of the material to be spun. For this purpose, the flax, hemp, or other material is passed either whilst in the raw state, whether before or after being steeped, or when in a continuous sliver after having been heckled or carded between several pair of rollers, with an increasing draft as the material advances. This is effected by giving an increased rapidity of revolution to the second pair of rollers through which the material passes as compared with the first pair, the third pair in like manner revolving more rapidly than the second pair, and so on, constantly increasing the rapidity of revolution of the rollers as the material advances. The number of pair of rollers to be used, and the distances between the several pair of rollers, will be varied according to the requirements of the material to be operated upon, and the subsequent operations to which it is proposed to subject it. In addition to passing the material through the rollers, it is saturated thoroughly with water or other suitable fluid. After the material has been thus treated, it is dried and softened by passing it between rollers heated by steam or other suitable means. With this an apparatus may be combined for forming the material by well-known mechanism into a lap suitable for feeding it on to carding engines.

ON THE REMAINS OF EARLY BRITISH TIN-WORKS.

At the annual meeting of the Cambrian Archæological Association at Cornwall last week, Dr. Barham read the following interesting and valuable paper on the Remains of Early British Tin-Works:—

These notes by no means represent the subjects which I desired to lay before the meeting: they are but a slight outshadowing of them, and I place them in your hands simply to call attention to a few points which appear to me to require closer investigation than they have yet received. I shall leave with you the question of the intercourse of the Phœnicians, merely expressing my opinion that a great mistake has been made in supposing the Scilly Islands to have been the *Cassiterides.* There does not exist in the islands any indications of ancient tin-workings. I cannot learn that any tin has ever been found in any of the Scilly Islands. I know that small veins of schorl have been mistaken for tin. The appearance, however, of Cornwall from the sea is such that it might easily have been taken for a group of islands; and when we have the evidence of the Hereford map to show how imperfect geographical information was at a much later date, when even the Principality of Wales was supposed to be a separate island, we can, without much difficulty, admit that the term was applied generally to Cornwall. The evidences of very ancient tin-workings are still to be found in many parts of this county, and of Devonshire. In St. Just, near Cape Cornwall, are some rude workings upon the run of the lodes, and there are still remaining evidences in other parts of that parish, and in the adjoining parishes, which are probably early British. Some of the most remarkable workings in the county are, however, to be found in Gwennap, and in Baldhu. Again, in St. Agnes and in Perranzabuloe there are excavations showing that remarkable want of engineering knowledge which distinguishes all early workings. Around St. Austell we find similar evidences, and again in the neighbourhood of Calstock. Especially at Drakewalls like excavations—open to-day—exist. On Dartmoor these are numerous, and the extensive workings at and near Birch Tor are probably the most extraordinary existing.

Many of the old mine workings belong, without doubt, to the Roman period; and there is evidence that the educated skill of the Romans was brought to bear upon the Cornish tin mines. Many years since, when examining the workings of the lode in Baldhu, I heard of a well-executed adit having been discovered which had been driven up to the lode; and Mr. Enys informs me that he has learnt, on good authority, that "there was a large *arched stone level* in the elvan that runs through the district, very different from any other of the old men's workings, but that it was almost impossible to get near it at present without extreme danger." This description agrees with that of the Roman works in Spain.

Again, numerous "old men's workings" must belong to the reign of King John, when mining for tin was carried on most actively. I have but little doubt that nearly all the perforations in the cliffs of the tin district—such as are seen in a most remarkable manner in the granite at Cligga Head and scattered along the cliffs in St. Agnes and Perranzabuloe—belong to this period. That very extensive mining operations were carried on at that

time on Dartmoor is certain; and evidences of the existence of a large population still remain. The singularly isolated churches on the moor are all supposed to be of this date.
